The number of requests for admission to hospital, Dr. Brooke said, was so great that the formation of a waiting-list was misleading to prospective patients. It raised unwarranted hopes of a bed, hopes doomed to disappointment from the start. There were beds in the hospital, but no staff to care for additional cases. Part-time nurses or W.V.S. personnel could not do night duty, even if they helped by day. In fact, the only place where it was possible for these patients to get attendance at night was in their own homes. Since it was not possible to treat them in hospital, the aim must be to bring hospital facilities to the home.

Faced with this problem, his first step was to send a geriatric social worker to see those elderly patients he had been asked to admit but could not accommodate. The first difficulty had been that of providing suitable meals for patients who had nobody to cook for them. To meet this situation his hospital management committee had convened a meeting of representatives of the county health services, the county social welfare services, at the assistance board, with general practitioners from the local executive council. As a consequence of this meeting a standing liaison committee was formed to put into effect the recommendations of the B.M.A. Committee on the Care and Treatment of the Elderly and Infirm.

It was found that transport would be necessary to bring sitting and lying patients up to the hospital for out-patient examination and physiotherapy. A hot meals service was instituted by the W.V.S. This was the "meals on wheels" service. A laundry service for patients' dirty linen had been established using the hospital as a headquarters for collection and delivery. Routine contacts were made with district nurses, the home-help service, Red Cross workers, the W.V.S., occupational therapy teachers, and finally those who were willing to shop for the sick and to visit them from time to time. In many cases it was found possible to arrange for a service of "patient-watchers" among neighbours. This scheme was possible only where the co-operation of the general practitioner was forthcoming. The motto was, "Everything possible short of admission to hospital."

At present the system was in its infancy, but during the first three months of its life it had helped 100 patients who could not otherwise be cared for at home yet who could not be admitted to hospital. The visits of the geriatric social worker had been most useful in deciding the priority of cases for late admission. As a general rule two types of cases were given priority: those who could benefit by medical treatment within a short time, and those who were very ill under unsuitable home conditions. It was claimed that the service given by the system, however imperfect, was better than allowing patients to remain at home without such assistance, or than putting the names on a meaningless waiting-list.

The Ministry of Health has prepared the *Handbook for General Dental Practitioners* for the guidance of dentists taking part in the National Health Service. It describes the provisions of the N.H. Act and of the regulations up to November, 1948, as they apply to dentists. Copies have been sent to local executive councils for distribution to dentists on their lists.

Correspondence

Classical Caesarean Section

SIR,—The remarkable thing about the correspondence on classical caesarean section, the lower-segment operation, and rupture of the uterus (Sept. 25, 1948, p. 602, Oct. 16, 1948, p. 722, *et seq.*) is that it should take place at all. It is twenty-eight years since Eardley Holland and Munro Kerr introduced the lower-segment operation in this country, and about the same time since Beck, of Brooklyn, and DeLee, of Chicago, popularized it in America. Prior to that the essentials of modern technique had been well established by several Continental obstetricians. In a few years that followed the superiority of the operation became manifest, and the position was now reached (or so one had supposed) when caesarean section means the lower-segment operation unless otherwise stated.

With many of the points raised by your correspondents I entirely agree; no operation, however good, is applicable to every case irrespective of the particular conditions present. What the conditions are that occasionally prohibit the use of the lower-segment technique have been clearly summarized by Mr. C. Scott Russell (Oct. 16, 1948, p. 722)—almost the only champion of the lower-segment operation in this correspondence. So far so good. But what disturbs me is that the many letters have collectively conveyed an impression that the contraindications to the lower-segment section are so many and the difficulties are so great as to make it more or less a "stunt" operation. Those surgeons who still routinely employ the classical operation are thus confirmed in their complacency. This attitude I deplore, and for the following reasons.

Although the mortality rate for all types of caesarean section is now remarkably low, there is, so far as I know, no large series of consecutive cases (500 or more) which can show a mortality rate of under 1% save those in which the lower-segment technique was used (for example, the 0.4% mortality rate reported by Free).

The abdominal incision for the lower-segment operation is relatively small and is sub-umbilical; consequently there is seldom any exposure of the intestines. Theoretically this should lessen post-operative complications, and in practice I believe it does. Patients who have had the lower-segment operation generally make a quicker and easier recovery than do those in the other group, and the testimony of women who have experienced both operations is often eloquent on this point. After the classical operation the intestine sometimes adheres to the abdominal scar or, oftener, to the scar in the uterus. Obstruction is then a possibility, and may occur early by the involuting uterus dragging a loop of ileum down into the pelvis. This complication does not occur after the lower-segment operation.

It is generally stated that 4% of "classical" scars rupture in subsequent pregnancies (this figure would undoubtedly be higher if abdominal section were not so often again employed before the onset of labour). With the lower-segment technique the risk of rupture is greatly lessened. The uterus is incised in a part that is inert and which can therefore heal quietly and soundly. Firmness of the scar is further ensured by reinforcing the suture line by a layer of fascia or a fold of uterine muscle—a procedure that is impossible in the case of the other operation. Finally, it is unlikely that the placenta will become implanted over the scar in a subsequent pregnancy—a happening which it is generally supposed strongly predisposes to rupture.

Because of these facts rupture of a lower-segment scar is an unusual event and is estimated to occur in only 0.25% of cases. On this reckoning the risk of rupture is therefore only one-sixteenth of the risk associated with the classical operation. Convincing evidence of the increased safety is also found when the uterus is examined at a subsequent operation. It is seldom indeed that the "classical" scar does not show, in the emptied uterus, as a long, deep furrow, whereas the lower-segment scar is only rarely identifiable—far less does it show as a weakened area.

The slight delay in extracting the foetus is sometimes cited as a point against the lower-segment operation, and it is alleged

that the establishment of foetal respiration may be delayed by the relatively large amount of anaesthetic which the foetus absorbs. This difficulty, if it exists, is largely overcome by the careful choice and competent administration of the anaesthetic.

So convinced am I that the classical caesarean section is now superseded that I should be disturbed if I heard that any friend of mine had been subjected (without good reason) to that operation. And if at some subsequent pregnancy she had the misfortune to suffer a rupture of her uterus my thoughts would be bitter as well as sad.

I was once asked by an eminent gynaecologist what type of operation was being employed in my country. When I answered, "Usually the classical operation," he shook his head sadly and replied, "I cannot understand the mentality of anyone who still uses the classical section." That was eighteen years ago; how much more forceful his words have now become.—I am, etc.,

Spinal Anaesthesia for Caesarean Section

SIR,—If an anaesthetic technique is popular with some and condemned as dangerous by others, it means either that some are lucky when they have no trouble or that the others are violating some sound principle of anaesthetics. Many gynaecologists regard spinal analgesia in caesarean section as a procedure fraught with danger of sudden death to the mother, a danger which cannot be predicted in any particular case and about which nothing can be done. Some believe there may be biochemical changes, subtle enough to be indefinable, in pregnant women which make them liable to collapse under spinal anaesthesia. There are indeed sudden deaths in these circumstances, but I believe they are subject to a straightforward explanation and that they are preventable.

A spinal anaesthetic for a moderately high abdominal operation inevitably paralyses the nerve supply to the lower intercostal muscles, so that the lower and mobile part of the chest wall is temporarily put out of action. A full-term uterus splints the diaphragm, and the effect of this is increased by the Trendelenburg position and surgical packs. All that remains is for the surgeon's assistant to lean on the patient's chest to complete the insult to her respiratory mechanism. Even without this last there is a probability of collapse from anoxia if the patient is breathing air only. If she breathes oxygen, or there is means to inflate her with it, I believe the maternal risks are no greater than with other means of pain relief for this operation.

I am prepared to advance what I believe to be cogent arguments in favour of the trouble all being due to respiratory embarrassment, but at this stage I feel it is more profitable to end with a warning—but on behalf of the foetus. Contraction of the uterus is a notable feature of spinal analgesia, and it appears to increase with the passing of the minutes; time therefore must not be wasted. On one occasion I gave a spinal anaesthetic for a caesarean section because of placenta praevia. After the injection the diagnosis was confirmed by surgeon and assistants and the operation thus delayed some 30 minutes. Before the injection the foetal heart sounds gave no cause for alarm, but when the uterus was exposed some 50 minutes later it was tightly contracted, firmly gripping the foetus, which was found to be dead. On another occasion, with a different gynaecologist, there was a delay of some 20 minutes before the operation commenced, and my colleague, before opening the uterus, commented that so tightly was it applied that it almost revealed the sex of the foetus. In this case the infant was little the worse for the experience.—I am, etc.,

R. R. MACINTOSH.

Vitamin E in Heart Disease

SIR,—In the *Sunday Express* of Feb. 20, 1949, "Doctor M.P." writes an article under the heading "A medical discovery 'as great as insulin.'" He discusses the use of alphatocopherol (vitamin E) in heart disease and states that this drug "has been proved in my view as a doctor to show miraculous results in angina pectoris, in certain kidney diseases, and in

... Buerger's disease." He further asserts that its discovery is "officially recognized and proclaimed as one of the most beneficent in medicine since the introduction of insulin in 1922." He proceeds to upbraid the Ministry of Health for refusing to arrange for the import of "Vita E," which is being manufactured in Toronto.

Since Vogelsang, Shute, and Shute¹ published a series of articles on the use of vitamin E in heart disease, in which they claimed marked improvement in cases of angina pectoris and rheumatic and hypertensive heart disease, several workers in different countries have reported their failure to confirm these findings. Baer and his colleagues² found only questionable improvement in 6 out of 22 patients with congestive failure, angina pectoris, or hypertensive heart disease. In 11 similar cases Levy and Boas³ found no clinical evidence to warrant the use of vitamin E. From a controlled study of 22 cases Makinson and his colleagues⁴ concluded that vitamin E is of no therapeutic value in the routine treatment of angina pectoris. Gram and Schmidt⁵ found no improvement in 63 out of 80 patients with heart disease (mainly arteriosclerotic) treated with vitamin E. Ball⁶ found definite improvement in only 2 out of 10 cases of angina pectoris. Furthermore, not a single favourable report on any controlled observation of vitamin E in heart disease could be found. No controls were used in the series treated by the Shutes.

I should like, therefore, to make a strong protest against these observations of "Doctor-M.P." in a national newspaper. As a result of his article patients will undoubtedly harass their doctors to give them vitamin E. If they can get this drug their faith in it may result in some temporary improvement, as so often happens in cases of angina pectoris. But to buoy up the hopes of the many sufferers from heart disease with such dubious evidence is surely quite unjustified. From the reports already quoted the assertion that vitamin E is officially considered a great discovery is completely without foundation. In a panel discussion on cardiac therapy at the 1947 meeting of the American Medical Association⁷ it was stated that vitamin E is of no value in coronary heart disease, hypertension, or rheumatic heart disease.

There might be a case for even further controlled experiments on alpha-tocopherol (obtained either in this country or from Canada). But there is no case for presenting vitamin E to the public as a great medical discovery for the treatment of heart disease.—I am, etc.,

Nuffield Hospitals Trust

SIR,—The annotation (Feb. 19, p. 318) covering the recent report on the work of the Nuffield Provincial Hospitals Trust includes one curious and, I must suppose, unintentionally inaccurate sentence. This reads as follows:

"Among other projects supported by the Trust, always with a view to the better co-ordination of hospital services, the most noteworthy was the setting aside of £100,000 for the creation of the first professorship and Institute of Social Medicine in Great Britain—at Oxford under Professor J. A. Ryle."

The Chair and Institute at Oxford have never, of course, been concerned in any way with the co-ordination of hospital services. The purposes of the Institute, as laid down in the Resolution of the Trustees (1942), are as follows:

- (a) To investigate the influence of social, genetic, environmental, and domestic factors on the incidence of human disease and disability.
- (b) To seek and promote measures, other than those usually employed in the practice of remedial medicine, for the protection of the individual and of the community against such forces as interfere with the full development and maintenance of man's mental and physical capacity.
- (c) If required by the University to do so, to make provision in the Institute for the instruction in Social Medicine of students and practitioners of medicine approved by the Board of the Faculty of Medicine in the University of Oxford.

During the six years following its inauguration I hope that the academic activities of the Institute, including the publication of some 50 papers by members of the scientific staff, have sufficiently established its claim to be working towards the fulfilment of these purposes. Medical economics and administration, much though they stand in need of careful study, are not within our terms of reference.—I am, etc.,

Oxford.

JOHN A. RYLE.

* Professor Ryle is right. The error arose through the fact that in the report of the Nuffield Provincial Hospitals Trust the work of the Institute of Social Medicine was described in a section headed, "Some Projects Supported by the Trust Towards the Better Co-ordination of Hospital Services."—Ed., *B.M.J.*

Illness in General Practice

SIR,—The interesting article by Dr. John Pemberton (Feb. 19, p. 306) would have been more interesting and informative if he had carried the analysis of his data a step further. Neglecting the two categories accidents and obstetrics in Table IV, a statistical examination of the variability of diagnoses supplied by the seven doctors reveals discrepancies of a size that can hardly be ascribed to chance.

The difference between the average number of diagnoses in each category and that of the individual doctors can be expressed as follows:

Doctor	χ^2 Test	Contribution by:
A	44.16	Cardiovascular disease in excess 38.4
B	44.78	Cardiovascular disease in excess 29.4
C	11.51	Deficiency in mental ill-health 7.25
		Deficiency in cardiovascular disease 8.2
D	4.72	Insignificant difference
E	9.72	Rheumatism in excess 8.35
F & G	13.97	Equal spread over categories
H	11.54	Deficiency in mental ill-health 9.3

The χ^2 value of 9.5 signifies a difference expected only once in 20 samples, while a value of 13.3 is expected only once in 100 samples. There are two possible explanations of these differences: (1) age groups or social or geographical influences affecting the various practices; and (2) variations in the judgments of the doctors concerned.—I am, etc.,

Sheffield.

E. J. G. BRADFORD.

Pulheems

SIR,—With reference to "Surgeon-Lieutenant's" letter (Feb. 5, p. 244) I am not in a position to comment on the application of the Pulheems system in the Royal Navy, with which the writer's letter appears largely to deal, but I can clarify the situation slightly in so far as the Army's application is concerned.

I agree with "Surgeon-Lieutenant" that in Service life it would be more valuable to fit the man's duties to his previous occupation, and this in fact is the duty of the personnel selection officer in the Army. With regard to the length of time Pulheems examination takes, "Surgeon-Lieutenant" will agree that Pulheems is merely a new method of recording findings on medical examination, and, if the doctor examining the patient knows the system of medical classification he is going to use, the additional time taken to record the findings in accordance with Pulheems is no greater than with any other system.

All entrants to the Services are examined by the civilian medical board of the Ministry of Labour and National Service, whose examination is complete. These boards consist of four medical officers, one chairman, and one orderly, and the boards are able to complete the examination of 20 men in 2½ hours (Supplement, Feb. 12, p. 74). On these medical boards lies the responsibility to certify that the individual entering the Service is fit for service.

This being the case, the first examination of all new entrants to the Army is merely a verification of the findings of the civilian medical board, taking into account their medical report and the history given by the individual regarding the period which has elapsed since the civilian board examined him. The finding of the medical officer in this instance is taken as the individual's initial Pulheems assessment, and after a period not exceeding four months the individual is again examined and given a Service Pulheems assessment, which is based on the

The Delicious Nourishing, Energising Vitamin Food

for Infants, Children & Adults
at all Seasons

BY providing a valuable nutritive element and vitamins in a delicious form, Vimaltol offers special advantages everyday to the physician. With delightfully pleasant orange flavour Vimaltol is readily acceptable to every patient.

Vimaltol is made from specially prepared malt extract which is high in protein content, yeast—one of the best sources of Vitamin B₁ and Halibut Liver Oil—an important source of Vitamin A and D. It is also fortified with additional vitamins and mineral salts and is deliciously flavoured with orange juice.

Vimaltol is carefully analysed and found to contain in each fluid ounce: 100 units of Vitamin D, also 0.3 milligrammes of Vitamin B₁ (P.P. vitamin) and 4.2 units of Vitamin A in a concentrated form.

Vimaltol is an important therapeutic agent in the treatment of certain essential deficiencies which result in abnormal growth and development of the growing child, e.g. in the maintenance of the general resistance against infection.

Vimaltol is recommended with advantage at all seasons and for all patients.

terms of  **TONIC** value

The value of a tonic cannot be measured in simple numerical units. But the essential features of such a preparation can be placed under well-defined functional headings . . . *restoration, formation and protection.* Syrup Minadex is well equipped to fulfil these functions. Iron, calcium and other minerals comprise the stimulatory and formative elements of Minadex. The vitamins A & D of Minadex are valuable in a protective sense. Combined in an orange-flavoured syrup enjoyable even to the most fastidious patient, these factors restore lost appetite and hasten the return to full health.

GLAXO

SYRUP MINADEX

In 6 oz and 12 oz bottles

Each fluid ounce contains : Vitamin A 18,000 i u Vitamin D 3 000 i u Iron and ammonium citrate 13½ grains. Calcium glycerophosphate 2 grains, potassium, sodium, and manganese glycerophosphates; copper sulphate.

findings on examination and on the experience of the individual during his period of training by both the medical officer and the training officer. Army experience shows that both these examinations can be carried out quite adequately allowing 10-15 minutes per man.

The other point which is, I think, relevant is the fact that 90% of Service intakes are fit men who can be dealt with very quickly, leaving more time for the remaining 10% who are not so fit. The time taken to examine a man will depend on the purposes behind the examination and the object of it and may vary from 5 minutes to 30 or even 40 minutes, depending on what the doctor is looking for and what he finds.

If "Surgeon-Lieutenant" cares to study the instructions and literature available on the grading system of classification formerly used by the Ministry of Labour and National Service, also by the Royal Navy and the Royal Air Force, and the old medical category system used by the Army, he will not doubt realize why I have said that Pulheims goes a long way towards unifying and rationalizing our standards and towards improving our clinical appreciation of physical and mental health—I am, etc.,

London, S.W.1.

Oral Reactions to Penicillin

SIR,—In a paper carrying the above title, recently published in this *Journal*, Dr. W. G. Cross (Jan. 29, p. 171) quotes among others a paper by Ellinger and Shattock (Oct. 26, 1946, p. 611). Dr. Cross states that Ellinger and Shattock had described the oral reaction to penicillin—i.e., a slaty discoloration of the tongue following local application—"as largely one of nicotinamide deficiency." Ellinger and Shattock reported the case of a woman who had previously shown clinical signs of nicotinamide deficiency, and who developed pellagroid symptoms after local treatment of the mouth with penicillin, particularly of the central and peripheral nervous systems, and simultaneously a slaty discoloration of the tongue, unknown in human, but common in canine, nicotinamide deficiency. It was possible to repeat in the same person the precipitation of pellagroid conditions, as well as discoloration of the tongue, by renewed local application of penicillin and to investigate simultaneously the urinary elimination of nicotinamide metabolites. The latter were found to be diminished during penicillin application, thus confirming the presence of nicotinamide deficiency. The authors stated, contrary to the quotation of Dr. Cross, that probably "the changes observed are partly due to a local effect of the drug on the tongue," and that "the local effect causing the darkening of the tongue has still to be investigated."

Cross claims in the summary of his paper that "neither nicotinamide deficiency nor . . . is responsible for the oral reactions." We do not know on what evidence this statement is based. He does not mention examination of the elimination of nicotinamide derivatives, the only reliable basis for the diagnosis of a nicotinamide deficiency. If, as it seems, his statement is based on the fact that the inclusion of the totally inadequate amount of 2 mg. of nicotinamide in the penicillin tablets did not prevent the development of darkening of the tongue, then his statement is inconclusive. When for some reason or other the nicotinamide-releasing intestinal bacteria are out of action about 100 mg. of nicotinamide daily for several days is needed to prevent, and 200-500 mg. daily to cure, a nicotinamide deficiency.—We are, etc.,

P. ELLINGER.

Epilepsy and Foetal Behaviour

SIR,—I have hesitated to reply to Dr. Thomas D. Power's question under this title (Jan. 29, p. 197) because I have not sufficient knowledge of physiology and, in particular, the work of Coghill and Barcroft on primitive behaviour. With this reservation, however, I must say that the theory that an epileptic fit is a reversion to a foetal level of nervous function does not appeal to me. The epileptic convulsion is not explainable solely by the release of lower functions, but must include also pathological overactivity of cortical neurones. Furthermore, behaviour in a fit is not always "total," but may be exquisitely localized.

Finally, it is not correct to describe movements in a fit as spastic, as this is a term which applies to a state of muscle tone and not to movements.—I am, etc.,

Newcastle-upon-Tyne

F. J. NATTRASS

Approach to the Frontal Lobe

SIR,—Psychosurgery is certainly not without its faults and cannot be defended as a perfect type of psychiatric treatment, but it should not be the subject of seemingly ill-informed attacks such as the counterblast by Dr. P. Glees (Jan. 29, p. 193).

The "new access" recommended by Freeman was in fact explored as an experimental approach by Fiamberti, who published his results in 1937. After careful anatomical studies indicating that a type of transorbital lobotomy did in fact sever the thalamic connexions of areas 9 and 10, as in the more conventional topectomy operation, Freeman began to direct a series of transorbital lobotomies in 1946.

The "predictable results" for which Dr. Glees asks may be shown by the preliminary report of Jones and Shanklin¹ and by Freeman's² comments on a series of 100 cases. Favourable response was claimed in one-third of the schizophrenics and one-half of the involutional cases. The "serious consequences" feared by Dr. Glees can be stated more explicitly—two cases in the series showed complications, and the absence of "unfavourable personality symptoms noted after prefrontal lobotomy" is commented on.

The "indications for a lobotomy operation" are admittedly not yet as clear as one could wish, but the field is not altogether untilled. May I refer Dr. Glees to Kalinowsky and Scarff,³ *The Selection of Psychiatric Cases for Prefrontal Lobotomy*, or the U.S. Veterans Administration publication, *Criteria to Guide in Selection of Patients for Prefrontal Leukotomy*? If those do not sufficiently represent "a united effort of research and clinical observation" Dr. Glees should try the sixth report of the Group for the Advancement of Psychiatry, *Research on Prefrontal Lobotomy*, or perhaps he will be better pleased with *The Human Frontal Lobe*, which represents the observations of a medical-surgical scientific group of 96 collaborators.—I am, etc.,

Fibrositis

SIR,—The letter of Dr. J. H. Milner (Nov. 27, 1948, p. 955) forces me to continue a fruitless discussion reluctantly. Naturally I could in my letters only mention the fundamental conception of diminished blood flow leading to hypoxia in the myalgic spots, which, I added, might be caused either by vasoconstriction or vasodilatation. I stressed that the details of the theory are given in a special paper the publication of which I am sorry to say has been delayed.

Dr. Milner, now following Dr. Cyriax, postulates a host of pathological processes of a purely theoretical nature for fibrositis. If not psychogenic or imaginary the processes are in the cervical spine, and he mentions the results of prolonged degenerative processes or a more severe single trauma, giving way of the disk, approximation of the vertebral bodies, marginal lipping, osteophytes, etc. For these assumptions not a shadow of positive evidence is adduced. On purely theoretical grounds it is postulated that root lesion is present in primary fibrositis.

The assumptions put forward do not stand a logical analysis. First, the symptoms and signs of fibrositis do not correspond to a spinal-root lesion. Secondly, it is a fact that "fibrositis" can be cured by injection of procaine into each myalgic spot—this could not be possible if it were caused by a root lesion. Lastly, Dr. Milner suggests "that fatty herniae may occasionally be the result of fatty degeneration of muscles and their fasciae," a view which runs counter to the fundamental conceptions and findings of modern pathology and which will make R. Virchow turn in his grave. He claims that his views "harmonize with proven first principles." One must ask, What are these principles?—I am, etc.,

London NW 11

M. G. GOOD

Whither Tuberculosis?

SIR,—The airing of a subject, even so big and complicated as one as the present position of combating tuberculosis, in your correspondence columns is most helpful. May I reiterate some of the points I tried to make in my previous letter?

(1) Complications will be clarified by bearing broad principles in mind, for sometimes these are forgotten in a maze of "directives" and a multiplication of officers, clerks, forms, and regulations.

(2) Regulations and "directives" should lessen and not increase overlapping.

(3) In any disease, and especially in dealing with tuberculosis, the interplay of cause and effect, of prevention and treatment, must be grasped. But the recognition of such interplay should prevent individual doctors and their assistants from attempting to encompass too much. They must be guarded against trying to do too many jobs.

The Lancashire team without doubt pursued a straight path, trod a well-paved road up to "the crossroads." The road now may not be so straight and well paved. Much new ground has to be covered. For example, mass radiology must be developed in ways recent experience has taught us. B.C.G. vaccination should be extensively used. Dr. G. Lissant Cox, especially if ever vigilant to observe the points I have mentioned above, can still help.

There is a dangerous trend to-day—namely, belief in and exaltation of supermen. Whether such be chairmen of important advisory committees, or paymasters-general in big regions, or others in high positions, we must be careful not to count them as godlike Führers. Fortunately in our fight it is the prowess of the individuals in the fighting line which counts for success, as Dr. W. H. Tattersall has indicated in his letter (Feb. 19, p. 322).

I was perhaps to blame for reference to an unimportant detail in my last letter. But it appeared to me and many of my friends that my fellow Liverpudlian, Dr. Lissant Cox (apparently all the best people were born in Liverpool! But what has that got to do with the argument?), did not help clear thinking by misusing the word "directive," which until a few years ago was used only as an adjective, by saying a disease can merge into a directive. He could have expressed his meaning, I think, more clearly. And it was rather unnecessary to bring out what surely everyone working on tuberculosis in England knows—that public health committees have been eroded by regional boards. This has been observed even those privileged to live "in a far corner of a minor county." am, etc.,

Fundesley, Norfolk.

S. VERE PEARSON.

Unusual Case of Twins

SIR,—The case here recorded occurred by a coincidence on the day of publication of an account by Drs. J. H. Young and F. E. Cull (Oct. 16, 1948, p. 713) of an unusual case of twins. The unusual sequence of events during labour is of interest in both cases.

A multigravida, aged 31, attending the antenatal clinic during the 37th week of pregnancy, was diagnosed as having twins. She had had normal deliveries of living children in 1942, 1944, and 1946. Her health had been good throughout the existing pregnancy. X-ray examination confirmed the presence of twins, showing one child lying as a breech presentation with the back to the right, the other as a transverse occupying the fundus uteri with the head to the left. At 38 weeks the foetal presentations were diagnosed by palpation as a vertex and a breech, both presenting parts lying above the pelvic brim.

Labour began on Oct. 15, at 1 a.m., the patient having reached full term. She was admitted to hospital at 11 a.m. on the same day. On examination the foetal positions were diagnosed as L.O.A. and R.S.A. respectively. Pains were strong, and at 1.45 p.m. a vaginal examination showed the os to be fully dilated, the vertex low, and the position an L.O.A. The membranes were ruptured during the examination. The first child was delivered normally at 2.40 p.m. and cried well. At 3.15 p.m. a vaginal examination was made with a view to rupturing the second bag of membranes, but no membranes could be felt. The breech was low and the position an R.S.A. At 3.25 p.m. the second infant was born as a breech completely enclosed in an apparently unruptured caul. The edge of the placenta appeared on the left side when the child was born as far as the scapulae, and the placenta was expelled complete with the rest of the

ovum. On rupturing the caul to free the child it was noticed that there were two layers of membranes over the child's face, the more superficial layer being found to consist of part of the membranes of the first child. There appeared to be little or no amniotic fluid inside the caul, suggesting that a small invisible rupture had occurred early and explaining the difficulty of feeling the membranes on vaginal examination.

At 3.30 p.m. signs of separation of the first child's placenta were recognized. On expulsion it was found to be complete except that a portion of the membranes was torn away from one side, corresponding to that found over the second child's face.

The infants were both live males and were dissimilar in appearance. The first weighed 5 lb. 4 oz. (2.4 kg.) and its placenta 18 oz. (510 g.). The second child weighed 6 lb. 2½ oz. (2.8 kg.) and its placenta 21 oz. (594 g.).

A summary of the course of events in this labour will serve to emphasize the points of interest: (1) Normal birth of the first child as a vertex. (2) Extrusion of the complete ovum containing the second child together with a portion of the first child's membranes. (3) The expulsion of the first child's placenta after the second child's birth, with part of the membranes missing.

I should like to express my gratitude to Mr. Albert Davis and to Dr. S. G. Chapman for their kind advice and permission to publish this report.

—I am, etc.,

London, S.W.10.

J. F. T. ALLISON.

Treatment of Varicose Veins

SIR,—Professor A. M. Boyd and Mr. D. J. Robertson published an article in the *Journal* on varicose veins, mentioning particularly recurrences after treatment and the risks of giving retrograde injections during the operation of saphenous ligation. This warning was substantiated by phlebographic studies carried out by injecting radio-opaque material at the fossa ovalis and at the knee. As the material was shown by x ray to enter the deep veins, particularly in the thigh, it was considered dangerous to give an injection of sclerosant for fear of causing deep-vein thrombosis. The danger was greater in the thigh than in the leg.

Atlas also stated that retrograde injection was hazardous and should not be done. On reading this latter article I did a series of phlebograms to find out what happened to material given as a retrograde injection. I found that material injected into the long saphenous vein entered the deep system whether the injection was given retrogradely from the fossa ovalis and knee or from below upwards at the ankle. A deeper shadow was obtained in the leg than in the thigh. My conclusion was that retrograde injection from the fossa ovalis was safer than from the knee, because the opaque material was diluted and swept away more rapidly in the thigh than in the leg. Both my findings and my conclusions were the very reverse of those of Professor Boyd and Mr. Robertson.

I am not suggesting that I am right and they are wrong, or vice versa—phlebograms are very tricky things. I am suggesting that such conflicting evidence should keep our minds open on this problem. We have not proved very much, for we knew beforehand that the blood goes from the superficial to the deep veins, and the position of the main communicating veins has been known for a long time. I certainly feel that no case has been established for abandoning retrograde injections.

This is such a useful ally to ligations—one or more—that it should be continued; but it should be used with care and skill. Standard massive doses of strong sclerosants should be abandoned, and minimal amounts of minimal strength solutions consistent with obtaining thrombosis should be used. The quantities and strengths to be used vary with each patient and are arrived at by experience. It is safe to say, for instance, that using "ethamolin" one is never justified in injecting greater than half-strength, while in the majority of cases one-third strength is sufficient. Let us not abandon so useful a form of treatment on insufficient evidence of its danger, but rather let us find out how to use it safely.—I am, etc.,

Sydney, Australia

Anæsthetic Problems

SIR,—I have followed with close interest the correspondence on two anæsthetic problems. First, the question of spinal anæsthesia for caesarean section. It is of course a satisfactory method in selected cases and in expert hands. Two important points are to control any drop in blood pressure and to ensure oxygenation of the patient. Indications for its use are nowadays fewer with the use of *d*-tubocurarine and light general anæsthesia with cyclopropane or ether in a closed circuit. Excellent operative conditions are achieved with good retraction of the uterus; the baby is active and the mother very well post-operatively.

Secondly, the use of surface analgesics in endoscopic examinations. At the gynaecological clinic at the Royal Sussex County Hospital we have for the past three years been using *d*-tubocurarine and sodium thiopentone with excellent results and, considering the poor condition of most of the patients, with very little anxiety. Here again adequate oxygenation is absolutely necessary. I have no doubt that from the patients' point of view this type of anæsthesia is far preferable to local. They are mostly awake within ten to fifteen minutes of the examination.—I am, etc.

Hove, Sussex

J. H. CRAWFORD

Temperature Recording

SIR,—We all rely so much on clinical thermometry that its accuracy is a matter of extreme importance; therefore the communication of Professor Alan Moncrieff and Dr B. J. Hussey entitled "Temperature Recording in Sick Children" (Dec. 4, 1948, p. 972) and your annotation on "Temperature Recording" (p. 991) are welcome and timely.

One definite advance has been made in clinical thermometry during the past ten or fifteen years. No one believes now that a half-minute thermometer gives a correct temperature if placed in the axilla for half a minute. It was not always so. To get an accurate temperature in the axilla the skin should be dry and nothing should interfere with the closest possible approximation of the sides of the axilla. No dressing-gown, nightgown, or pyjama must interfere with this approximation. For five, ten, fifteen, or twenty minutes the thermometer must remain *in situ*, until the temperature in the axilla equals or at least closely approximates to the temperature of the body. It is impossible to say how long that may take. Clearly, if the surface of the body is cold or if the patient is emaciated it will take a longer time than if he were warmly covered up in bed or well nourished.

For quick and accurate thermometry the rectum is the one place in which a half-minute thermometer will give an accurate record in half a minute. Two points must, however, be observed: the bulb of the thermometer must be in the rectum, and the patient must be at rest for at least half an hour before the temperature is taken. If taken immediately after exercise a temperature of 101° F. (38.3° C.) may be found in a perfectly healthy person.

This letter would probably never have been written but for a statement in the last paragraph of the annotation: "Frequently insufficient care is taken in the length of time a thermometer should be left in position; at least two minutes for a half-minute thermometer." Such a procedure will rarely, if ever, give an accurate body temperature in either the axilla, the groin, or the mouth. The mention of two minutes, even if qualified by "at least," is, I think, most unfortunate, and I deeply regret the suggestion of such a time limit.—I am, etc.,

Dublin

ALFRED R. PARSONS.

SIR,—Now that the seasonal outbreak of correspondence on the subject of temperature recording has occurred, may I add my contribution? A clinical thermometer bearing the N.P.L. (National Physical Laboratory) monogram can be relied upon to measure accurately the temperature of anything in contact with the bulb within the limits (0.2° F.) stated in the certificate and in the time stated. To suggest that it takes longer is derogatory to that institution.

The reason why a thermometer may not record the true temperature of that part of the body into which it is inserted until

some minutes after the time etched on the thermometer is that a cold thermometer chills the tissues with which it is in contact, and these may take some minutes to regain their original temperature. The thermometer will accurately record at the half-minute (or whatever the particular time may be) the temperature of the chilled tissues. The length of time that it takes, therefore, to record the true body temperature will depend mainly on how cold the thermometer is to start with, and this naturally varies on different occasions.

A simple method of measuring the true sublingual temperature in just a trifle longer than the time stated on the thermometer is to place the bulb under the tongue on one side for a quarter of a minute, and then, without removing it from the mouth, to place the bulb under the other side of the tongue for the requisite half-minute or so. By placing it on one side first, the temperature of the mercury in the bulb is brought to within a degree or two of the true sublingual temperature. There is then no chilling effect on the tissues when it is placed on the other side. By this means a patient's temperature may be accurately recorded in three-quarters of a minute, instead of the ten minutes suggested by some of your correspondents.—I am, etc.,

London, S E 22

BERNARD FREEDMAN.

Proguanil in the Sudan

SIR,—In contrast to the rather disappointing results described by Dr. E. S. Walls (July 24, 1948, p. 225) of the use of proguanil ("paludrine") as a malaria prophylactic in Sierra Leone, I have found it extremely satisfactory in this district of the Southern Sudan.

The opportunities for estimating the value of a prophylactic drug are considerable in this area, for malaria is hyperendemic, with *P. falciparum* as the predominant parasite, and not only do many officials live in houses which are not mosquito-proofed (many such as myself prefer not to be hemmed in by mosquito wiring) but most spend a great deal of their time trekking in the forests, where the chances of being bitten by infected mosquitoes are great.

For the last two years I have carefully observed the results of various regimes of proguanil administered to British officials and Northern Sudanese Arabs under my care. The latter arrive in the area without any immunity to the local strains and appear to be as susceptible to malarial attacks as the British, though the severity of the attacks is often lessened—due no doubt to the non-specific resistance they have acquired by their experiences of the disease in the north. I have reached the conclusion that if proguanil in a dosage of 350 mg. or more per week is taken regularly (the easiest arrangement to remember is half a tablet at breakfast each morning) then the chances of acquiring an attack of malarial fever, in this district at least, are very small indeed. My conclusions are supported by the following figures.

Of 14 European adults taking three or more tablets of proguanil per week, two attacks of short-term fever (of unknown origin, but possibly malarial) were seen in an aggregate of 103 man-months at risk. Of four Northern Sudanese adults living in my compound and taking three tablets per week under my continuous supervision, two cases of short-term fever (again of unknown origin, but conceivably malarial) were seen in an aggregate of 21 man-months. In none of these cases were the fevers typical of malaria, and the blood films were negative.

By contrast, among 32 Northern Sudanese—who had in fact been issued with mepacrine, but few of whom took it except when they felt fever coming on—169 cases of "fever" occurred in an aggregate of 156 man-months at risk. The last figures are the result of a questionnaire and may be slightly exaggerated, for though I saw many of these cases, some with positive slides, most were self-treated with the mepacrine issued for prophylaxis and did not report to hospital. I feel, however, that it is near the truth.

Used in the treatment of M.T. malaria proguanil has been disappointing. In the recommended dosage of 100 mg. thrice daily for ten days it is certainly inferior to mepacrine or quinine as regards the rapidity with which the fever is reduced, and I have even seen positive blood films on the 5th day of such a regime. I have not at any time seen ill effects attributable to the drug itself.

It has been known for many years that malaria differs in different parts of the world. It differs in severity, clinical

manifestations, and in its reactions to various methods of treatment. Is it therefore surprising that the different strains should differ in their susceptibility to suppression or true causal prophylaxis by proguanil? Is it not rather more surprising that manufacturers of antimalarial drugs should confidently draw conclusions and issue instructions which they apparently intend to be of world-wide application when these are so often based on experiences in limited parts of the globe? At a time when many are leaving the home country to seek new lives abroad, your columns can help to teach the valuable lesson that advice on matters of protection against endemic diseases is best obtained from those with local experience, and that generalized advice may be misleading or inadequate.—I am, etc.,

LI RANGU, Sudan.

P. H. ABBOTT.

POINTS FROM LETTERS

Treatment of Simple Ganglion

Mr. H. J. NIGHTINGALE (Milford-on-Sea, Hants) writes: The correspondence on the treatment of ganglion reminds me of a method, not so far advocated in your columns, which I found in a surgical textbook some years ago. The author, whose name I have forgotten, prided himself on writing a book on surgery for the first time in English instead of Latin; he flourished in the reign of William and Mary. His methods for emergency surgery such as strangulated hernia were often excellent, and he even anticipated Lister by his repeated advice to wash the wound during the operation with spirits of wine. But when he came to the treatment of ganglion his surgical instinct was overcome by the older principles of magic. He advised first of all the family-Bible method (thus confirming your correspondent's idea that this technique dates from the days of Queen Anne), wisely suggesting that the force used should not be enough to break the bone. If this failed, he recommended binding on with plaster a piece of one of the heavy metals, "best of all a lead bullet that has killed one of the larger animals, such as a stag." But magic had its limitations even for him, and he mentions only to condemn in his more scientific days "such barbarous ideas as bringing the sufferer in contact with the hand of a corpse."

Penicillin Sensitivity

Dr. H. H. MARGULIES (London, N.W.2) writes: With reference to the recent frequent correspondence on the subject of penicillin sensitivity, I think that the following case may be of general interest. A boy aged 11 years, slightly plethoric, developed acute tonsillitis with a temperature of 102° F. (38.9° C.). I gave him 500,000 i.u. of oral penicillin daily for four days, and the condition has cleared completely. The boy was never given penicillin before. Fourteen days later the boy started to complain of pains in his wrists and ankles, and again shot up a temperature of 100° F. (37.8° C.). I found nothing abnormal on examination till two days later, when he developed a severe urticaria over the whole body coupled with considerable, very painful swellings in the joints of both elbows, hands, knees, and feet. He was given large doses of "benadryl" and aspirin, but the condition did not start subsiding till nine days later. It took over three weeks to clear completely, and the boy has still shown after seven weeks a tendency to urticarial weals on the slightest injury.

Classical Caesarean Section

Dr. C. UHMA (London, W.3) writes: In his letter (Feb. 5, p. 242) on the interesting problem of caesarean section Dr. Tim Boland does not state the type of case under his treatment. To judge whether the classical caesarean operation was rightly chosen it is very essential to know which followed—hysterectomy or myomectomy. In the first case it makes no difference if the lower-segment operation or the classical one was performed. In the second case it would be preferable, in my opinion, to perform the lower-segment operation after removing the fibroid as a whole than to make another incision for the classical section and so to extend the injuries to the uterus which was left.

Causes of Rib Fracture

Dr. A. H. MICHAEL-PHILLIPS (Littleborough, Lancs) writes: I am prompted by recent articles in the *Journal* to record the following. About two years ago I was called to visit a young woman of about 35 years of age who had severe pain in the left side. She had been out earlier that day with her young man, and on rising from the bank on which they had been sitting she felt something snap, "like a twig." She experienced a sudden sharp pain in her left chest and got home with difficulty. It seemed too slight a degree of trauma, but x-ray examination confirmed the diagnosis of a fracture of the left 7th rib.

Obituary

SIR WILLIAM HALE-WHITE, K.B.E., M.D., F.R.C.P.

Sir William Hale-White, who died at his home in Oxford on Feb. 26 at the age of 91, was well known as a clinician and teacher and as the author of a famous textbook. He was on the staff of Guy's Hospital for thirty-four years.

William Hale-White was born on Nov. 7, 1857, in London. His father, William Hale White, was a distinguished nineteenth-century writer who used the pseudonym "Mark Rutherford." Hale-White entered Guy's Hospital Medical School in 1875. He graduated M.B. with honours in medicine in 1879, and proceeded M.D. a year later. After qualifying, he was resident in Guy's Hospital as a house-physician, and was subsequently resident medical officer at the Evelina Hospital for Children. In 1881 he became demonstrator in anatomy at Guy's, and continued this work until 1885, when he was appointed assistant physician. He then took over the lectureship in materia medica, pharmacology, and therapeutics, and continued to hold this post until 1899, when he became lecturer in medicine.

It was in 1892 that the first edition of *Materia Medica, Pharmacy, Pharmacology, and Therapeutics* appeared. Its success was deserved, and it is still in demand. The twenty-sixth edition was published in 1944. A more elaborate work was the *Textbook of Pharmacology and Therapeutics* which Hale-White edited in 1901. Another book, *Common Affections of the Liver*, published in 1908, embodied his considerable experience of this subject as a clinician and as a teacher.

Hale-White was elected F.R.C.P. in 1888, and he was one of the examiners for the College for eight years. He was also censor, councillor, Croonian lecturer in 1897, and Harveian orator in 1927. His four Croonian lectures were concerned with the means by which the temperature of the body is maintained in health and disease. This was a subject to which Hale-White had for many years paid special attention. He had taken part in a discussion on pyrexia and its treatment at the Bristol Meeting of the British Medical Association in 1894, and had previously published papers in the *Journal of Physiology* "on a method of obtaining the specific heat of certain warm-blooded animals." The Harveian oration, "Bacon, Gilbert, and Harvey," was a consideration of the influence which men around Harvey might have had in encouraging him to investigate by experimental observation rather than by deduction from the opinions of previous workers.

During the 1914-18 war Hale-White was a brevet-colonel and consulting physician to a number of war hospitals and a member of the Final Medical Appeal Board. He was also chairman of Queen Mary's Royal Naval Hospital, Southend. In 1919, after twenty-nine years as physician to Guy's Hospital, he retired and was made consulting physician. In the same year he was created K.B.E. He was president of the Medical Society of London in the following year, and president of the Royal Society of Medicine in 1922-3. For many years he was treasurer of the Association of Physicians of Great Britain and Ireland, and much of the success of the Society, of which he was president in 1930-1, was due to his work for it.

Hale-White was much sought after by universities as an examiner first in materia medica and subsequently in medicine. He wrote many papers for *Guy's Hospital Reports* and for other medical journals. He was responsible for several articles in *Allbutt's System of Medicine* and in *French's Index of Differential Diagnosis*. After his retirement from practice

(Press Portrait Bureau)

Hale-White devoted himself to the study of medical history. He completed a short biography of Laennec in 1923, and in 1935 his *Great Doctors of the Nineteenth Century* was published. There followed in 1938 his book on Keats.

He married, in 1886, Edith Jane, daughter of Alfred D. Fripp, the artist, and sister of the late Sir Alfred Fripp, a colleague of Hale-White's at Guy's Hospital. She died on Nov. 30, 1945. Their only son is a physician in London, and to him the sympathy of many colleagues and friends will be extended.

Dr. FRANK PHILIP GILBERT DE SMIDT, who was 58 years of age, died at his home in Nairobi, Kenya, on May 19, 1948, after a long illness bravely borne. He was formerly officer in charge of the bacteriological section of the Medical Research Laboratory, Nairobi, and bacteriologist to Kenya. He was born near Capetown, and was educated in England at Brighton College and then at the London Hospital, where he qualified in 1916. After a period of active service in the first world war he took the D.P.H. and became a research worker in bacteriology for the Food Investigation Board of the Department of Industrial and Scientific Research. Later he held the post of assistant director of the clinical laboratory at the Manchester Royal Infirmary, and subsequently that of pathologist to the Brompton Hospital for Consumption. He then joined the colonial medical service and went to Kenya in 1926 to take up his appointment at the Medical Research Laboratory, Nairobi. There he carried out research on many subjects, notably on plague, pneumonia, and rabies. The vaccines which he prepared were used throughout East and Central Africa. He was the author of a number of papers on bacteriological subjects, and he was widely esteemed by his co-workers in the same field. After ten years in Kenya he was invalided out of the service, and during his remaining years he occupied himself as a member of the Rationalist Press Association of Great Britain and the Rationalist Association of Australia. Dr. de Smidt leaves a widow and a daughter, who is also a doctor.—A. E. R.

Dr. ELAYEDATH ACHYUTA MENON, who died on Sept. 7, 1948, at Irinjalakuda, Cochin State, was born in 1888, qualified in 1912, and served in Mesopotamia during the 1914-18 war. After a period as resident medical officer at the Rajah Sir Ramaswamy Mudaliar Lying-in Hospital, he came to this country and took the Edinburgh F.R.C.S. in 1927 before going out to the Tanjore and Royapuram medical schools, where he was lecturer in operative surgery. He was appointed professor of obstetrics and gynaecology at the Madras Medical College, and later he became assistant superintendent of the Women and Children's Hospital. Soon after completing his work there he took the M.R.C.O.G. From 1936 to 1944 he was professor of obstetrics and gynaecology at the Andhra Medical College, and he was on the staff of the King George Hospital at Vizagapatam.

Dr. EDWARD SEYMOUR CHAPMAN died on Jan. 14 at the age of 69 after a brief illness. He graduated M.B., Ch.B. at Glasgow in 1901, and in 1905 gained his doctorate with honours and won the Bellahouston Gold Medal. After holding resident posts at the Western Infirmary he was for two and a half years assistant physician at the Belvidere Fever Hospital, Glasgow. Chapman then went to the Hertford British Hospital in Paris for some four years, and he took the Edinburgh F.R.C.S. in 1911. After a short period in Southbourne, he came to Scarborough in the summer of 1914. In the first world war he was in the R.A.M.C. for five years, serving in Malta and India, and he became divisional surgeon specialist in Lahore. During his service he suffered a fracture of the skull which caused him much pain and illness on his return to civilian life. When he returned to Scarborough in 1919 Dr. Chapman was appointed to the staff of Scarborough Hospital, and was honorary physician there until he retired in 1938, when he became honorary consulting physician. For twenty-seven years he was the medical officer in charge of the venereal disease clinic in Scarborough. He was also appointed medical officer to the Royal Northern Sea Bathing Infirmary, Scarborough, in 1929, and he still held this position at the time of his death. For twenty years he had been a part-time referee for the Ministry of Health, chairman of the Scarborough National Service Medical Board, a member of the Disablement Advisory Committee, and medical examiner for the Civil Service Commission and for the Ministry of Education. In July, 1946, he was appointed master of the Dr. Smart's Homes at Scarborough. Dr. Chapman had always been a most active, loyal, and enthusiastic member of the B.M.A. He served on many committees, and was honorary secretary of the Scarborough Division from 1928. He was chairman of the Division in 1932-3, and

president of the Yorkshire Branch in 1946-7. All who knew Chapman realized his worth as a doctor and as a man. His capabilities were such that he enjoyed the respect of both patients and colleagues. He was a man of great integrity, and performed many good deeds quietly and unostentatiously. Scarborough has lost a good doctor in every sense of the word, and the public have lost a friend, counsellor, and physician whose place it will be difficult to fill. Dr. Chapman is survived by a widow, to whom the sympathy of all his friends and colleagues will be extended.—C. E. W.

Dr. URBAN MARKS died suddenly in his surgery at Swansea on Feb. 4 at the age of 68. He came to Swansea as house-surgeon to the Swansea Hospital forty-two years ago, and soon afterwards started in general practice in the town. He very soon built up a large panel practice. He was from the beginning an active member of the B.M.A. and became secretary and later chairman of the local Division. He was a founder member of the Swansea Public Medical Service, one of the first to be formed in the country, and was its chairman for many years. Dr. Marks was on the out-patient staff of the hospital for twenty-five years, being made honorary consulting physician on his retirement three years ago. He was actively concerned with hospital administration during the whole of this period. He was secretary and then chairman of the hospital medical staff, and he was also chairman of the Swansea Panel Committee. In 1941 he was appointed a member of the Medical Planning Committee of the B.M.A. For some years he had been a member of the old Swansea Board of Guardians, and he took an active interest in the St. John Ambulance Brigade. He was its commissioner in Swansea for twenty-six years. He became a Knight of Grace of the Order, and a member of the Ambulance Committee for Wales. During the recent war he was honorary medical officer to the Llwynderw Military Convalescent Hospital, of which his wife was the matron. During the 1914-18 war he had served as a captain, R.A.M.C., in Mesopotamia. Dr. Marks worked at high pressure during the whole of his career, and devoted a large part of his life to the administrative side of medicine. He was never happier than when attending a meeting of his fellow practitioners. He died, as he would have wished, in harness. He leaves a widow and a son and daughter, both married.—W. H. T.

Dr. JAMES JOHN GALBRAITH died suddenly at Dingwall on Feb. 1 at the age of 71. He came from an old Highland family and was educated at Blair Lodge, Polmont. As an undergraduate at Edinburgh University he was one of the outstanding students of his year, and he graduated with honours in 1899. For some time he worked under Professor E. Sharpey-Schafer as Crichton Research Scholar in Physiology, and it was probably then that he decided to specialize in the study of tuberculosis, to the elimination of which in the Highlands he was to devote the better part of a lifetime. Before returning to his home county he first held appointments at the Royal Victoria Hospital, Edinburgh, and was later medical superintendent at the Ochil Hills Sanatorium. During this period he was one of the band of pioneers led by the late Sir Robert Philip, and it was common knowledge that he was held in very high esteem by his chief in their crusade against tuberculosis. If he had so desired Dr. Galbraith could probably have remained at Edinburgh and pursued an academic career, but his longing to be of service in his own part of the country was a deciding factor. In 1909 he started to practise at Dingwall, and in 1920 the opportunity to enter the public health service arose, and he became tuberculosis officer to the county of Ross and Cromarty. In 1931 he succeeded Dr. W. Maclean as M.O.H., an appointment which he held until his retirement in 1939. Public health in Ross-shire owes a great debt to those two men. They not only were eminently competent but possessed the personal qualities which enabled them to overcome difficulties which would have been insuperable to lesser men. Their fight against superstition and prejudice was just as exacting as the struggle against more tangible problems. Apart from his profession Dr. Galbraith had a wide range of interests, and was a scholar in the true sense of the word. He was recognized as one of the foremost authorities on Celtic culture in the country. His prolific writings included monographs on sculptured stones, Highland music, and clan history. In 1938 he was elected a chieftain of the Gaelic Society of Inverness, and in 1939 was made its chief. He was a staunch supporter of youth, and at the time of his death he was president of both the Ross-Sutherland Rugby F.C. and the Ross County Cricket Club. Dr. Galbraith commanded great respect for his wide culture, practical knowledge, and enthusiasm for life. He was revered all over the Highlands, and Scotland is the poorer by his death.—R. P.

Dr. WILLIAM GEORGE HARNETT died suddenly at his home at Hadley, Barnet, at the age of 68 on Feb. 9. The son of Dr. W. J. Harnett, he graduated at Dublin in 1905, and after house appointments at Southampton, the Royal Western Ophthalmic Hospital, and the City of London Hospital for Diseases of the Chest he joined his father in practice in Barnet. He served in the R.A.M.C. in the 1914-18 war in France and Salonika, and he was taken prisoner in the spring of 1918. For thirty-eight years he had been the medical superintendent of the Barnet Isolation Hospital, retiring only last month when the hospital became a maternity unit. For thirty years he had been the divisional surgeon to the Metropolitan Police at Barnet, an office which his father had held for the previous twenty-six years. Dr. Harnett had been for several years chairman of the medical staff of the Victoria Hospital, Barnet, and he served on the general committee of the same hospital. He gave many years of service as secretary of the local medical and panel committee for Hertfordshire. He had been a justice of the peace for Hertfordshire and Middlesex for the last three years. The Barnet Division of the B.M.A. had elected him chairman on more than one occasion, and he was a past-president of the Hertfordshire Branch of the B.M.A. During the recent war Dr. Harnett was deputy chairman of a recruiting board and chairman of the Barnet Local Medical War Committee. He had also been a member of the former Hertfordshire Public Assistance Committee and vice-chairman of the board of governors of the Queen Elizabeth's School. In all his activities he gave great service to the public and his colleagues. He had a keen sense of humour and a ready wit, and he was a good after-dinner speaker. He is survived by his widow and one daughter, to both of whom the sympathy of his fellow practitioners will be extended.—N. G. T.

Dr. A. F. Perigal writes: The sudden death of my brother-in-law, George Harnett, the oldest practitioner in Barnet, removes an outstanding personality who will be greatly missed, for though aware of his disability he was ever plucky and cheerful and never allowed it to encroach upon his strict sense of duty. I shall always have pleasant memories of his able and ready help in years gone by when in practice in New Barnet. He was a very genial and good fellow.

Dr. LEANDER JOSEPH JOHN ORPEN died at his home at Alice, Cape Province, South Africa, on Feb. 12, at the age of 72, after a long illness. Born in South Africa, he was educated at Cheltenham and at Keble College, Oxford. He graduated B.M., B.Ch. from Guy's Hospital in 1906, and he took the D.P.H. in 1920. Most of his working life was spent in the Southern Rhodesia Medical Service, and he finally became director of the Pasteur Institute and the public health laboratory at Salisbury. Dr. Orpen was a man of untiring energy, the present efficiency of the services he directed in Rhodesia gely due to his work. He made many contributions to the standing of the aetiology of the dysenteries, and was the to recognize the presence of the brucellosis in Rhodesia. e retired to East London in 1932, but on the outbreak of war he took over the training of medical aides at the South African Native College at Fort Hare. It was due to his foresight and hard work that the present degree of B.Sc.(Hygiene) of the University of South Africa was created to meet the increasing demands for trained African personnel. He retired from active work only last year and was not spared long to enjoy his rest. Dr. Orpen will be remembered by all who came in contact with him for his keen mind and for the high standards he demanded both in his own work and in that of his subordinates and students. Always kindly and approachable, he had no lack of friends, either among his colleagues or among the Africans, to whose welfare he devoted so much of his life.—W. N. T.

Dr. Alexander McConnell Erskine, who was in general practice and also medical officer of health for Goole for forty-four years, graduated not at Belfast, as stated in our notice (Feb. 26, p. 370), but at Dublin. He was a student at the then unchartered Queen's College, Belfast, and subsequently he took the London D.P.H.

Surgeon Rear-Admiral K. A. MacKenzie and Surgeon Captain C. N. Ratcliffe, R.N., have been appointed Honorary Physicians to the King in succession to Surgeon-General Sir Henry E. Y. White, K.C.V.O., O.B.E., and Surgeon-Admiral Sir Henry St. C. Colson, K.C.B., C.B.E., R.N., re-Vice-Admiral, who have been placed on the Retired List.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

H. W. A. Baron has been approved at the examination for the M.Chir. degree.

UNIVERSITY OF LONDON

Professor J. D. Boyd, M.D., has been appointed a representative of the University on the governing body of St. George's Hospital.

The recognition of the British Postgraduate Medical Federation as a school of the University has been extended in respect of its facilities at the Institute of Laryngology and Otology for a period of five years in the first instance, from Oct. 1, 1948.

The following have been recognized as teachers of the University in the subjects indicated in parentheses: *Royal Free Hospital School of Medicine*: Dr. Doris Manning-Baker and Dr. Alice M. C. Macpherson (Medicine); Mrs. Muriel E. Sacks (née Landau), F.R.C.S. (Surgery); Miss Beatrice E. Turner, F.R.C.S. (Obstetrics and Gynaecology).

Leicester Royal Infirmary and the North Staffordshire Royal Infirmary, Stoke-on-Trent, have been recognized for the purposes of the Diploma in Clinical Pathology for external students for a period of five years, from September, 1948.

The 1948 Paul Philip Reitlinger Prize of the value of £30 has been awarded to Dr. Sheila Mary Chitty (née Howarth) for her essay on circulatory effects of acute changes in the venous filling pressure of the heart.

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY (DIAGNOSIS): Part I.—N. N. Blaxland, D. J. Chapman, H. Clain, D. Cockcroft, W. E. Craddock, MacK. M. Craig, F. M. Cryer, D. A. N. Drury, I. O. Fairman, F. E. Fraser, K. E. Hodge, F. H. Howarth, K. S. Huque, A. W. R. Jenkins, R. P. C. MacDonald, E. V. M. Medill, D. F. Reynolds, M. G. Scott, W. H. Smith, R. F. Stubbs, W. R. R. Thursfield, C. D. Wilson-Sharp.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council held on Feb. 18, with Dr. Edward Bramley, Pro-chancellor, in the chair, the following appointments were made: *Senior Lecturer in Physiology*, Q. H. Gibson, M.D., Ph.D. *Honorary Lecturer in Child Health*, R. R. Gordon, M.D., M.R.C.P., D.C.H., D.R.C.O.G. *Assistant Medical Officer to the Student Health Service of the University and to the Nursing Staff Health Service of the United Sheffield Hospitals*, H. R. Worth, M.B., Ch.B.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow held on Jan. 10, with Dr. W. R. Snodgrass, President, in the chair, M. B. Schwartz, M.B., was admitted a Fellow of Faculty *qua* Physician, and W. W. Frank, L.R.C.P.&S.Ed., was admitted a Fellow of Faculty *qua* Surgeon.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College held on Jan. 29, with the President, Sir William Gilliatt, in the chair, Sir Henry Dale, O.M., G.B.E., F.R.C.P., F.R.S., and Professor J. Heyman, of Stockholm, were elected to the Honorary Fellowship.

The following candidates were elected to the Membership of the College:

G. McG. Barr, A. C. Barthels, D. W. Bentinck, B. Bhattacharya, D. K. Black, Kathleen M. Bower, G. C. Brentnall, Muriel Brighton, C. H. Brown, D. P. Cocks, H. J. A. Conte-Mendoza, E. Cope, F. A. L. da Cunha, F. B. Davidson, J. Del, F. Denny, N. S. Devi, C. J. Dewhurst, Kathleen A. D. Drury, J. G. Dumoulin, J. M. Duncan, L. T. El-Badri, B. H. Ellis, H. R. England, I. H. Faris, B. J. Frankenberg, J. S. Fraser, W. K. Frewen, G. B. Gibson, L. S. Glass, Cecilie Greig, E. J. Holloway, C. G. Irwin, W. H. Laird, R. G. Law, L. E. Lotimer, R. L. Lunt, J. C. MacCarroll, J. A. McGhie, J. F. McInerney, R. M. McIntosh, I. D. Macintyre, A. A. McKirdy, A. T. McNeil, J. H. Malony, S. M. Medicine, G. Mitchell, J. E. E. Morgan, N. F. Morris, C. Mukherjee, N. Noble, E. I. Ostry, A. F. Pearson, H. E. Pellew, D. A. Ranasinghe, B. C. M. Reed, W. A. Robson, E. S. Rogers, J. K. Russell, C. R. Sluming, D. F. Smith, Z. H. Y. Sobani, D. B. Stewart, A. S. Subramani, J. Suchet, Eleanor Tennant, Mary E. Tighe, Mary U. Wilkin, E. O. Williams, E. G. Zacks.

The following candidates from Australia were elected to the Membership of the College:

J. M. Buchanan, S. E. Craig, H. G. Furnell, L. W. Gall, G. T. H. Harris, J. A. Love, H. A. McCredie, H. K. Porter, J. S. Reid, R. B. C. Stevenson, B. M. Sutherland.

The following from New Zealand were awarded the Diploma in Obstetrics:

K. Brasted, A. L. Bryant, F. L. Clark, E. N. S. D'Arcy, E. M. Elder, R. C. Gordon, G. H. Green, R. H. T. Holmden, B. Kahlenberg, M. D. Matich, F. A. H. Neate, K. L. Park, Irene G. Rhodes, H. A. A. Stevely, W. H. C. Teppell.

Medical Notes in Parliament

MILK BILL

Dr. EDITH SUMMERSKILL on Feb. 21 moved the second reading of the Milk (Special Designations) Bill, which had a ready passage through the House of Lords. She said this Bill would have the effect of reducing the incidence of tuberculosis. The first milk regulations had been introduced under the Milk and Dairies (Amendment) Act in 1922. Further regulations were introduced in 1936, but there had been a setback in 1938 when a Bill for establishing areas in which non-designated milk must be pasteurized before sale could not be carried through. In 1943 the Government had issued a White Paper setting out the measures which they proposed to take to ensure that the milk of the country should be of a high quality. Since that time steady progress had been made in clearing up the dairy herds, and since 1944 the number of attested herds had been doubled. This comprised something like 16% of the cattle in the country, but the eradication of animals infected with tuberculosis would take many years.

Eradication must be gradual, and it followed that considerable quantities of non-designated milk would be produced in the years to come. In the interests of the public it was necessary that this milk should be pasteurized before it was sold. Opinion among responsible medical people and health authorities was strongly in favour of pasteurization. A recent estimate by Professor G. S. Wilson put the number of deaths which could be attributed to milk infected by the tubercle bacillus at about 1,500 annually. Many thousands more were crippled. The proportion of deaths was ten times greater in rural areas, where more milk was drunk raw, than in London. The Cattle Diseases Committee estimated that about 40% of dairy cows in this country would react to the tuberculin test and that about 0.5% of milch cows excreted active tubercle in their milk. There were other diseases which the Ministry was anxious to eradicate, and for these also pasteurization was essential. Contagious abortion and mastitis were common, and probably 20% of the cows were infected with the former. Of these, 2% excreted in their milk organisms which in human beings gave rise to undulant fever. The responsibility of the Government in this matter was even greater by reason of the encouragement given to the drinking of milk in schools and through welfare schemes.

The pasteurization of milk if carried out efficiently under proper conditions destroyed all pathogenic organisms. Provision of increased pasteurization facilities did not mean that the cleaning up of the herds was less urgent. Pasteurization did not make poor milk good, but it made all milk safe. At present some 70% of the milk sold for liquid consumption in this country was subject to heat treatment. Professor Wilson, make safe by pasteurization the 30% of milk in this country said pasteurization had practically no effect on the nutritional value of milk.

Dr. Summerskill explained that the Bill, in areas to be specified by the Minister of Food, limited the retail sale of milk to those classes of milk which were sold under a special designation. The restrictions also applied to the supply of milk under the Welfare Foods (Milk) Scheme and the milk in schools scheme, and to the sale or supply of milk to catering establishments, hotels, restaurants, institutions, and schools.

Designations

The approved specially designated milk would be T.T. (certified) milk, a designation which might be changed to T.T. (farm-bottled), T.T. milk, and accredited milk derived from a single herd. By insisting that accredited milk should come only from one herd it would be possible to trace any infected milk. There would in England and Wales be pasteurized milk and sterilized milk. In Scotland there would be certified milk, T.T. milk, standard milk derived from a single herd, pasteurized milk, and sterilized milk. Descriptions of these milks would be set out in the regulations. They were not included in the Bill because it was easier to change regulations than to bring in an amending Bill. Recognition of accredited milk and standard milk and specially designated milks would be restricted to a period of five years from the commencement of the Act. These milks did not reach the standard of safety now expected, but farmers who produced them should be given a reasonable time to grade up their herds to T.T. standard.

Before making orders applying the restrictions to specified areas the Minister would consult with representative bodies in those areas. The statutory instrument would be laid before Parliament forty days before an order was made. The Minister would have power to suspend an order when, for instance, a pasteurization plant broke down. The policy would in the

first place be applied to large urban areas and then extended to rural areas. Before an area was specified a survey would be made of pasteurization facilities available. When they did not suffice for pasteurization of all raw milk sold in the area, producer-retailers of non-designated raw milk would be encouraged to upgrade their milk to T.T. standard or arrange for it to be pasteurized. The first area would probably be specified in a year or eighteen months and the scheme might apply to the country as a whole in five or ten years. The Minister would himself have power to operate heat treatment plant or to arrange for local authorities or other persons to provide plant in any area where facilities were insufficient.

When restrictions imposed by the Bill were in operation revocation of a licence held by a retail distributor in a specified area would mean the closing of his business because he would be unable to sell raw milk. The Bill provided that a warning notice should be given for a first breach of the conditions, and the vendor should be the subject of proceedings only when guilty of a second offence within twelve months.

Mr. HOPKIN MORRIS said the proportion of clean herds in Scotland was about 35%, in Wales about 27%, and in England only about 10%. In Cardiganshire T.T. herds had been brought up to 85%, in Carmarthen to 69%, and in Pembrokeshire to 45%, but the best figure he knew of for an English county was about 27%. He pointed out that under the Bill all milk would have to be bottled where it was treated. Why should the small retailer be able to bottle T.T. milk in safety and yet not be allowed to bottle this other milk?

Mr. SOMERVILLE HASTINGS said the most distressing cases he had seen in a long professional life were those of tuberculous meningitis in children; 50% of such cases were due to the bovine variety of tubercle bacillus and presumably due to drinking milk. Pasteurization could be depended on to give a pure milk supply; 98% of the milk in London was pasteurized, and tubercle bacilli had not been found in it for the last four years.

In Toronto, where milk had been compulsorily pasteurized since 1915, they had not had a single case in ten years of any form of bovine tuberculosis, although 26% of the milk entering that city contained the germs of it. There were other diseases carried by milk. Many epidemics were due to infection of milk by those who handled it. Between 1912 and 1937 there were in Britain 115 epidemics of dysentery, scarlet fever, typhoid, and septic sore throat, involving 14,000 people, which were found to be due to milk. Only by pasteurization could the spread of such diseases through milk be eliminated with certainty. On objections to pasteurization he quoted Professor A. D. Kay, of the National Institute for Research on Dairying, who had written that ordinary controlled commercial pasteurization caused practically no nutritional change in milk.

Mr. STRACHEY, dealing with points made by Dr. HADEN GUEST and others, said that before looking to the question of whether T.T. milk should be pasteurized the Ministry should make safe by pasteurization the 30% of milk in this country which it could not claim to be safe. That was the purpose of the Bill. The effect of pasteurization on milk was known. It reduced the vitamin C content slightly; that was the only ill-effect of pasteurization. The Government was devoting a substantial share of stainless steel, aluminium, and other materials to the provision of extra equipment for the agricultural industry. The point whether those who handled milk should not be medically examined might be considered during the committee stage of the Bill. The Government supported it in principle. Local authorities under the Bill would not have power to enforce cleanliness on farms. Responsibility for important measures of enforcement was granted under the Food and Drugs (Milk and Dairies) Act, 1944. In the autumn of this year responsibility for enforcement of cleanliness on farms would pass from the local authorities to the Ministry of Agriculture. He admitted that the Bill hastened slowly and that five years was a long time in which to tolerate the consequences of the sale of unsafe milk. The Bill at all events made a start with ridding the country of what had been in the nature of a national disgrace.

The Bill was then read a second time.

Foreign Visitors

Asked how he proposed to compensate the State doctors for the services they rendered to foreigners who contributed nothing to the National Health Service, Mr. BEVAN replied on Feb. 17 that separate figures were not available, but the population statistics on which the remuneration of general practitioners was calculated included foreign visitors who had been in the country for 28 days. A doctor attending a foreign visitor received the usual fee for a temporary resident. Figures were not available to show how many foreign visitors had received attention under the National Health Service.

Amending Bill This Session

Mr. GEORGE JEGER asked Mr. Bevan on Feb. 17 whether he could now give any indication when he intended introducing legislation to implement the findings of the Slade Committee on medical partnerships.

Mr. BEVAN said that legislation would be introduced this session.

Remuneration of Consultants

On Feb. 17 Dr. BARNETT STROSS asked when Mr. Bevan would be able to submit his proposals on the terms and conditions of service of hospital staffs; whether he knew that the delay caused hardship to ex-Service full-time consultants, whose remuneration was well below that of many other consultants who were employed part-time on a sessional basis; and whether, while discussions took place, he would consider making a retrospective payment of an interim nature.

Mr. BEVAN could not say when the proposals would be available for publication. He was doing all he could to complete discussions with the profession's representatives. Meanwhile he could not contemplate any additional retrospective payment.

Deaths from Smallpox.—Asked how many deaths from smallpox occurred in England and Wales in 1947 and 1948, and what were the ages, Mr. BEVAN furnished on Feb. 17 these particulars: 15 in 1947 and none in 1948; the ages were—7, 27, 49, 69, 70 (2), 72, 75 (3), 76, 78, 79 (2), and 86.

EPIDEMIOLOGICAL NOTES

Influenza

The number of deaths in the great towns in the week ended Feb. 19 was 158, compared with 94 in the previous week; 87 of these deaths were in London and the south-east. The majority of the deaths (135) occurred in persons over 55, so that there is no sign of any relative increase in the number of deaths in young people. There has been some increase in incidence in London and the south-east, but, generally speaking, the disease seems to be of a mild type.

Discussion of Table

In *England and Wales* there were increases in the notifications of measles 4,641, acute pneumonia 123, scarlet fever 45, and diphtheria 32. There was a decrease in the incidence of whooping-cough 157.

For the third consecutive week there has been a large increase in the notifications of measles. During the week under review the largest rises were: Staffordshire 548, Middlesex 415, Essex 398, Lancashire 373, Southampton 341, Yorkshire West Riding 321, London 313, Glamorganshire 250, Cheshire 217, Warwickshire 141, Somerset 138, Kent 132, Hertfordshire 119, and Shropshire 102. The only important exception to this rising trend of measles was a decrease of 70 in Lancashire.

The rise in the incidence of diphtheria was due to the experience of Lancashire, where the cases rose from 19 to 35; of these 35 cases 17 were notified in Liverpool C.B. The largest decreases in the notifications of whooping-cough were Yorkshire West Riding 37, London 36, and Lancashire 31.

The chief centres of dysentery were Lancashire 23 (Blackburn C.B. 7 and Liverpool C.B. 7) and London 16 (Islington 8). Two cases of acute poliomyelitis were notified in London, Wiltshire, and Warwickshire.

In *Scotland* there were increases in the notifications of scarlet fever 35 and whooping-cough 54 and decreases in the incidence of acute primary pneumonia 35 and measles 31. A fall of 69 in the notifications of acute primary pneumonia occurred in the western area, but in the combined north-eastern and eastern area a rise of 32 was reported.

In *Eire* infectious diseases were more prevalent during the week, and increases were reported in the incidence of whooping-cough 30, measles 23, primary pneumonia 15, and scarlet fever 8; the only decrease was in the notifications of diarrhoea and enteritis 21. These changes were mainly due to the experience of Dublin C.B.

In *Northern Ireland* decreases were recorded in the notifications of measles 34, scarlet fever 13, and whooping-cough 13.

Week Ending February 19

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,333, whooping-cough 3,027, diphtheria 112, measles 19,502, acute pneumonia 1,469, cerebrospinal fever 37, acute poliomyelitis 19, dysentery 104, paratyphoid 9, and typhoid 3.

No. 6

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Feb. 12.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included) (b) London (administrative county) (c) Scotland. (d) Eire. (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London) (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

Alert... AND FREE FROM PAIN

When the burden of pain proves too heavy, mental outlook becomes distorted. In such a case the drug of choice is 'Physeptone' which gives satisfactory analgesia while leaving the mind clear.

'PHYSEPTONE'

21-2-DIMETHYLAMINO-4,4-DIPHENYLHEPTANE-5-ONE HYDROCHLORIDE

THE ESTABLISHED ANALGESIC

BURROUGHSWELLCOMBE & CO.
(The Wellcome Foundation Ltd.) LONDON

A Protective Measure for the Epileptic

For this patient, the doctor prescribed Spencer as a means of lessening the danger of spinal injury during seizures.

The patient, age 26, is a victim of cerebral palsy of a mixed spastic and tension athetoid type, quadriplegic in distribution and associated with a rather severe convulsive state. Deformities include equinus on the right, severe pronation of the right forearm, and a mild curvature of the spine. Back pain has responded satisfactorily to the support provided by SPENCER.

Spencer Supports are therapeutically effective because: Each Spencer Support is *individually designed, cut and made* for each individual patient.

Benzocain. B.P. - - - 5.0%

Kaylene-ol in Upper Respiratory Infections

The common cold, sinusitis, tonsillitis, and other inflammatory conditions of the nose and throat lead inevitably to the swallowing of infected exudates.

The digestive tract, deranged by toxins, bacteria and fever, is ill-prepared to receive them.

The routine use of Kaylene-ol on these occasions does much to normalise the gastric and intestinal functions, and to nullify the harmful effects of noxious discharges.

DOSAGE: 1 to 4 drachms of KAYLENE-OL night and morning, or preferably 20 minutes before each meal.

Samples and literature on request

Medical News

COMING EVENTS

Rations and Allowances for Diabetics

The Ministry of Food states that, in lieu of their sugar ration and the ordinary allowance of cheese, sufferers from diabetes or illness should receive: Meat: two extra rations a week, cheese 10 oz (340 g) a week, fats 12 oz extra butter/margarine, which can be taken up with the ordinary rations (a) in odd-numbered ration weeks—12 oz butter, 8 oz (226 g) margarine, (b) in even-numbered ration weeks—6 oz (170 g) butter, 12 oz margarine. The amount of cooking fat available to diabetics is equal to that available to the ordinary consumer. Milk (if prescribed): 7 pints (4 litres) a week.

Order of St. John

The following promotions, and appointments to, the Veritable Order of the Hospital of St. John of Jerusalem have been announced: As Commander (Brother), Lieutenant-General Neil Cantle, C.B., M.C., F.R.C.S. As Officers (Brothers), Drs W. E. Ruttle and N. S. B. Winter. As Associate Serving Brothers, Drs M. N. Oster, J. V. Reuben, J. M. Raphael and J. Cohen, T.D.

Garaging of Cars at B.M.A. House

The large basement garage under the North Wing is now available for the parking of cars between the hours of 9 a.m. and 6 p.m. and 9 a.m. and 1 p.m. on Saturdays. This service is free to members of the Association. The garage is under the management of Messrs G. J. Shaffer, who have installed equipment, which includes greasing and oiling bays, to enable them to provide a valeting service for members' cars at approved charges. Petrol can be obtained in the garage yard. A representative of Messrs Shaffer will attend at their office on the ground floor, Tavistock House South (opposite the B.M.A. Inquiry Room), to assist and advise members. Cars will approach the garage through the main entrance in Tavistock Square and leave by the exit in Burton Street. The centre courtyard at B.M.A. House will be closed to all motor traffic.

Sir Henry Newland Resigns

Sir Henry Newland has announced his resignation as Federal President of the British Medical Association in Australia, reports *The Times* of Feb. 24. He is said to have made the decision when the Federal Government broke off negotiations on the free medicine plan, and to have denied that his action was in any way due to dissension between himself and the Federal Council.

Rheumatism Scheme

The Leeds Regional Hospital Board states that the proposed scheme for the development of a diagnostic treatment and research centre at Harrogate submitted to the Minister by the Board (*Journal*, Jan. 29, p. 188) is of necessity a long-term project. The development of such a centre is therefore likely to be undertaken in very gradual stages. However, the Minister has approved the first stage, which is the purchase by the Board of the White Hart Hotel for £27,500. It is proposed to use accommodation acquired in this way for ambulant patients not needing complete or highly specialized nursing care and attention.

Payment of Sickness Benefit

The Ministry of National Insurance states that payment of sickness benefit may be delayed or lost if people who are sick fail to notify the local National Insurance Office of their incapacity within three days. If for any reason a medical certificate cannot be obtained within the first three days of sickness, a note giving the full name, address, and National Insurance number should be sent by the claimant or, if he cannot send it, by someone on his behalf to the local National Insurance Office informing them of the incapacity. This should be followed up by the first medical certificate as soon as possible and in any case within ten days.

Medical Films

The Swedish Embassy has lent the 16-mm film, "Morning of Life," to the Tavistock Clinic. It deals with the emerging faculties of the infant. The film is silent, runs for about 25 minutes, and has easily understandable Swedish subtitles (a translation is being prepared). It is available, for non-commercial showing only, to medical organizations. Particulars may be obtained from the Tavistock Clinic, 2, Beaumont Street, London, W.1. The Danish Embassy has available a 16-mm copy of Dr. Jarl Wagner Smith's film, "Determination of Intelligence on Rats by Means of the Maze Method." It is a 17-minute silent film with subtitles in English.

Family Planning Association

The Family Planning Association has arranged a medical conference to be held at Guthrie House, 3, Cadogan Gate, Sloane Street, London, S.W., on Saturday, March 12, at 10.30 a.m.

Mental Health Conference

The National Association for Mental Health will hold a Conference on Mental Health at Seymour Hall, Seymour Place, London, W.1, on March 17-18. Sir Wilson Jameson will give the introductory address, medical men taking part include Professor D. R. MacCalman and Professor J. C. Spence. Information may be obtained from the Conference Secretary, 39, Queen Anne Street, London, W.1.

Association of Army Psychiatrists

The sixth reunion of Army psychiatrists will take place at Slater's Restaurant, 18-24, Kensington High Street, London, W., on Saturday, March 19, from 7.30 p.m. to 10.30 p.m. Particulars may be obtained from the honorary secretary, Dr J. C. Penton, The Old Farm House, 1, Gatehill Road, Northwood, Middlesex.

Congress of Climatologists

The first Congress International de Climatisme Social will be held at Villard-de-Lans on March 25-27 under the presidency of Professor Debre. Particulars may be obtained from the secretary, Dr Terrel, Villard-de-Lans, Isere, France. The town has been chosen on account of its unusual climatic qualities and the comparative freedom from tuberculosis there. The chief work of the congress will be to discuss social climatology in France and other countries. It will be in five parts: (1) Reports on general climatic, clinical, and social aspects of medicine will be given by Professors Delore, Bert Rohmer, and Caussade, and others. (2) The problems of social climatology and tuberculosis will be discussed by Professors E. Bernard and Dufourt, and others. (3) Climatology apart from tuberculosis will be discussed by Professors Mourquand, Jeune, and Chaptal, and others. Professors Justin Besançon and C. Debray will give a report on climatology in relation to non-tuberculous adults. Professor Merklen and Dr. Auyaleu will speak on organization and hygiene. (4) Schools, camps, and hygiene administration will be discussed. (5) Contributions on climatology in foreign countries, speakers include Dr. Dermot MacCarthy and others. There will also be an exhibition on education and the care of children.

Rheumatic Diseases

A concentrated week-end course on the rheumatic diseases will be held at the Rheumatism Unit, St. Stephen's Hospital (London County Council), Fulham Road, S.W., on March 26 and 27. The inaugural lecture will be given by Professor Bruce Perry, and other lecturers include Dr. Francis Bach, Dr. Grace Batten, Dr. Philip Ellman, Mr. Timbrell-Fisher, Dr. Blake Patchard, Dr. David Shaw, Dr. A. G. Signy, and Dr. Margaret Snelling.

Bristol Medical Reunion Dinner

The Bristol Medical Reunion Dinner will be held in Bristol on Saturday, April 30. Particulars may be obtained from Dr. Richard Clarke, Harley Lodge, Clifton Down, Clifton, Bristol, 8.

American Society of Medical Technologists

The American Society of Medical Technologists will hold its seventeenth annual convention on June 20-23 at the Hotel Roanoke, in Roanoke, Virginia. Further information may be obtained from Miss Ida L. Reilly, M.T. (A.S.C.P.), Roanoke Hospital Association, Roanoke, Virginia, U.S.A., who is the convention chairman.

APPOINTMENTS

Dr. H. H. Cavendish Fuller has been appointed Chief Medical Officer to the Railway Executive, British Railways.

Dr. Fuller graduated at Edinburgh University in 1912, and proceeded M.D. in 1931. He has had experience of general practice and was medical officer in charge of Malvern College from 1917 to 1930. During that period his appointments included that of medical officer to the Ministry of Pensions in the Malvern area. He was appointed Chief Medical Officer to the G.W.R. in 1930, and in 1931. In March, 1948, he was appointed Medical Officer to the G.W.R.

FULHAM HOSPITAL, St. Dunstan's Road, Hammersmith, W.—Senior Medical Registrar, D. Barmitt, M.B., B.S., M.R.C.P. Senior Surgical Registrar, J. L. Temple, F.R.C.S. Part-time Senior Registrar (Ear, Nose, and Throat), J. L. Wakelin, M.R.C.S., L.R.C.P. Part-time Senior Registrar (Gynaecological), S. A. Boyd, M.B., Ch.B., M.R.C.O.G. Junior Medical Registrar, A. W. N. Oakley, M.B., B.Ch. Junior Surgical Registrar, M. L. Graeme, M.B., B.Ch. Casualty Registrar, J. A. Vye, M.B., B.S. MANDESON, W. G., M.B., Ch.B., Deputy Resident Physician (Fever), Ham Green Infectious Disease Hospital and Sanatorium, Bristol. WATERFALL, W. B., F.R.C.S., Surgeon, Prince of Wales's Hospital, Plymouth.

SOCIETIES AND LECTURES

Monday

- HUNTERIAN SOCIETY.—At the Mansion House, London, E.C., March 7, 8.30 p.m. "Personal Experiences," Hunterian Oration by Sir Heneage Ogilvie. (Postponed from Feb. 28.)
- INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-2, Gray's Inn Road, London, W.C.—March 7, 5.15 p.m. "Dermatology as it Concerns the Ear, Nose, and Throat," by Dr. A. C. Roxburgh.
- LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., March 7, 4.45 p.m. "Haem Pigments in Nature," by Professor C. Rimington.
- ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—March 7, 5 p.m. "The Anatomy and Physiology of Bone—Part I." Arnott Demonstration by Dr. F. S. Gorrill.
- MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, London, W.—March 7, 9 p.m. "Richard Bright, Before and After." Second Lettsomian Lecture by Dr. Horace Evans.

Tuesday

- CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 47, Queen's Gate Terrace, London S.W., March 8, 7 for 7.30 p.m. Annual general meeting. Discussion: "Prefrontal Leucotomy," to be opened by Dr. W. McKissock and Dr. D. Curran.
- INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C., March 8, 5 p.m. "The Dermatophytes," by Dr. I. Muende.
- INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-2, Gray's Inn Road, London, W.C., March 8, 9.30 a.m. "Non-operative Treatment of Maxillary Sinusitis," by Mr. Myles L. Formby.
- INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., March 8, 11 a.m. "Yaws, Pinta, and Bejel," by Dr. J. C. Hawksley.
- LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, London, W.C., March 8, 5.15 p.m. "Chemoceptor Activity," by Dr. A. Schweitzer.
- MEDICAL SOCIETY OF LONDON.—At Claridge's Hotel, Brook Street, London, W., March 8, 7.30 for 7.45 p.m. 169th Anniversary Dinner.

Wednesday

- INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., March 9, 11 a.m. "Clinic Administration," by Dr. W. N. Mascall.
- ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—March 9, 5 p.m. "The Anatomy of the Tongue in its Relation to Surgery." Arnott Demonstration by Mr. P. H. Michiner.
- ROYAL SANITARY INSTITUTE.—At 90, Buckingham Palace Road, London, S.W., March 9, 2.30 p.m. London Sessional Meeting. "The Continuity of the Medical and Social Services in Home and in Hospital." Discussion to be opened by Drs. W. S. Walton and A. B. Williamson.
- SOCIETY OF CHEMICAL INDUSTRY: MICROBIOLOGICAL PANEL OF FOOD GROUP.—At Medical Society of London, 11, Chandos Street, W., March 9, 6.15 p.m. Annual general meeting, 6.30 p.m. "Microbiological Problems in the Production of Pure Water," by Dr. E. Windle Taylor.
- SOCIETY OF PUBLIC ANALYSTS.—At Royal Society, Burlington House, Piccadilly, London, W., March 9, 3.30 p.m. Annual general meeting. Address of the Retiring President, Mr. Lewis Eynon, B.Sc., F.R.I.C.

Thursday

- INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C., March 10, 5 p.m. "Bullous Eruptions," by Dr. L. Forman.
- INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., March 10, 11 a.m. "Prophylaxis in Venereal Disease," by Dr. A. H. Harkness.
- LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Trocadero Restaurant, Piccadilly Circus, London, W., March 10. Annual Dinner and Dance.
- LONDON UNIVERSITY.—At Large Lecture Theatre, St. George's Hospital Medical School, Hyde Park Corner, London, S.W., March 10, 4.30 p.m. Lecture-demonstration: "Neurology."
- LONDON: UNIVERSITY COLLEGE.—At St. Thomas's Hospital Medical School, London, S.E., March 10, 5 p.m. "Ionic Exchange and Electrical Activity in Nerve and Muscle." Special University Lecture by Dr. A. L. Hodgkin.
- ROYAL SOCIETY, Burlington House, London, W.—March 10, 4.30 p.m. Lecture on the Work of the National Institute for Medical Research, by Sir Charles Harington, F.R.S.

Friday

- LONDON CHEST HOSPITAL, Victoria Park, E.—March 11, 5 p.m. "General Anaesthesia for Surgery of the Heart," by Dr. Parry Brown.
- ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—March 11, 8 p.m. Valedictory address by the Senior President.
- ROYAL SANITARY INSTITUTE.—At Municipal Buildings, Southend-on-Sea, March 11, 10.30 a.m. "The Problems Connected with Houseboats as These Concern a Seaside Resort." Symposium by Mr. Archibald Glen, Dr. J. Stevenson Logan, Mr. Reginald A. Drake, and Mr. R. K. Wortley.

SOCIETY OF PUBLIC ANALYSTS: PHYSICAL METHODS GROUP.—At Chemistry Lecture Theatre, Imperial College of Science and Technology, Imperial Institute Road, South Kensington, London, S.W., March 11, 5 p.m. 20th Ordinary Meeting. "Polarographic Analysis." Papers by P. Welford, B.A., A.Inst.P., J. A. Lewis, and J. G. Waller, B.Sc., A.R.I.C.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At Miller Hospital, Greenwich High Road, London, S.E., March 11, 8.30 p.m. Address by Dr. W. R. Heddy, H.M. Coroner for S.E. London.

Saturday

SOUTH EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY.—At Queen Mary's Hospital, Sidcup, Kent, March 12, 10.30 a.m. "B.C.G.," by Dr. F. R. G. Heaf.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

- Brain.—On Feb. 23, 1949, at Chesterfield Nursing Home, Bristol, to Marion, wife of Dr. Russell Brain, of Grantham Road, Kingswood, Bristol, a son.
- Curnock.—On Feb. 19, 1949, at Chingford, to Vera (née Bucknell), wife of Dr. G. H. R. Curnock, a second son—Robert Michael.
- Hare.—On Feb. 18, 1949, at Seabourne Nursing Home, Bournemouth, to Molly (née Bush), wife of Dr. Dennis M. Hare, a daughter.
- Hill.—On Feb. 19, 1949, at Johnstone House, Belfast, to Nancy (née Hinchcliff), wife of William J. C. Hill, M.B., of Portrush, a son.
- Ormsrod.—On Feb. 23, 1949, to Iris, wife of Peter Ormsrod, 61, Calcott Road, N.W., a daughter—Jennifer Anne.
- Skempton.—On Feb. 22, 1949, to Leslie, wife of Ivor P. D. Skempton, M.B., B.S., a third son—Keith.

DEATHS

- Armstrong.—On Feb. 12, 1949, at Ainthorpe House, Danby, Yorks, Cedric Whitfield Armstrong, M.R.C.S., L.R.C.P., aged 63.
- Brock.—On Feb. 16, 1949, at Dunn Street House, Westwell, Kent, George Sandison Brock, M.B.E., M.D., F.R.C.P.Ed., F.R.S.Ed., Commander of the Order of the Crown of Italy (1919), of Greenbanks, St. Saviour, Jersey, C.I., aged 90.
- Brown.—On Feb. 13, 1949, Bessie Brown, M.D., of 29, Ripon Road, Harrogate, aged 44.
- Budd-Budd.—On Feb. 16, 1949, at 15, West Drive, Queen's Park, Brighton, Edward John Budd-Budd, M.R.C.S., L.R.C.P., aged 76.
- Chadburn.—On Feb. 18, 1949, at The Limes, Jacob's Post, Burgess Hill, Sussex, Charles Nugent Chadburn, M.R.C.S., L.R.C.P.
- Coutts.—On Feb. 13, 1949, at Rusland, Spencer Road, Canford Cliffs, Bournemouth, Francis James Henderson Coutts, C.B., M.D., D.P.H., late Senior Medical Officer, Ministry of Health, aged 83.
- Cundell.—On Feb. 18, 1949, at Tadworth, Surrey, Harold Juler Cundell, M.R.C.S., L.R.C.P.
- Davies.—On Feb. 20, 1949, at Hill End Hospital, St. Albans, Thomas Edwin Davies, M.B., Ch.B., late of Oldham Road, Manchester, aged 48.
- De Smidt.—On May 19, 1948, at Nairobi, Kenya, Frank Philip Gilbert de Smidt, M.R.C.S., L.R.C.P., D.P.H., aged 58.
- Dickson.—On Feb. 15, 1949, at Invermac, South Queensferry, George Alexander Dickson, J.P., M.B., C.M.
- Edlin.—On Feb. 23, 1949, at Middlemore House, Levenshulme, Manchester, Herbert Ebenezer Edlin, M.R.C.S., L.R.C.P., aged 86.
- Edwards.—On Feb. 23, 1949, Ivor Charles Edwards, M.D., D.P.H., of 11, The Grove, Isleworth, aged 62.
- Ensor.—On Feb. 10, 1949, Cecil Arthur Ensor, M.R.C.S., L.R.C.P., late of Tisbury, Wilts, aged 75.
- Friend.—Recently, Julius Friend, L.S.A., of Leeds, aged 82.
- Garde.—On Feb. 17, 1949, at Ivycliff, Flushing, Falmouth, Walter Henry Ormonde Garde, F.R.C.S.Ed., Surgeon Captain R.N., retired, aged 78.
- Gilmore.—On Feb. 19, 1949, at 274, Mauldeth Road West, Chorlton-cum-Hardy, Manchester, Eric St. George Gilmore, M.B., Ch.B., aged 54.
- Glasban.—On Feb. 11, 1949, at Dumfriesshire, Alexander Clark Glasban, M.B., Ch.B., of Burnley.
- Greene.—On Feb. 18, 1949, Helen M. Greene, M.D.Brux., of Woods Farm, Chobham, Surrey.
- Hale-White.—On Feb. 26, 1949, at 24, Warnborough Road, Oxford, Sir William Hale-White, K.B.E., M.D., F.R.C.P., aged 91.
- Holmes.—On Feb. 11, 1949, at 2, Staveley Road, Eastbourne, Bernard Willoughby Holmes, M.R.C.S., L.R.C.P.
- Jackson.—On Feb. 20, 1949, Robert William Henry Jackson, M.D., D.P.H., Major R.A.M.C., retired, of Highfield, Caernarvon, North Wales, aged 84.
- Jerram.—On Jan. 21, 1949, in Rhodesia, Ursula Jerram, M.R.C.S., L.R.C.P., D.C.H.
- Johnstone.—On Feb. 22, 1949, at Colinwood, Rhos-on-Sea, Edmund Johnstone, L.S.A., formerly of Clayton, aged 84.
- Klein.—On Feb. 21, 1949, Bruno Klein, M.D., D.P.H., of 60, Approach Road, Cliftonville, Margate, aged 57.
- Laing.—On Feb. 17, 1949, at Lerwick, Arthur Cecil Laing, M.C., Croix de Guerre, M.B., Ch.B., of Levenwick, Shetland.
- McCullagh.—On Feb. 20, 1949, at Queen Elizabeth Hospital, Birmingham, Charles Harold Walker McCullagh, M.D., D.P.H., aged 74.
- Moyes.—On Feb. 3, 1949, at Strathmore, Prospect Road, Portstewart, N. Ireland, Alice Elizabeth May Babington Moyes, M.B., Ch.B.Ed., D.P.M., wife of Dr. John M. Moyes.
- Orpen.—On Feb. 12, 1949, at Alice, Cape Province, South Africa, Leander Joseph John Orpen, B.M., B.Ch., D.P.H., aged 72.
- Paxon.—On Feb. 17, 1949, at 30, St. George's Road, London, N., George Ernest Paxon, M.R.C.S., L.R.C.P., L.D.S.
- Porter.—On Feb. 12, 1949, at 65, Morningside Road, Edinburgh, Frederick Porter, M.B., C.M.Ed.
- Rogerson.—On Feb. 10, 1949, in Baltimore, Cuthbert Harry Rogerson, M.D., F.R.C.P., D.P.M., late Medical Director of the Seton Institute, Baltimore.
- Ruggier.—On Feb. 8, 1949, at 31, Church Avenue, Paula, Malta, Chev. Joseph Gerald Ruggier, M.D., aged 56.
- Somerville.—On Feb. 19, 1949, Edgar Somerville, M.D., F.R.C.S.Ed., of Hartsheath, Newton Abbot, South Devon, formerly of Leek, Staffs., aged 74.
- Tobin.—On Feb. 23, 1949, Joseph Richard Tobin, M.R.C.P.I., formerly of South Australia.
- Wakefield.—On Feb. 23, 1949, at The Gale near Keswick, Cumberland, Arthur William Wakefield, M.D., aged 72.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Tuberculosis in Ex-Servicemen

Q.—Some young men enter the fighting Services apparently fit but come out with pulmonary tuberculosis. Are there any statistics to indicate whether this is "attributable to military service"?

A.—It is not possible to supply the facts requested; the statistics mentioned are not given in the last report of the Chief Medical Officer of the Ministry of Health for 1939-45. In any event, such figures for the fighting Services could not be compared directly with those for similar age groups in the general population. The men in the Services are selected by a medical examination, often including radiography of the chest, and they have a similar examination on discharge. These are bound to reveal some tuberculous lesions which would remain undiscovered in a civilian.

Cases of tuberculosis discovered during or just after a period of military service can be divided into two categories: (1) Those in which the disease is almost certainly attributable. These are comparatively few and include those with a radiologically clear chest on enlistment who have been subjected to definite strain or privation—such as prisoners of war—or who are known to have been living in close contact with cases of open tuberculosis. (2) Those in which there is doubt. It is always difficult to estimate the age of a tuberculous lesion, and if no x-ray film was taken on enlistment (or discharge) it is usually impossible to say that the disease did not develop during the period of service. Even if there is no specific cause to which the disease can be attributed the patient can usually plead aggravation by the physical exertion involved in Army life.

The Ministry of Pensions appears to take a lenient view in such cases, and if there is any doubt the patient is usually awarded a pension. As a result some patients whose disease almost certainly developed after discharge from the Services have been given pensions. This generosity has given rise to singular anomalies—for example, a youth conscripted to work in the mines who develops tuberculosis gets no compensation whatever, even though his work has entailed severe physical strain which undoubtedly aggravated the disease.

Angina Pectoris

Q.—A patient aged 45 suffers from severe precordial pain radiating down the right arm which is precipitated by exercise, by emotional upsets, and even by turning over in bed. The heart appears normal on examination. The pain is eased by glyceryl trinitrate. What is the diagnosis, and can you recommend any treatment?

A.—The diagnosis is almost certainly angina pectoris, and this is probably due to occlusive coronary atherosclerosis. There are three main lines of treatment for these cases. The first is conservative. This consists in limitation of activity and stress of all kinds, light diet, increased rest, and the intelligent use of trinitroglycerin—as is well known. Secondly, if the patient is incapacitated despite this regimen, methyl or propyl thiouracil may be given in initial doses of 0.2 g. thrice daily in order to reduce the oxygen requirement and hence the work of the heart, and also to diminish the sensitivity of the organism to adrenergic stimuli. Thirdly, if thiouracil fails or is not well tolerated, surgical intervention may be considered, bilateral stellate and upper dorsal ganglionectomy being the operation of choice.

Specialist advice should be sought before embarking on thiouracil therapy and before submitting the patient to sympathectomy. The diagnosis of angina pectoris is by no means always easy, and should be established beyond doubt one way or the other in all cases. By far the best test is to obtain an electrocardiogram immediately after effort of sufficient degree to provoke pain or breathlessness and fatigue. Diagnostic

ischaemic depression of the S-T segment in left ventricular leads or their equivalent (usually ventricular lead and standard lead I) is obtained in about 95% of cases. It cannot be too strongly emphasized that in uncomplicated cases of angina pectoris (due to occlusive coronary disease) there are no abnormal physical signs and the resting electrocardiogram is normal.

Antibody Formation

Q.—Where in the body does the power of immunity reside? If in the blood, does severe or repeated haemorrhage or the frequent donation of blood lessen immunity?

A.—Recent work indicates that the lymph nodes may be the principal site of antibody formation. Once the antibody-producing cells have been stimulated to yield a particular antibody the power to continue production seems to be handed on to daughter cells and a non-specific stimulus may encourage increased output. Thus, in horses producing diphtheria antitoxin the withdrawal of blood may stimulate the manufacture of antibody. It is therefore unlikely that haemorrhage or frequent donation of blood will interfere with antibody production. The only risk is that the patient may suffer temporarily from a degree of anaemia which may lower resistance to infection. If haemoglobin estimations are made frequently in a regular blood donor any tendency to anaemia will be detected and can usually be corrected by a course of iron.

Death from Curare

Q.—What would be the immediate effect of a lethal dose of curare given intramuscularly? Would there be any local reaction at the site of puncture, and how long would it be before death occurred? What would be found at necropsy? Could the cause of death, if unsuspected, be established?

A.—The post-mortem findings in such a case would be those of asphyxia, with no features to distinguish it from asphyxia due to other agents—for example, various other alkaloid poisons. It is unlikely that there would be any local reaction at the site of injection, and it is very unlikely that the precise cause of death would be established by post-mortem examination if the possibility of curare having been injected was unknown and unsuspected. The effects of a lethal dose would begin to be apparent very soon after the injection, and would consist of a progressive paralysis of the voluntary muscles of the body, starting in the limbs, then affecting the head and neck, and ending with paralysis of the respiratory muscles—intercostal, diaphragmatic, and abdominal. With a large lethal dose death might occur about ten minutes after the injection.

Adiposity

Q.—(a) What advice should be given to a young man who is developing a protruding abdomen? There is a family tendency to obesity, and recently during several months in bed he put on a lot of weight. Is some sort of support advisable, and if so, which type? What exercises should be recommended?

(b) Could you advise treatment for an active middle-aged male suffering from adiposity of pituitary distribution, the trunk being the only part of the body affected?

A.—(a) When fat is put on by those with a family tendency to obesity, as in other cases, the abdomen is often the region selected, and the condition is not infrequently accompanied by laxity of the intravertebral ligaments and some lordosis, which increases the prominence of the abdomen. A support is advisable only in the most extreme cases, and several firms make suitable belts; but exercises to increase postural tone, in the first case under the supervision of a physiotherapist, may prove of some help.

(b) As indicated in (a) above, it is common for the trunk to be the part affected and for the limbs, or their distal parts, to escape the adiposity. There is no known hormone which directly reduces adiposity, and treatment is therefore based on (1) low-calorie diet; (2) diuretics, such as ammonium chloride and mersalyl, to counteract the water-retention factor; and (3) "dexedrine" (amphetamine sulphate) or digitalis to reduce appetite. Amphetamine is sometimes used as an adjunct to therapy in cases of adiposity, and appears to act centrally (cerebrum or hypothalamus) on the hunger or appetite-control

mechanism. It is effective in man and in dogs in reducing voluntary food intake, and this action is not influenced by extrinsic denervation of the stomach and intestine. Amphetamine also causes an apparent slight increase in metabolism, probably by inducing restlessness, and similarly increases dissipation of energy, but clinical trials indicate that these are not the major factors. The above results were found in dogs—even to the point of complete anorexia—before there was evidence of excitement, mania, atonia, or other signs. No evidence of habit formation was found in normal adipose patients, but in psychopaths addiction and toxic reactions have been recorded. Digitalis is also sometimes used in obesity to decrease appetite, as this drug can produce anorexia, nausea, and vomiting by local action on the gastric mucosa or on the vagal nerve endings. For details of some of the experimental work on amphetamine see Harris, S. C., Ivy, A. C., and Searle, L. M., *J. Amer. med. Ass.*, 1947, 134, 1468.

Retinal Pigmentation

Q.—I have recently examined the fundi of an elderly man who has deep conjunctival staining of both eyes due to prolonged local application of silver preparations. Both fundi show heavy deposits of pigment over the whole visible retina and I should like to know if it is possible for argyrosis to affect the retina, and, if so, whether the condition is unusual. Where in the literature can references be found?

A.—There are no reports of staining of the fundus in argyrosis from local application of silver nitrate to the conjunctival sac. The cornea may be involved in the staining, but it is unlikely that intraocular lesions would occur. The internal administration of silver nitrate can produce extensive silver staining in skin and mucous membrane, and there is one histological report (Riemer, *Arch. Heilk.*, 1875, 16, 296, 385) of the deposition of silver in the sheath of the optic nerve in a patient who had been taking silver by mouth over many years. Toxic effects such as retrobulbar neuritis have also been described. They are summarized in *Die Wirkung von Arzneimitteln und Giften auf das Auge*, by L. Lewin and H. Guillery, 2nd ed., vol. ii, 746 (Berlin, 1913). There is a more recent account by Ramond (*Bull. Acad. Méd., Paris*, 1946, 130, 275). These observations, however, have no relevance to the point raised in this question. If retinal pigmentation that can be more readily ascribed to established causes of pigmentary changes in the fundus can be excluded in this particular patient the case would be worth following up.

Chemotherapy of Acute Otitis Media

Q.—Is it advisable to use any of the sulphonamides or penicillin to treat acute otitis media before discharge appears or is induced? Does the early use of these drugs predispose to later deafness?

A.—In the early stages it seems safe to give sulphonamides or penicillin, but if the drum is red and bulging from infected fluid under tension symptoms may be obscured. In such a case it is wiser to incise the drum first. If spontaneous rupture has occurred, and particularly in cases of recurrent suppuration through a permanent perforation, chemotherapy seems reasonably safe; but dosage must be adequate, and the administration of the drug should be continued for four or five days. Some cases of deafness following sulphonamide treatment have been reported by Simson Hall (*Proc. Roy. Soc. Med.*, 1944, 37, 749), and were presumed to be due to inadequate dosage.

Abdominal Pregnancy

Q.—Abdominal pregnancy at 5½ months has now been discovered in a case in which three months earlier a misdiagnosis of appendicitis was made at the time when rupture of an ectopic pregnancy must have occurred. The mother and foetus are normal. How long should the pregnancy be allowed to continue, and are there any special dangers to guard against?

A.—The general view is that laparotomy should be undertaken as soon as the diagnosis of abdominal pregnancy is made. But operation should be carried out by an expert, for the anatomical relations within the abdomen are likely to be much disturbed and great skill and gentleness are necessary if serious hæmorrhage is to be avoided. Hæmorrhage from the placental

site—which may involve any of the abdominal organs—is, indeed, the great danger, and rare judgment is required to decide how best to deal with the placenta and pregnancy sac. Although occasionally the placenta is so situated that maternal blood vessels leading to it can be easily controlled, usually this is not the case, and it is then best to remove the foetus gently with the least possible disturbance of the sac. The umbilical cord is cut short and the placenta and membranes are left inside the abdomen, the abdomen being closed without drainage.

There may be circumstances—for instance, when it might offer the patient her only chance of a live child—in which delay until the child is viable is justified, but they are rare. This course should be followed only after considering the very serious maternal risk involved, and with the fact in mind that the child frequently becomes misshapen by reason of its faulty attitude and position. The older practice of waiting until the patient has had a spurious labour, the child is dead, and the placental vessels have become thrombosed has gone out of favour.

NOTES AND COMMENTS

Leukoplakia and Kraurosis Vulvae.—Dr. ELIZABETH HUNT (London, W. 1) writes: Mr. Stanley Way (Jan. 22, p. 164) criticizes my statement (Jan. 1, p. 42) that cancer in association with the eruption known to gynaecologists as leukoplakia vulvae or leukoplakic vulvitis originates on the inner surfaces of the vulva. The grounds for his criticism are that he has seen cases in which both the inner and outer surfaces were affected. It is always possible that a tumour may extend outwards from the initial site if untreated in an early stage. Reports of surgeons (Morris, 1882; Butlin, 1901) of cancer with leukoplakia vulvae occurs on the mucous surfaces only, not on skin, support my statement, and Blair Bell (1934) states precisely that cancer has never been observed on the extragenital lesions. The skin eruption described by Bonney under the title leukoplakic vulvitis is identical with a variety of lichen planus known to dermatologists as lichen sclerosus. This eruption may occur at any site and may affect mucous surfaces also. I have been unable to trace any record of cancer arising on skin affected by this eruption. The excision of skin affected by this eruption as a prophylactic measure against cancer is not therefore warranted, and one cannot but hope that few women have experienced the ordeal advocated by Taussig for this purpose—i.e., that every case of leukoplakic vulvitis should be treated by surgical excision of the entire vulva, including the perineal and peri-anal skin if these are involved.

Mr. Stanley Way raises the question of nomenclature. It may be queried whether the substitution of the term "vulvitis" for "dermatitis of the vulva" is justifiable, since it involves labelling an eruption on the perineal and peri-anal skin, or on any other extragenital surface, as "vulvitis." To speak of a leukoplakic dermatitis of the vulva and adjacent surfaces would convey a definite idea and avoid confusion in terminology. The term leukoplakia as applied to skin lesions other than affections of the mucous or muco-cutaneous surfaces occurs only in gynaecological literature. It is an attractive term and popular, for even scabies and warts have been referred to me with this diagnosis. This term was suggested by Schwimmer in 1877 to distinguish whitish lesions on mucous membrane from skin lesions. It is customarily applied to lesions of this nature inside the mouth or on the muco-cutaneous surface of the male genital organ. It would, I believe, make for clarity and greater accuracy in diagnosis if gynaecologists would restrict their use of the term to lesions occurring on the internal surfaces of the vulva.

The Human Touch.—This new play, by J. Lee-Thompson and Dudley Leslie, now running at the Savoy Theatre, is based on the discovery of chloroform anaesthesia by Sir J. Y. Simpson. Though well acted and competently produced, the play itself contains many inaccuracies. Professor James Syme presides over a lunacy board which is convened to certify Dr. Simpson. Simpson, played by Alec Guinness, refers constantly to "chlorry," which is given its full title by Professor Syme when he announces the ruling of the faculty that any practitioner using chloroform will be struck off the *Medical Directory*.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 5 1949

THE SECRETARY REPORTS

THE ASSOCIATION AND LOCAL AUTHORITIES

The dispute between the B.M.A. and the associations of local authorities has implications far beyond the Public Health Service. It may be useful to give its background somewhat fully. The Government is committed to the principle of negotiation through Whitley machinery of the terms and conditions of service of those members of the Public Health Service who are covered by the Act. It is an essential part of this Whitley machinery that if agreement is not reached recourse is had to arbitration. It is further agreed that such negotiations should cover not only those medical officers who, because they are employed by county and county borough councils, are within the ambit of the Act, but other medical officers—e.g., medical officers of boroughs, urban district councils, etc.—as well.

Precise proposals for Whitley Council machinery have been put forward and accepted. It was expected that as soon as possible after the appointed day negotiations for new terms and conditions of service for our colleagues in public health would begin. In practice this meant that negotiations could have begun some four or five months ago. Towards the end of last year the associations of local authorities began to raise difficulties. As far as one can gather, their argument was that for the members of the Public Health Service to be dealt with as part of the profession would mean substantial increases in remuneration for its members. Such increases would in turn lead to increases for other professional officers in local government. Faced with the prospect of such widespread increases they challenged the Whitley proposal itself, preferring, it seems, the old method of hard bargaining between local authorities and representatives of the Public Health Service. They have met the Minister of Health on the point, and we surmise that they got short shrift from him.

In fact, he himself anticipated the position when, in the Standing Committee, he said on June 27, 1946, speaking on the national regulation of the remuneration of health workers, that "No doubt it will influence the whole field of local government, and it is rather desirable that that should be so."

In December last the Public Health Committee of the Association, fully aware of the growing disquiet in the Public Health Service, decided that it was justified in bringing pressure upon the associations of local authorities to conform to the Government's policy and to open negotiations through Whitley machinery without further delay. The Council approved, and it passed the following resolution:

"That the Ministry be informed that if negotiations through approved Whitley machinery have not begun by Feb. 28, 1949, advertisements from local authorities will not be accepted by the *British Medical Journal* unless the salaries offered are in conformity with the Association's own proposals for new scales."

At the time of going to press the associations of local authorities have taken no step to open negotiations, with the result that the Council's recommendation comes into operation. From this week we shall accept for publication in the *British Medical Journal* no advertisements which do not conform to the proposals which the Association has made for the revised remuneration of public health officers. What we are asking and are determined to secure is that the negotiations shall open. Once the associations of local authorities open the negotiations the ban will be withdrawn.

In taking this step we have the co-operation of the *Lancet*, the *Medical Officer*, and *Public Health*. We owe a great deal

to the co-operation of the proprietors of these journals. We are particularly indebted to the *Medical Officer* because of the relatively large loss in advertisement revenue which this paper will temporarily sustain.

Fundamentally, the issue is one of the application of the Spens standards to groups of the profession other than those to which the two Spens Reports specifically relate. Medical officers of local authorities are first and foremost members of the medical profession, and only secondarily members of the local government service. It is our duty to secure that their standards of remuneration are appropriately related to the Spens standards whatever difficulties this may bring in its train. It is probably true that the effects of the Spens Reports will be felt not only throughout the medical profession but throughout the professions generally, and particularly by members of the professions who are in the public service. But this is not necessarily a bad thing. In any case we are justified in using all the pressure at our command to secure that the negotiations are opened through the approved machinery for a section of the profession which is suffering substantial hardship at the present time.

Medical Committees

It will be recalled that in answer to the question put to the Minister on the subject of medical committees in April, 1948, he replied in the following terms (*Journal*, April 17, 1948, p. 742):

"The Minister entirely agrees with the system of medical committees in hospitals. But he could not *compel* medical staffs to set them up (nor would the Association presumably wish him to try!). He has already included in his guidance to regional boards and hospital management committees a declaration of the importance which he attaches to the system and asked that every encouragement and facility should be given to it. He also agrees that in teaching hospitals such committees should be representative of all consultants and specialists on the staff, whether they are teachers or not.

"As to the representation of medical committees on boards of governors or hospital management committees, the Minister follows the Act, which requires the latter bodies to include persons appointed after consultation with the senior medical staff of the hospital or hospitals, and the former bodies to include up to one-fifth of their members nominated by the medical and dental teaching staff. In practice, of course, this means that both bodies will include members of the medical committees, with full membership. Moreover, the Minister certainly thinks that consultation should include consultation with the medical committee, where there is one."

In practice, things have not worked out in every area as the Minister expected. In particular the medical staffs of the hospitals under regional hospital boards have expressed dissatisfaction with the methods followed to secure the appointment to hospital management committees of "persons appointed after consultation with the senior medical and dental staff." The view is gaining ground that the one way of ensuring that medical committees are properly recognized and utilized, both in giving advice and in providing proper representation, is by amendment of the Act. The greatness of the voluntary hospital system owes much to the effective medical committee. In association with the boards of governors of teaching hospitals, the hospital management committees, and the regional boards there should be medical bodies representative of and appointed by the medical staffs concerned. Only in this way can it be ensured that the members of hospital staffs will make their most effective contribution to hospital work and play their proper part in the committees concerned with the appointment of the colleagues with whom they will have to work.

National Health Service

DISTRIBUTION OF FUNDS

Central Practitioners Fund

The Ministry of Health states that the Central Practitioners Fund for the period July 5, 1948, to March 31, 1949, will be determined and distributed as though both the civilian population as a whole and the actual numbers on doctors' lists had been the same throughout the period as the figures determined as at Jan. 1, 1949. The Fund will therefore be an amount equal to 18s. a head for 95% of the estimated civilian population of Great Britain as at Dec. 31, 1948. The resulting sum, less a deduction for mileage payments, will be allocated between England and Wales on the one hand, and Scotland on the other, in proportion to the number of persons on doctors' lists at Jan. 1, 1949, plus one-third of the estimated population not on their lists. The allocation to each executive council will be on the same basis.

Central Mileage Fund

The formula governing the distribution of the Central Mileage Fund has not yet been determined for the National Health Service. Meanwhile the distribution among executive councils for the nine months ending March 31 will be in the same proportions as the Central Mileage Fund was distributed among insurance committees under the N.H.I. Act. Executive councils will then distribute the sums in accordance with the mileage schemes in force under the N.H.I. Act, using for the purpose mileages returned by the doctor.

All payments from these funds must be made not later than March 31.

INFLATION OF LISTS

The General Medical Services Committee has considered the problem of inflated lists and has been informed of one area where the number of persons who had signed on was 102%. The committee is anxious that accurate lists in relation to population should be established in all areas as soon as possible, and has set up a subcommittee to investigate the problem. In the meantime the committee has approved the Ministry's suggestion that the number of persons in an executive council area who had signed on should be taken and one-third of the difference between such number and the established population added, the result giving the basic figure for the computation of the local pool; and that the maximum should be 98%, so that any area which showed a higher figure would be brought down to that level.

PRESCRIPTION OF APPLIANCES

LIST AMENDED

The Minister of Health has decided after consultation with the B.M.A. and the Central National Health Service (Chemist-Contractors) Committee that the types of trusses which may be prescribed on Form E.C.10 should be restricted to the following: femoral, inguinal, scrotal, and umbilical. The articles of elastic hosiery which may be so prescribed should be extended to include: leggings, knee stockings, knee leggings, thigh stockings, thigh leggings, and thigh kneecaps. (The list of appliances that general practitioners may prescribe on Form E.C.10 was given in the *Supplement*, Nov. 13, 1948, p. 172.)

Since all chemists do not measure and fit trusses and elastic hosiery, the Ministry suggests that doctors should not include prescriptions for medicines or other appliances on the same prescription form.

Splints of the nature of an elbow- or knee-cage and the Howard March type of knee splint should be supplied only through the hospital service. In addition, the schedule will be amended to include insufflators, nipple shields, medicated plasters as specified in the Drug Tariff, "stem pessaries," and "fluid ring pessaries"; and to limit inhalers and vaporizers by the proviso "as specified in the Drug Tariff."

Patients requiring renewals of, or repairs to, artificial limbs, invalid tricycles, or wheel-chairs should be asked to communi-

cate with the Chief Regional Officer of the Ministry of Pensions, whose address can be obtained from hospitals, post offices, citizens' advice bureaux, or the local offices of the Ministry of National Insurance.

DELAYED ADMISSION TO HOSPITAL

The Local Medical Committee for the County of London considered at a recent meeting the confidential report of a conference held by representatives of the committee, the Ministry of Health, the Emergency Bed Service, and the Metropolitan Regional Hospital Boards. The committee passed the following resolution:

"That the Committee views with dismay the present unsatisfactory conditions which retard the admission of patients into hospital, and in particular those cases which undoubtedly are acute but with which there is also associated a chronic element, and is deeply concerned by the reports which reach it of many patients who have died whose lives might have been saved had energetic action been taken to secure medical and nursing attention for them at the time when practitioners endeavoured to obtain their admission to hospital."

HOSPITAL ESTIMATES TO BE CUT

The Minister of Health has pointed out to all regional hospital boards and most boards of governors that their estimates of requirements for the year 1949-50 exceed what it is possible to provide, and has asked that they should arrange for a reduction of £9,500,000 from the total sum available for hospital maintenance. It will also be necessary to postpone some capital works which otherwise would have been put in hand. He emphasizes his anxiety that the welfare of the patients should not be affected. Expenditure for this purpose should have priority over any other form of expenditure.

FEE FOR EXAMINING STAFF

A fee not exceeding one guinea is payable for the medical examination of candidates for permanent administrative or clerical appointments under the National Health Service after Jan. 25.

MORE X-RAY FILMS

The Ministry of Health states that the arrangements for ensuring adequate supplies of x-ray films to meet the essential needs of hospitals have been discussed with the Board of Trade. Hospital demands for films have risen steeply since July, 1948, and though the quantity of films distributed in 1948 was 20% greater than in 1947 some shortages have arisen. It is hoped that supplies in 1949 will be at least 25% more than in 1948.

The Ministry believes that this additional provision may not bridge the gap between demand and supply, and emphasizes that all hospitals should be sparing in the use of x-ray films and should refrain from placing orders for more than they require or building up greater stocks than are necessary for normal working.

NO PERMITS FOR RUBBER GLOVES

The Board of Trade announces that the restriction which limited the sale of surgeons' rubber gloves only to those people holding a buying permit ended on Feb. 28. Supplies of these gloves are now sufficient to meet normal demands.

HEARD AT HEADQUARTERS

Test Case

Within the next month or so a test case will be brought on the question of the right of the citizen, while under private medical treatment, to have his prescriptions dispensed within the National Health Service. A patient who was being treated privately was prescribed ephedrine by his doctor, and the prescription was countersigned by a famous consultant. The chemist refused to accept it as an N.H.S. prescription, and the patient is now proceeding in the county court to sue the Minister for the return of 3s. 9d.

Questions Answered

Employing Several Assistants

Q.—Upon the retirement recently of my partner, whose share I purchased, I was, on July 5, the sole proprietor of a large practice requiring at least two full-time assistants in order to meet N.H.S. requirements. I am informed that this is "frowned upon" by the authorities, and I have been advised to replace the present situation with a partnership arrangement. Until my compensation is paid, or an amount on account—and I do not know when this will be—my commitments in the practice will not permit me to offer a partnership of reasonable proportions without seriously impairing my income. Although my partnerships are "with view" I cannot give an exact undertaking as to date, but may be forced to do something by the authorities. By what portions of the N.H.S. Act and under what regulations are bodies entitled to enforce restrictions upon me in respect of this situation, what are these bodies, and what are their powers in this respect? The area is not "closed" so far as I know.

A.—The allocation scheme permits a practitioner employing one or more permanent assistants to increase the number of public patients for whom he is responsible by 2,400 in respect of each assistant. It is true that the employment of multiple assistants is frowned upon, and executive councils have powers to refuse a principal an additional assistant unless it is "with view" or he is contemplating taking his present assistant into partnership. There are no powers, however, to compel you to take your present assistants into partnership. It is assumed that you have made a claim for the immediate payment of compensation or a payment on account.

Notification of Puerperal Pyrexia

Q.—Am I compelled to give further information which is asked for by the county M.O.H. in a case of puerperal pyrexia? This occurred in a private patient within the 21 days, and was notified by me to the M.O.H. on the usual form.

A.—No obligation on the practitioner exists in a case of puerperal pyrexia other than the notification to the County Medical Officer of Health on the appropriate form.

Fee for Anaesthetic

Q.—If a patient on my State list elects to have an operation in a private nursing-home several miles outside my area for which I give the anaesthetic and my partner assists, can I charge a fee?

A.—A fee cannot be charged for the administration of the anaesthetic unless it is itself a specialist service and the doctor is a specialist anaesthetist on the staff of a hospital providing hospital and specialist services. If the nursing-home is outside the doctor's area of practice (as defined in his application for inclusion in the executive council's medical list), the doctor is entitled to be reimbursed for the extra mileage and time spent in travelling.

Travellers Going Abroad

Q.—(1) Can a fee be claimed for the completion of a detailed questionnaire and full physical examination of a child going abroad in the holidays?

(2) Can a fee be claimed for the preventive inoculation against typhoid, cholera, tetanus, and yellow fever in the cases of lecturers or people visiting foreign countries on holiday?

A.—(1) Until the Interdepartmental Committee on Certification has reported a practitioner is obliged to render free of charge only those certificates which appear on the detailed circular issued by the Ministry to local executive councils. The examination you have in mind is a medical report, and when demanded by a patient in respect of a child going abroad in the holidays a fee would be admissible.

(2) At present no fee may be charged for the preventive inoculation against these diseases in respect of one of the practitioner's public patients. Detailed negotiations are at present taking place on remuneration for vaccination and immunization.

SCOTTISH COMMITTEE

At a meeting of the Scottish Committee of the B.M.A. at Edinburgh on Feb. 22 intimation was made that the scale of fees negotiated by the committee with the Crown Office with the approval of Council is now in operation. The fees are those in respect of work carried out by members of the profession on behalf of procurators fiscal. Copies of the scale may be obtained from the Scottish Office of the B.M.A.

The committee considered a proposal for the amalgamation of its Highlands and Islands Subcommittee with the Scottish Rural Practitioners Subcommittee. In support of this it was mentioned that the absorption of the old Highlands and Islands scheme into the National Health Service rendered unnecessary the Highlands and Islands Subcommittee, and that the problems of doctors in those areas and the other rural areas of Scotland were essentially the same. In opposition it was pointed out that there were problems outside the field of general practice affecting the Highlands and Islands area, and that in any case problems would remain which were peculiar to the Highlands and Islands.

After further discussion it was agreed that the *status quo* remain and that the respective committees be asked to explore the possibilities of amalgamation.

It was also reported that at a joint meeting of the Highlands and Islands and Rural Practitioners Subcommittees discussion of the present position in regard to dental treatment in the Highlands and Islands and rural areas of Scotland showed that executive councils were dealing with the problems in different ways. Certain councils are remunerating general practitioners when emergency dental services are given, while others consider such dental services to be included in the terms of service of the general practitioners under contract with them. The joint meeting resolved that until an adequate dental service is available in these areas general practitioners giving emergency dental treatment should be remunerated from the local dental pool in accordance with the Dental Service scale of remuneration. The Scottish Committee decided to remit this resolution to the General Medical Services Subcommittee (Scotland).

On the invitation of the Secretary of State for Scotland six representatives were appointed to discuss with him the provision of health centres and in particular the possibilities of developing one or more forms of group practice in suitable areas.

Dr. Grant referred to the discussion which had taken place in the Insurance Acts Subcommittee (Scotland) and in the General Practice Subcommittee of the Scottish Negotiating Committee on the proposed scheme for the training of assistants in Scotland. These bodies had discussed in detail the scheme drawn up by the Ministry of Health for adoption in England and Wales and had made certain suggestions for modifying that scheme in its application to Scotland. These modifications were in the main accepted. In respect of one modification—namely, the selection of "trainer" practitioners by regional selection committees—the Secretary of State had not accepted the proposal that the appointment of general practitioner members of the regional committees should be left in the hands of the local medical committees in the regions, but had retained the right of appointment from nominations made by the individual committees.

The committee endorsed the action taken in respect of the application of the training scheme to Scotland but thought that the question of the method of appointment of general practitioner representatives on the regional selection committees should be reopened with the Department of Health for Scotland with a view to securing that the local medical committees should have the actual power of appointment.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar
Non-Country Borough Councils.—Dartford, WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

HEALTH ADVISORY COMMITTEES

APPOINTMENTS BY MR. WOODBURN AND HEALTH SERVICES COUNCIL

The names of the members of the nine Standing Advisory Committees whose duty it will be to advise Mr. Arthur Woodburn, Secretary of State for Scotland, and the Health Services Council on various aspects of the National Health Service are printed below. The Committees have been set up by Mr. Woodburn after consultation with the Council. They are the Medical, Dental, Nursing and Midwifery, and Pharmaceutical Advisory Committees and Advisory Committees on Hospital and Specialist Services, Local Authority Services, General Practitioner Services, Health Services in the Highlands and Islands, and Health Centres.

Each Committee consists partly of members of the Health Services Council appointed by the Council and partly of persons, whether members of the Health Services Council or not, appointed by the Secretary of State after consultation with various representative organizations.

The Committees will advise on the Health Service matters with which they are concerned, both as they think fit and also on any questions that may be referred to them by the Secretary of State. They will report direct to the Secretary of State, but are required to inform the Health Services Council, who may express their views on the matter under consideration.

Medical Advisory Committee

(a) *Members appointed by Secretary of State.*—Dr. D. P. Cuthbertson, director, Rowett Research Institute, Aberdeenshire; Professor T. J. Mackie, professor of bacteriology, Edinburgh.

(b) *Members appointed by Health Services Council.*—Professor Dugald Baird, regius professor of midwifery, Aberdeen; Dr. A. D. Briggs, medical superintendent, Stobhill General Hospital, Glasgow; Professor D. F. Cappell, professor of pathology, Glasgow; Dr. W. G. Clark, M.O.H., Edinburgh; Dr. Mary Esslemont, Aberdeen; Professor G. B. Fleming, formerly professor of medical paediatrics, Glasgow; Dr. G. Matthew Fyfe, M.O.H., Fife; Mr. J. M. Graham, consulting surgeon, Edinburgh Royal Infirmary; Professor Sir David Henderson, professor of psychiatry, Edinburgh; Dr. J. R. Langmuir, chairman, Glasgow Local Medical Committee; Professor J. R. Learmonth, regius professor of clinical surgery and professor of surgery, Edinburgh; Dr. G. MacFeat, Douglas, Lanarkshire, chairman, Scottish Committee of the B.M.A.; Dr. I. H. Maciver, Fort William, member of Northern Regional Hospital Board; Professor J. D. McNee, regius professor of practice of medicine, Glasgow; Dr. A. F. Wilkie Millar, member of Edinburgh Executive Council; Professor T. Ferguson Rodger, professor of psychiatry, Glasgow; Dr. W. D. D. Small, president, Royal College of Physicians, Edinburgh; Professor Sir Sydney Smith, professor of medicine and Dean of the Faculty of Medicine, Edinburgh.

Dental Advisory Committee

(a) *Members appointed by Secretary of State.*—Mr. J. Aitchison, director of studies and Dean of Glasgow Dental Hospital and School; Mr. Hugh Miller Biggs, Glasgow; Mr. J. Campbell, Glasgow; Dr. H. M. Crombie, Aberdeen, representing oral surgery in general hospitals; Mr. Adam Cubie, Glasgow, representing general consultants; Mr. J. Johnston Davidson, dentist, Dundee; Mr. A. P. Husband, Glasgow; Mr. W. Russell Logan, Edinburgh, representing orthodontia; Mr. A. Marshall, Paisley, representing school and other priority services.

(b) *Members appointed by Health Services Council.*—Dr. R. C. Scott Dow, dental practitioner, teacher at Edinburgh Dental Hospital and School and examiner in dental surgery for Royal College of Surgeons, Edinburgh; Mr. James F. Henderson, dental practitioner, Motherwell; Mr. Thomas Rankin, Hamilton, consulting dental specialist to plastic and jaw injury units at Bangour and Ballochmyle.

Nursing and Midwifery Advisory Committee

(a) *Members appointed by Secretary of State.*—Miss M. I. Adams, matron, City Hospital, Edinburgh; Miss P. Bennett,

county nursing superintendent and supervisor of midwives for Midlothian and Peebles; Mrs. K. G. Brown, 1, Albyn Place, Edinburgh; Dr. W. L. Burgess, M.O.H., Dundee; Mr. J. Butler, Lenzie, Glasgow, mental nurse; Miss M. M. Cardno, orthopaedic ward sister, Royal Infirmary, Aberdeen; Miss R. Clarkson, matron, Royal Hospital for Sick Children, Glasgow; Miss I. Dean, matron, Royal Northern Infirmary, Inverness; Miss I. Hamilton, superintendent, Queen's Institute of District Nursing, Scottish Branch; Dr. W. F. T. Haultain, deputy chairman, Central Midwives Board for Scotland; Miss M. C. N. Lamb, assistant secretary, Royal College of Nursing, Scottish Board; Miss A. C. Shirra, lady superintendent, Glasgow Royal Mental Hospital; Lady Thomson, wife of the Lord Justice Clerk.

(b) *Members appointed by Health Services Council.*—Miss J. P. Ferlie, matron, Simpson Memorial Maternity Pavilion, Edinburgh; Miss C. M. Keachie, secretary, Scottish Health Visitors' Association; Miss E. G. Manners, matron, Royal Infirmary, Glasgow.

Pharmaceutical Advisory Committee

(a) *Members appointed by Secretary of State.*—Mr. John Boyd, Edinburgh, manager of Boots Cash Chemists in Scotland; Mr. C. A. Buick, Port Glasgow; Mr. Colin Campbell, manager, Retail Drug Department, S.C.W.S., Ltd., Shieldhall, Glasgow; Mr. P. H. Cartwright, Galashiels; Mr. David Currie, pharmacist at Foresthall Institution, Glasgow, and chairman, Guild of Public Pharmacists; Mr. C. W. Macfarlane, Dundee; Dr. I. M. Macleod, Inverness, member of Drug Accounts Committee; Mr. J. H. Ramsay, Edinburgh; Mr. G. D. Stewart, representative for East of Scotland on the Association of Pharmaceutical Employees.

(b) *Members appointed by Health Services Council.*—Mr. C. G. Drummond, pharmacist, Edinburgh; Dr. D. McCall, Edinburgh, assistant resident secretary, Pharmaceutical Society in Scotland.

(There is one vacancy, the filling of which is under consideration.)

Advisory Committee on Hospital and Specialist Services

(a) *Members appointed by Secretary of State.*—Dr. R. Bailey, Gogarburn Institute, Edinburgh; Mr. J. Brownlee, lay superintendent, Dumfries and Galloway Royal Infirmary; Mr. James McKelvie, member of South-Eastern Regional Hospital Board; Mr. J. MacKenzie, Craig Dunain Hospital, Inverness; Miss Eleanor Stewart, director, Glasgow Maternity and Samaritan Hospitals; Mr. Russell Paton, Edinburgh.

(b) *Members appointed by Health Services Council.*—Professor Dugald Baird; Dr. A. D. Briggs; Professor D. F. Cappell; Dr. R. C. Scott Dow; Lieutenant-Colonel J. C. Dundas, chairman, British Hospitals Association (Scottish Branch); Dr. Mary Esslemont, Aberdeen; Mr. W. F. Ferguson, secretary and treasurer, Edinburgh Royal Infirmary; Professor G. B. Fleming; Mr. J. M. Graham; Professor Sir David Henderson; Professor J. R. Learmonth; Sir H. Broun Lindsay, convener, East Lothian County Council, and chairman of County Councils Association; Dr. D. McCall; Dr. G. MacFeat; Professor J. D. McNee; Miss E. G. Manners; Professor T. Ferguson Rodger; Dr. W. D. D. Small; Professor Sir Sydney Smith; Captain Joseph Steel, director, Crichton Royal Institution, Dumfries; Captain J. P. Younger, director, Stirling Royal Infirmary.

Advisory Committee on Local Authority Services

(a) *Members appointed by Secretary of State.*—Dr. May Baird, chairman of North-Eastern Regional Hospital Board; Dr. J. Dunlop, formerly assistant M.O.H., Glasgow; Mr. J. Graham, convener, West Lothian County Council; Dr. Kate Harrower, Glasgow; Mr. R. P. Ligertwood, chairman, Public Health Committee, Aberdeen County; Provost Michael McGivern, convener, Public Health Committee, Coatbridge; Councillor William Reid, convener, Health Committee, Glasgow Corporation; Miss C. Sinclair, superintendent, Central Training Home, Edinburgh.

(b) *Members appointed by Health Services Council.*—Dr. W. G. Clark; Mr. Alexander Cunningham, member of

Stirling County Council; Miss J. P. Ferlie; Dr. G. Matthew Fyfe; Mr. James F. Henderson, dental practitioner, Motherwell; Miss C. Keachie; Sir H. Brown Lindsay; Mr. John Mann, convener, Lanark County Council; Mr. William O'Neill, member of Dundee Corporation; Professor T. Ferguson Rodger; Captain Joseph Steel; Provost James Young, Kirkcaldy.

Advisory Committee on General Practitioner Services

(a) *Members appointed by Secretary of State.*—Mr. G. G. C. Bain, chairman of Aberdeen City Executive Council; Councillor James Campbell, Edinburgh; Mr. M. B. Jackson, ophthalmic optician, Dunfermline; Mr. R. H. G. McGhee, Glasgow, member of Joint Ophthalmic Services Committee; Dr. E. Neil Reid, M.O.H., Stirling County; Professor W. J. B. Riddell, Glasgow.

(b) *Members appointed by Health Services Council.*—Mr. Alexander Cunningham; Dr. R. C. Scott Dow; Mr. C. G. Drummond; Dr. Mary Esslemont; Mr. James F. Henderson, dental practitioner, Motherwell; Dr. J. R. Langmuir; Dr. D. McCalt; Dr. G. MacFeat; Dr. I. H. Maciver; Dr. A. F. Wilkie Millar; Mr. William O'Neill; Mr. Thomas Rankin; Provost James Young, Kirkcaldy.

Advisory Committee on Health Services in the Highlands and Islands

(a) *Members appointed by Secretary of State.*—Dr. J. R. Anderson, Fortrose, Ross-shire; Mr. J. S. Banks, John o' Groats; Dr. W. N. Gray, Helmsdale, Sutherland; Mr. A. J. C. Hamilton, Inverness; Dr. J. L. Horne, M.O.H., Ross and Cromarty; Provost A. J. Mackenzie, Stornoway; Dr. A. J. Macleod, Lochmaddy, North Uist; Mr. Ian McClure, superintendent, Balfour Hospital, Kirkwall; Councillor Donald Macpherson, Inverness, chairman, Northern Regional Hospital Board; Provost Hugh Ross, Inverness.

(b) *Member appointed by Health Services Council.*—Dr. I. H. Maciver.

Advisory Committee on Health Centres

(a) *Members appointed by Secretary of State.*—Councillor W. P. Earsman, Edinburgh; Dr. D. Dale Logan, Newmains, Lanarkshire; Dr. John Winning, house surgeon and physician, Southern General Hospital, Glasgow.

(b) *Members appointed by Health Services Council.*—Dr. W. G. Clark; Mr. C. G. Drummond; Miss C. Keachie; Professor J. R. Learmonth; Mr. John Mann; Dr. A. F. Wilkie Millar; Mr. Thomas Rankin; Dr. W. D. D. Small; Professor Sir Sydney Smith.

Medical Ethics

Breaches of Confidence

Since the National Health Service started many doctors have been asked to give information about patients which, if disclosed, might amount to a breach of professional secrecy. It is an ethical tenet of the profession that medical men shall not voluntarily divulge to anyone, without the consent of the patient, information obtained in their professional relationship with their patients. Various certificates and forms of inquiry which pass through lay hands give ample opportunities for violation of this principle.

The Central Ethical Committee is anxious lest medical men, already deluged with a bewildering variety of official forms, lose sight of this principle and think that any form with an official appearance must be filled in. Any information which includes the identity of the patient should be given only with his consent. However, these ethical obligations are subject to the requirements of the law.

Scottish Headquarters

The telephone number of the Scottish Office of the B.M.A. has been changed to Edinburgh 33531, 33532, and 33533.

The Supplementary Estimates

SIR,—In the leading article on the Health Service entitled "Medical Economics" on Feb. 17, 1949, *The Times* stated that the Government had seriously underestimated the cost of the dental and ophthalmic services but that last July no one else had any better guess to offer. This statement is quite untrue, because any ophthalmic surgeon or optician could have told the Government that it was not possible to run a supplementary service on £2 million a year, and, more than that, many of us did tell the public.

I spoke at a meeting at Epsom on the Health Service in May, 1948, and my opponent was Mr. Somerville Hastings, M.P. I suggested to the audience that the Health Service would cost the taxpayer at least £250 million—a statement which Mr. Somerville Hastings contradicted, as he said the estimate was £150 million. I explained that I had given this higher figure because the Supplementary Ophthalmic Service at £2 million had been very seriously underestimated, and I gave as my reason the fact that in 1947 about 4,000,000 pairs of spectacles had been sold to the public, and it seemed unlikely that in 1948-9 fewer pairs would be supplied free. The average cost, with the examination fee and wholesale price of the spectacles, must work out at somewhere about £4 per pair. The rest was merely simple arithmetic for those *au fait* with the subject.

As many of us explained at the Representative Meeting, no single preparation had been made for the Health Service before it came in, and the resulting chaos is typical of all Socialist planning.—I am, etc.,

Camberley, Surrey,

LESLIE HARTLEY.

Representation of Tuberculosis Workers

SIR,—I have been instructed to reply to the letter from Drs. D. P. Sutherland and N. J. England (*Supplement*, Feb. 5, p. 63). Dr. Sutherland knows that the North-Western Tuberculosis Society has not been well supported in the past by the Liverpool Region, and therefore its officers are from Manchester and areas remote from here, who do not know our local problems. The representatives of the North-Western on the Joint Tuberculosis Council report to the Society, but the opinion of members is not sought before decisions are reached.

As the J.T.C. has asked to be represented on the Negotiating Committee, the other members of the committee will presume that this representative claims to speak for the doctors working in tuberculosis. When he is not representative of many of these workers, he has no right to make such a claim. The British Tuberculosis Association would have a better claim, but then again an inadequate one.

The J.T.C. has done good work in the past, but it is now trying to do work for which it is not suited, and if it is to do this new work it should be representative of regions and not of societies.—I am, etc.,

WILLIAM D. GRAY,
Hon. Sec., Liverpool Region
Tuberculosis Society.

Income of General Practitioners

SIR,—In your leading article of Nov. 13, 1948 (p. 864), you state that before the war the total professional incomes of general practitioners in England and Wales and Scotland added together amounted to rather more than £28 million, and that the total remuneration available now was approximately £45 million.

Dr. Charles Hill, in his letter to every member of the profession (*Supplement*, Oct. 23, 1948, p. 145), states as follows: "Before the war the total professional incomes of general practitioners in England, Wales, and Scotland added together amounted to rather more than £28 million. The total remuneration provided under the N.H.S. Acts for general practitioners is approximately £45 million."

You will doubtless appreciate that you have made two different statements, as Dr. Hill restricts the £45 million to the National Health Service alone, excluding any money earned in private practice. You cannot both be right. If Dr. Hill is not simply indulging in statistical fantasy then surely the medical men of this country should indeed be

affluent, and it is hard to understand all these distressed cries that are reaching your *Journal* at the present time. Many letters, indeed, suggest that the B.M.A. would have been well advised to concentrate upon finance rather than upon principles. Do you not now agree that if, having agreed and reaffirmed certain vital principles for the good of medicine, we had only had the stability and encouragement to stick to those principles the profession would not be in the deplorable position in which it finds itself to-day?—I am, etc.,

Bournemouth

E. DOUGLAS GRANGER.

* * The Secretary of the Association states: Professor Bradford Hill estimated the aggregate general-practitioner income before the war at rather more than £28 million. The sum now being distributed among general practitioners in the Service for the care of public patients is approximately £45 million. This sum is regarded as inadequate in total for the reasons set out in full in the Report of the General Medical Services Committee (*Supplement*, Feb. 19, pp. 83-5). If individual doctors are to be appropriately paid for their work there are needed first an adequate sum and secondly a fair distribution.

Salaries of Medical Research Workers

SIR,—We welcome the initiative shown by the Association of Scientific Workers in drawing up a memorandum on the salary of the research worker. We agree that the discrepancies between the rates of pay of research workers and clinical specialists is not only unjust to the former but also makes recruiting of research workers difficult. The threat of a drift of those already in research to more remunerative clinical appointments is real and must be avoided if we are to maintain and advance our international position in medicine. While we welcome the recommendation to increase the salaries of research workers, we disagree that research workers of any grade should have to accept a salary less than their colleagues in the clinical specialties, whether the difference is 10%, 20%, or any other figure. Such a proposal is tantamount to admitting that research is so much less important to society than clinical practice.

In the past, two main arguments have been used to limit the salaries of research workers. The first is that research is a vocation, and the second that research workers miss the "hurly-burly" of clinical work. In our opinion these arguments are illogical. If research workers were paid equally with other specialists there would be no economic limitation to the attraction of the best men into research. Furthermore, many research workers do not live in "ivory towers"; most of them have as active a life as clinicians, and many of them have a certain degree of clinical responsibility. We consider that some of the recommendations for the grading of workers in research may give rise to anomalies. We feel that nobody entering upon a research career should have to lose financially, and the salary of the research trainee should be adjusted to take this into account. On completion of a preliminary training period of twelve months or so he should be graded as a specialist registrar and be paid the corresponding salary. If the research worker is considered capable of continuing his work after a period of three to four years he should be accorded specialist status.

We should like to emphasize the necessity of according full specialist status to research workers at that stage in their career when, had they been engaged in purely clinical work, they would be regarded as specialist—i.e., about the age of 32, as mentioned in the Spens Report. We wish to avoid the anomaly of grossly underpaid research workers of considerable experience. The principle of equality of pay would allow easy transfer of a clinical specialist to full research work in his own specialty, and make use of the research capacity of a large number of clinical specialists.

The recommendation in the A.Sc.W. memorandum that administrative responsibility should be considered in the grading of those at present engaged in research is unwise and may encourage too close a parallel with the Civil Service system. The value of administrative ability is not denied, and where a research worker's duties involve additional administrative and organization work—e.g., director of department—he should receive additional remuneration. We agree with the memorandum in that non-medically qualified medical research workers should be paid on the same scale as the medically

qualified. We would welcome the opinions of other research workers on this issue.—We are, etc.,

BIRMINGHAM RESEARCH WORKERS.

* * The Council at its last meeting decided to set up a special committee to consider the best methods of securing the application of the recommendations of the Spens Committee to all full-time medically qualified salaried workers not remunerated through the National Health Service. Further details are given in the report of the proceedings of Council of Feb. 16.—Ed., B.M.J.

"Royal College of General Practitioners"

SIR,—For discussion and opinion a new Royal College to be called the Royal College of General Practitioners is suggested as an urgent need. Correspondence columns have for some time shown strong feeling that never have the interests of G.P.s been so mismanaged or neglected as in recent years. Influence, status, and material prosperity, it is complained, are waning. The advent of the new National Health Service has intensified this. Hundreds of doctors, allegedly, have been caused much financial and mental distress. For this the Ministry of Health has had chief blame.

Members of the B.M.A. and public, recent signs show, are gradually realizing the blame to be unjust. From evidence slowly emerging it would seem that few if any circumstances now causing hardship need have arisen had the facts (before July 5) been properly put for consideration or even, in some cases, revealed. In some instances terms offered by the Ministry but refused as unjust, are now realized as generous. A new approach to the Ministry, and from a new source, seems indicated. Where hardships are caused by unsound advice or poor judgment it scarcely seems sensible to ask the same advisers to get one out of these difficulties. Moreover, it seems a little hard on the advisers themselves.

For surgeons, physicians, and, more recently, gynaecologists Royal Colleges are considered necessary. Yet G.P.s are a far larger class. Their problems and difficulties, more varied and numerous, can often be estimated and remedied only by G.P.s. With the ever-increasing interests of physicians and surgeons, their two Colleges, it is now widely felt, have more than enough to do for their own. They can have but little time for and less knowledge of the needs of G.P.s.

The "Terms of Service" meeting at B.M.A. House (Jan. 27) was an interesting experience. It made one doubt, however, if we, the audience, or those on the platform had learnt much from recent events. More than ever did the need for the Royal College here advocated seem urgent. Unfortunately, written questions, the only ones permitted at the meeting, were too numerous for the subject of this letter, put down by me, to be reached. The G.P. is frequently referred to as the backbone and vitals of medicine. Here, by supporting the proposal of this letter, is opportunity to all ranks of the profession to give the lie to a sardonic rejoinder oft repeated that the G.P. is only so acclaimed where drudgery and ill-paid work are to be done.—I am, etc.,

London, W.2.

P. K. MURPHY.

Shortage of Hospital Beds

SIR,—In case some should take it seriously, may I answer Dr. A. Fry's criticism (*Supplement*, Feb. 12, p. 79) of hospitals in general? The unfortunate facts which he enumerates have, I believe, explanations other than those offered. Whereas he implies that medical attendances have not significantly increased among general practitioners, this is not so at many hospitals, where appointments in some special departments have doubled during the past six months.

The delay in the examination of the patient described, who was awaiting eye and E.N.T. appointments, might not be unconnected with the acknowledged heavy demand for free reading-glasses and hearing-aids.

I wonder whether the fracture quoted was due to a secondary hypernephroma? Surely pain can be relieved in a patient's own home?

The elderly man with pneumonia certainly required admission to hospital, but it must be remembered that the bed shortage which involved his refusal has often been increased by previous admissions of somewhat similar cases. I refer to those who become bedridden and who are blessed with relatives who

are unwilling to have them home again after their recovery from acute illness. Thus they remain in hospital and take a bed for perhaps a dozen or more acute cases per week, released by death. A healthier and happier health service will not be arrived at by describing hard-worked hospital staffs as cynical and without human feeling—I am etc
J N 10 F MEADE

SIR—I would be most grateful if you would kindly allow me a little space to support wholeheartedly Dr A Frew (*Supplement* Feb 12, p 79) when he complains bitterly of the shocking shortage of hospital beds and the difficulty of getting urgent cases into hospital. I can only say from my own recent experience that it is practically impossible to admit even the most urgent medical cases into hospital. When phoning the Emergency Bed Service—a splendid institution without blame—one usually gets the refreshing reply, "I am very sorry, Sir, but it will be almost impossible to get your patient into hospital to-day. I will try my best and phone the hospitals."

The other night I had to wait for more than two hours to get the reply from the EBS that nine hospitals in the London and Middlesex area were unable to admit a most urgent medical case of mine.

To ease this deplorable situation may I offer to the Minister of Health, free of charge, the suggestion to advise his nationalized hospitals to report every day, morning and evening, to the EBS the number of beds available (classified as surgical, medical, and children's beds). This would facilitate matters greatly and would enable the EBS, without losing most valuable time, to arrange the immediate admittance of the patient, avoiding countless inquiries about vacancies—I am etc,

London N 3

H SIMON

Reflections on N.H.S.

SIR—Dr R W Cockshut in his article "Reflections on N.H.S." (*Supplement* Jan 29, p 46) states that three years ago the BMA agreed to a comprehensive 100% service administered by the Ministry of Health. I would venture to suggest that this statement is not quite accurate. Representatives who were present at the May, 1945, SRM will remember that the meeting was only persuaded to accept a 100% service provided that ample safeguards are introduced to ensure that any member of the community, whatever his income, should be entitled to obtain his medical service in part or in whole privately as for example by grant in aid provisions. Is it now convenient to forget that proviso?

Are we to forget that, time and again, resolutions have been carried by the Representative Body with the object of preventing the penalization of the private patient and the doctor who wishes to treat him? Why does the Council now allow these resolutions to be forgotten? If it intended them to be put into effect, surely it would never have recommended the profession to enter the N.H.S. last July? All the BMA seems to care about now is the remuneration of doctors in the N.H.S. If it wishes to retain in its membership those of us who are opposed to a State monopoly of medicine it would do well to remember that some of us still believe in the principles for which our Australian colleagues are prepared to fight.

Some of us also remember that when the original questionnaire was distributed during the war we were never given the opportunity of saying if we wished to be paid on a 'fee-for-service' basis. Why? Perhaps our planners never really wished private practice to survive the onslaught of State medicine. I am, Sir, still a fighter, and wish our Australian friends good luck. May they stand firm!—I am, etc

Dorking Surrey

CYRIL E BEARE

Future Aims

SIR—As one of the present generation of medical students I was interested to read Dr John Frew's suggestions (*Supplement*, Jan 29, p 53) for our education in a new scale of values to teach us a new attitude to the National Health Service. One or two ideas particularly took my fancy—for instance that one of the ways of proving loyalty to the Service (so loudly protested by Dr Frew to be his aim) is to raise a new generation of "rebels" that will wreck the scheme "as it should be wrecked." Or again, that a good way to win back public support and

respect, and indeed our own self-respect, would be to use intensive propaganda in papers and periodicals and in flaring posters on hoardings and in every doctor's surgery to make the public despise (amongst a lot of other things that Dr Frew thinks despicable) the Service, however efficient we can make it.

I can see the public giving its support and respect to a body of responsible people behaving thus—on the one hand working and accepting payment under the Scheme because, according to Dr Frew's own confession, they were lured into it by monetary considerations, and on the other training their successors and inciting their patients by propaganda to wreck a nation-wide scheme enacted by Parliament.

But perhaps the most charming idea is that the B.M.A. should hire and pay generously poets, artists, philosophers, and [believe it or not] 'travellers and mountaineers to preach to our successors that there are nobler and greater values than the monetary ones for which we have sold our "freedom." Travellers and mountaineers paid generously to preach how little value money has—I think that the suggestion should be passed to the deans of all the medical schools, and questions on ethics (with particular reference to climbing in the Alps) should be included in the final MB papers.

But taking Dr Frew's last point seriously, may I suggest to him that people who form any opinions at all about "values" do not like being preached at, however eminent and well-qualified the preacher may be, preferring rather to decide for themselves what these values are, especially if the preachers, as would be the case were they chosen by Dr Frew, were selected not for their achievements but because their view of these highly debatable 'greater values' coincided with that of such unbending partisans as Dr Frew?—I am, etc,

London W 1

P MESTITT

Supplementary Ophthalmic Services

SIR—Mr S Black states in his letter to you (*Supplement* Feb 12, p 78) that 85% of all cases are seen by ophthalmic (sight testing) opticians. This seems to me an exaggerated claim put in for propaganda purposes and should be substantiated by some sort of proof. If his figure is even approximately correct it is another reason why it would be very foolish to attempt to lessen the cost of the Service by cutting down the fee payable to the ophthalmic medical practitioner, who must be getting an infinitesimal share of the total expenditure.

The whole point of my letter (*Supplement*, Jan 22, p 40) was to stress the need for more ophthalmic surgeons and to point out that lowering of fees would have a fatal effect on recruitment. We all want to see the permanent scheme established successfully as soon as possible, but this cannot be done with the numbers available at present. When the permanent scheme does come into force we will also need all the opticians that Mr Black and his organization can produce, and under skilled supervision they will be able to practise their art and do very well within its limitations.

As to Dr J H Austin (*Supplement*, Feb 12, p 78), I am not quite clear what his point of view is. I have had nearly thirty years' experience of out-patient hospital work and I am well aware of its limitations and frustrations. If one did personally do one's share of refractions at short periods one was backed by more or less competent assistant sight-testers who were nurses or other trained persons, and if the symptoms suggested a lack of muscle balance or the like it could be investigated under supervision, and the surgeon had the whole picture—mental, physical, and refractive—before him to enable him to prescribe glasses or otherwise. Does Dr Austin think this could be done equally well by an optician?

It has been pointed out to me that Mr Bevan has very little interest in the quality of his medical service, and is only interested in the quantity. This is where the medical profession must take its stand—and do so now—I am, etc,

Brixham Devon

CECIL B F TIVY

SIR—Mr S Black (*Supplement* Feb 12, p 78) makes great play in the Press of the need for a thorough examination taking half an hour in each case where a patient comes for refraction. His latest letter to your *Journal* stresses the need for full examination of the binocular apparatus, from which I would presume that he means examination on the synoptophore, Hess

chart, and binocular fields of vision, etc. Since he has at no time defined what he means by an adequate examination of the eye, I think it is essential that he should do so, so that we may know what he is talking about. Obviously a routine performance of a multitude of tests is of no value itself unless the examiner has some clinical acumen, and unnecessary testing merely confuses and alarms the patient.

The fact that 85% of the population is examined by opticians proves nothing in itself, but one might deduce from it that there is a great need for more ophthalmologists.—I am, etc.,

Farnborough, Hants.

P. L. ALLEN.

POINTS FROM LETTERS

Basic Salary

Dr. KENNETH MCFADYEAN (London, S.E.24) writes: According to the report of the Metropolitan Counties Branch in the *Supplement* of Feb. 5 (p. 55) Dr. Hill was asked, Why was a means test required in the allocation of basic salary? He is stated to have replied, "It was felt that a man who demanded this higher rate of remuneration from the local pool should prove justification." Apparently this answer was accepted without further discussion. It is amazing what one can get away with from a platform. The man, in demanding the basic salary, is only exercising his right on the basis of the contract under which he entered the Service. Dr. Hill's answer proves justification neither for the breach of contract nor for the introduction of a means test—i.e., reference to other sources of income, which have nothing to do with the man's professional earnings and less than nothing to do with the terms of the contract under which he joined the Service.

Certificates for Corsets

Dr. J. V. L. GRANT (Tamworth, Staffs) writes: The whole medical profession in general practice is irritated beyond endurance by the maddening demands of their women patients for certificates for corsets. This evening a woman of 76 of small physique came into my consulting-room and asked for a certificate to take to the woman agent of a corset firm, which I refused, explaining that she had no medical or surgical ailment. She was very annoyed and loudly informed all the people in my crowded waiting-room that I had actually refused her a certificate for corsets. Doubtless she will now take herself elsewhere. As each case honestly refused means five to ten minutes' exasperating argument and a dissatisfied patient, is it surprising that we perhaps prefer to certify the existence of an imaginary severe gastro- or visceroptosis? . . .

H.M. Forces Appointments

INDIAN MEDICAL SERVICE

Colonel J. Rodger, O.B.E., M.C., has retired.
Lieutenant-Colonel A. E. Kingston, O.B.E., has retired and has been granted the honorary rank of Colonel.

Lieutenant-Colonel G. R. M. Apsey and Major (War Substantive Lieutenant-Colonel) G. B. Jackson, C.B.E., have retired but continue to be borne on the Special List (ex-Indian Army) British Army while employed with the Pakistan Armed Forces.

Lieutenant-Colonels R. T. Hicks, O.B.E., H. H. Elliott, C.I.E., M.B.E., M.C., G. K. Graham, O.B.E., and G. P. F. Bower have retired.

Majors (War Substantive Lieutenant-Colonels) C. B. Jones, F. R. Cawthorn, O.B.E., and R. D. Scriven, M.C., have retired and have been granted the honorary rank of Colonel.

Majors M. C. L. Smith, V. D. Gordon, R. Y. Taylor, and J. Ford-Thomson have retired and have been granted the honorary rank of Lieutenant-Colonel.

Major M. L. A. Steele, M.B.E., has retired.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: D. M. N. Jones, M.B., D.P.H., Medical Officer, Uganda; A. J. Brown, M.R.C.S., Medical Officer (Out Islands), Bahamas; W. F. Cooper, M.B., D.P.H., Port Medical Officer, Aden; J. Kotowski, M.B., Medical Officer, Falkland Islands; E. Michalski, M.B., Medical Officer (District Services), Trinidad; J. M. Cruikshank, M.D., D.P.H., Director of Medical Services, Fiji, and Inspector-General of the South Pacific Health Service; J. H. Pottinger, M.B., D.T.M.&H., D.P.H., Assistant Director of Medical Services, Nigeria; L. P. Youngs, M.B., Senior Medical Officer, British Honduras; L. A. M. McShine, F.R.C.S., Medical Officer, Grade B, Trinidad; E. A. Renner, M.B., Assistant Director of Medical Services, Sierra Leone; W. D. Silvera, M.B., F.R.C.P., Senior Lecturer on Pathology, University College, Ibadan, Nigeria.

- 29 Tues. Special Representative Meeting, 10 a.m.
- 30 Wed. Special Representative Meeting, 10 a.m.

APRIL

- 4 Mon. Joint Committee of B.M.A. and National Veterinary Medical Association, 2 p.m.

Branch and Division Meetings to be Held

The following meetings have been arranged for consideration of (a) Report of Council on the Constitutional Position of the Association, and/or (b) Report of Council on Remuneration of General Practitioners in the National Health Service, and/or (c) Instruction of Representatives to Special Representative Meetings on March 29 and 30:

BARNSELY DIVISION.—At Queen's Hotel, Barnsley, Sunday, March 13, 3.30 p.m.

BRADFORD DIVISION.—At Royal Infirmary, Bradford, Wednesday, March 9, 8.15 p.m.

CAMBRIDGE AND HUNTINGDON DIVISION.—At Addenbrooke's Hospital, Cambridge, Saturday, March 12, 2.30 p.m. Annual general meeting.

CONSETT DIVISION.—At Commercial Hotel, Consett, Friday, March 11, 7.45 p.m.

GOOLE AND SELBY DIVISION.—At The Lodge, Snaith, Sunday, March 13, 3.30 p.m.

LEEDS DIVISION.—At Medical School, Leeds, Wednesday, March 9, 8.15 p.m.

SHEFFIELD DIVISION.—At Royal Victoria Hotel, Sheffield, Sunday, March 13, 7.30 p.m. All medical practitioners in the area of the Division are invited.

SUNDERLAND DIVISION.—At Royal Infirmary, Sunderland, Sunday, March 6, 3 p.m.

CHESTERFIELD DIVISION.—At Out-patient Department, Chesterfield Royal Hospital, Friday, March 11, 8.45 p.m. B.M.A. Lecture by Professor A. Haddow: "Biochemistry and the Control of Cancer."

DORSET DIVISION.—At the Old Shire Hall, Dorchester, Friday, March 11, 8.30 p.m. B.M.A. Lecture by Mr. Geoffrey Keynes: "The Thymus Gland and Myasthenia Gravis." The lecture will be illustrated with a coloured film.

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Tuesday, March 8, 8.30 p.m. Address by Mr. Anthony Green: "Radiotherapy" (with film).

LEWISHAM DIVISION.—At St. John's Hospital, Morden Hill, Lewisham, London, S.E., Monday, March 7, 8.30 p.m. Mr. John Howkins: Gynaecological and Obstetric Quiz.

NORTH BEDFORDSHIRE DIVISION.—At Bedford County Hospital, Friday, March 11, 8.30 p.m. Lantern lecture by Professor J. M. Smellie: "Infections in Infancy—Their Type, Incidence, Diagnosis, and Treatment."

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, March 10, 7.15 p.m. Clinical demonstration by Mr. C. Dudfield Rose: "On Ulcers." 8.45 p.m. Address by Mr. W. Lyle Stewart: "Medical and Veterinary Science—Some Dietetic and Infective Diseases of Common Interest."

PLYMOUTH DIVISION.—At South Devon and East Cornwall Hospital, Plymouth, Friday, March 11, 8.30 p.m. B.M.A. Lecture by Professor Lambert Rogers: "Sciatica."

ROCHESTER, CHATHAM AND GILLINGHAM DIVISION.—At St. Bartholomew's Hospital, Rochester, Thursday, March 10, 8.30 p.m. Clinical meeting. Lecture by Dr. Geoffrey Bourne: "The Diagnosis of Congenital Heart Disease."

SOUTH-WEST ESSEX DIVISION.—At Clinic Hall, Thorpe Coombe Maternity Hospital, Walthamstow, E., Wednesday, March 9, 8.30 p.m. Lecture by Mr. D. F. Ellison Nash: "Genito-urinary Disorders in Children."

TUNBRIDGE WELLS DIVISION.—At Kent and Sussex Hospital, Wednesday, March 9, 8.15 p.m. Dr. H. S. Banks: "Various Meningococcal Disease Syndromes."

WESTMINSTER AND HOLBORN DIVISION.—Joint meeting with Chelsea and Fulham and Kensington and Hammersmith Divisions at Postgraduate Medical School of the Royal Cancer Hospital, 24, Onslow Gardens, Fulham, S.W., Wednesday, March 9, 8.30 p.m. Mr. W. A. Mill: "Cancer of the Nose and Throat." Open to all medical practitioners in the area of the Divisions.

PARALYTIC POLIOMYELITIS

THE EARLY SYMPTOMS AND THE EFFECT OF PHYSICAL ACTIVITY
ON THE COURSE OF THE DISEASE

BY

W. RITCHIE RUSSELL, M.D., F.R.C.P., F.R.C.P.Ed.

Neurologist to the Radcliffe Infirmary, Oxford

Attempts to describe the early symptoms and signs of poliomyelitis present considerable difficulties, as the disease may show in many different ways. There are some excellent descriptions of the clinical features of the disease in the literature (e.g., Peabody, Draper, and Dochez, 1912), but recent epidemics have provided many more patients in the older age groups, and these can give a more detailed day-to-day account of their symptoms than has generally been available in the past. This paper is based on the careful questioning of 100 patients (59 males and 41 females) who were convalescent from poliomyelitis, and who were old enough to give a good account of their early symptoms. The number of pure bulbar cases is small, as these patients were often either unfit to be questioned or, having been discharged home after a short period of convalescence, no longer available. The method of recording the features of each case has been described (Russell, 1947), and specially prepared "Paramount" punch-cards were used for further analysis of the material.

The age groups were: under 11, 8 cases; 11-15, 21; 16-20, 17; 21-25, 20; over 25 years, 34.

The onset of the illness was in Great Britain in 85 cases, and in the remaining 15 in West Africa, the Middle East, or the Far East. Of the British cases 83 occurred during the 1947 epidemic, chiefly in the latter half of the outbreak.

Pattern of the Disease

In cases of paralytic poliomyelitis there may be three stages of the disease: the prodromal, the pre-paralytic, and the paralytic stages.

1. *The prodromal stage* is seen in less than half the cases, and precedes the pre-paralytic stage by several days. It consists of a brief and often slight illness lasting one or two days. Fever, sore throat, headache, or nasal catarrh are common symptoms. In most cases there is nothing specific about this stage of the disease, but in a few patients the symptoms of the prodromal stage resemble the spinal symptoms of the pre-paralytic stage.

2. *The pre-paralytic stage* is the acute and critical period of the disease. The virus is now multiplying in the central nervous system, and the battle to decide the fate of the spinal-cord cells is probably over before paralysis is detected. Spinal or meningeal symptoms develop and are often accompanied by fever, malaise, nausea, or vomiting. Pains in the spine, trunk, or limbs (spinal symptoms) are of special diagnostic value, while on examination the neck is stiff and the cerebrospinal fluid shows a marked increase of cells. Many examples of these symptoms are given below, but it must be emphasized that, though the appearance of spinal symptoms is very common, the severity of these symptoms is remarkably variable, and indeed the pains may be so slight that the robust patient considers them

to be negligible. The pre-paralytic stage usually begins abruptly, and in the 100 cases studied 89 had an abrupt onset. These can conveniently be referred to as "typical" cases. The cases described as "atypical" are those in which the onset was indefinite or in which prodromal symptoms appeared to merge into the pre-paralytic. In some cases the pre-paralytic stage appears in two phases with an interval of perhaps one or two days, during which time the patient feels he has recovered from the worst of the illness. In both these phases the spinal symptoms are often prominent.

3. *The Paralytic Stage.*—A remarkable feature of the paralytic stage is that the patient sometimes feels that he is better and that the illness is passing off, when paralysis appears. In other cases, however, severe limb pains, muscle spasm, and fever continue for many days.

Abortive cases are those in which no paralysis appears. There may merely be a short prodromal stage with perhaps sore throat and fever, or there may, on the other hand, be a pre-paralytic stage with spinal pains and characteristic changes in the cerebrospinal fluid. When there is only a prodromal stage the diagnosis of poliomyelitis virus infection can be little more than a guess, but when a typical pre-paralytic stage develops the diagnosis can often be made on clinical grounds with some confidence even though no paralysis occurs.

Prodromal Stage

As has been pointed out, the prodromal stage of the disease usually consists of a brief non-specific illness. In 34 of the 84 "typical" cases there were prodromal symptoms, usually lasting for one to three days and preceding the onset of spinal symptoms by an average of about five days. These symptoms often consist of a period of malaise with perhaps some fever, sore throat, headache, or cold in the head.

Short Prodromal Illness in a "Typical" Case

*Case 1 (2).** Schoolgirl aged 17. *Days 1 and 2.*—Sore throat with slight anorexia. Continued to attend school. *Days 3-7.*—Felt well; school as usual. *Day 8.*—Lumbar pain; continued school. *Day 9.*—Lumbar pain less severe in the forenoon. Ballet-dancing for 1½ hours. Lumbar pain worse in the evening, spreading to abdomen. *Day 10.*—Pains worse in back, trunk, neck, and head. Some nausea. Motored 140 miles and felt very ill. *Day 11.*—Pains less severe, but some pain in thighs; fever; restless and sleepless. Trunk muscles became paralysed, and there was weakness of the thighs and left arm.

Three months later there was severe paralysis of the abdominal and trunk muscles.

*The case notes are numbered seriatim and also according to the numbers in the records.

The occasional appearance of neurological symptoms in the prodromal stage is of special interest, as they suggest some invasion of the central nervous system by the virus even at this early stage.

Case with Neurological Symptoms in the Prodromal Stage

Case 2 (64). Female aged 38. Days 1-3:—Hyperaesthesia of skin of the abdomen. Day 4:—Hyperaesthesia continued; she felt well, and did an exceptionally heavy day's work in the house. Day 5:—Acute onset of pain in head and back, fever ($102^{\circ}\text{F.} = 38.9^{\circ}\text{C.}$) and irritability; continued housework all day. Day 6:—Symptoms continued. Stayed in bed for half the day. Day 7:—Left leg became paralysed.

A month later there was still severe paralysis of the left thigh and trunk muscles. (See also Case 16.)

Pre-paralytic Stage

In considering the symptoms of the pre-paralytic stage of the disease it must first be emphasized that neither the severity of symptoms during the pre-paralytic stage nor the degree of change in the cerebrospinal fluid gives any indication of the severity of ensuing paralysis.

Severe Pre-paralytic Symptoms but no Paralysis

Case 3 (28).—Schoolboy aged 12. No prodromal symptoms. Day 1:—Slight headache on waking, but he went to school and played football. That evening he developed severe headache and spinal pains in the dorsal and cervical regions. He vomited and was restless and sleepless that night. Day 2:—The symptoms continued. His neck was stiff and his temperature 100°F. (37.8°C.). His body and all his limbs were painful. He was admitted to hospital. Day 3:—The cerebrospinal fluid contained 73 cells per c.mm. and 45 mg. of protein per 100 ml.

Complete recovery ensued without paralysis.

As has been pointed out, the pre-paralytic stage is the most critical period of the illness, and it is only in this stage that any serious attempt can be made to recognize the disease before the onset of paralysis. Spinal or meningeal pains are especially important in diagnosis: they were reported in 95 of the 100 cases, and are analysed in Table I. This table shows that though several spinal

TABLE I.—Analysis of the Spinal or Meningeal Pains as they Appeared in the 95 Cases which Reported these Pains during the Pre-paralytic Stage

Pains in	Head	Neck	Back (Lumbar or Dorsal)	Back (Sacral)	Shoulders or Scapular Region	Chest or Abdomen	Thighs or Legs
Head	64	40	32	8	11	15	15
Neck		57	27	10	9	12	15
Back (lumbar or dorsal)			52	11	7	12	18
Back (sacral)				23	4	9	11
Shoulders or scapular region					13	4	4
Chest or abdomen						24	15
Thighs or legs							31

symptoms are common no one of them appears in more than two-thirds of the cases.

Pains in the Head

There is nothing specific about the headache when it occurs except that it is rarely intolerable, as it may be, for example, in meningitis: it may consist more of a soreness at the back of the head which is part of a spinal neck pain. Pain in the head appeared on the first day of the pre-paralytic stage in 45 of the 100 cases. In a few instances severe throbbing frontal pain was reported, but generally the headache was relatively insignificant. Study of the head pains may be of value in differential diagnosis, in that a patient who has spinal rigidity without severe headache is unlikely to be suffering from meningitis. Occa-

sionally pain in the head may appear without any of the more common spinal pains, as in the following case. This record also provides an example in which the onset of the pre-paralytic stage was vague and indefinite.

Indefinite Onset of Pre-paralytic Phase with Fever and Headache but No Spinal Pains

Case 4 (39). Male student aged 19. Days 1-3:—General malaise; felt progressively more "fed-up." Day 4:—Went for a cross-country run (four miles) to try to "work off" his malaise. He did not run easily, getting home with a struggle. Day 5:—Attended lectures; no marked symptoms. Day 6:—Fever and headache. Walked with difficulty 200 yds. to tell a relative he was ill; returned to bed. Day 7:—During the night he felt ill and weak when he got up for a drink. In the morning he was helped to the lavatory, but collapsed on the floor. This was the last time he walked.

Paralysis was almost complete and permanent in both lower limbs and lower trunk.

Spinal Pains

The spinal pains and paraesthesiae provide by far the most characteristic clinical features of the pre-paralytic stage. They were reported in 95 of the 100 cases. They often present features which are highly specific and of considerable interest. The severity of these pains varies greatly, as the following examples show. They are often localized, and may have a segmental distribution. The severity of the pain bears no relation to the severity of ultimate paralysis, but the site of pain at the onset of the pre-paralytic stage often corresponds to the site of maximum paralysis. For example, in the present series there were 15 cases of paralytic poliomyelitis in which pains in the thighs occurred on the first day of the pre-paralytic stage. In all but one of these, a bulbar case, the paralysis was maximum in, or more often confined to, the lower limbs

Severe Spinal Pain Preceding Severe Paralysis

Case 5 (50). Lieutenant in the R.N.V.R. aged 23. Day 1:—After normal duties as a barrack guard officer and a little cricket practice he developed pain in the neck at about 6 p.m. He slept badly that night. Day 2:—The pain in the neck became more severe, and in addition he developed severe sacral pain. This latter symptom made it impossible for him to rest in comfort. The buttocks were hyperaesthetic, so that he could not bear to sit or lie on his back. He went by car to report sick, but his back was so stiff that he had difficulty in getting into the car. He returned to his billet and went to bed, but could not rest; he got out of bed every hour or so to walk about for ten minutes in an unsuccessful attempt to obtain relief. He was sleepless and restless all night, moving continually while in bed in an attempt to get ease. Day 3:—Restlessness continued, and he felt very ill. He was removed to hospital in the evening, by which time his legs were rapidly becoming paralysed. There was almost complete and permanent paralysis of all muscles of the lower limbs and severe weakness of abdominal and lower spinal muscles. The upper limb were very slightly affected.

Severe Spinal Pain Preceding Slight Paralysis

Case 6 (25).—Housewife aged 30. Day 1:—Usual household duties. She felt very tired after a half-hour walk in the afternoon. In the evening she developed sacral pain and also pain in the right lower abdomen when walking. Day 2:—She stayed in bed. The sacral pain became severe and caused great restlessness. Pain in the neck developed. Day 3:—After a sleepless night the sacral and cervical pains were severe. She vomited frequently in the evening, which necessitated her getting out of bed every half-hour or so. The restlessness also made her feel she would like to get up and move about. Day 4:—No change. Day 5:—Pains less severe, but there developed paresis of the trunk, left thigh, and left leg muscles. Satisfactory recovery occurred during convalescence in all the affected muscles.

A history of pain in the neck is difficult to distinguish from stiffness, and the symptom is often more accurately described as a painful stiffness.

Neck Pain in the Pre-paralytic Stage Causing Difficulty with Diagnosis

Case 7 (35)—Male cinema operator aged 16. **Day 1**—Slight headache in the morning. Work as usual. About 8 p.m. there developed aching pain in the neck which made him disinclined to move his head. **Day 2**—After sleeping badly the pain in the neck continued; headache returned with some pain in the scapular region. Some vomiting and anorexia also occurred. He rested at home and went to a hospital out-patient department at 6 p.m. Here his neck and spine were examined at length, and he was told to return next day for x-ray examination. **Day 3**—He visited hospital, where he was again examined at length, and finally the x-ray examination was cancelled, and a lumbar puncture established the diagnosis. He had now developed such sacral pains that he was unable to lie on his back. He was admitted to hospital that evening, and by then there was paresis of the trunk and left thigh.

Six weeks later there was still paralysis of the muscles supplied by the upper dorsal cord, especially the intercostals. The limbs were not affected.

Neck Pain and Stiffness in Pre-paralytic Phase Followed by Paralysis of Neck Muscles

Case 8 (7)—Schoolgirl aged 11. **Day 1**—Developed pain and stiffness in neck, but felt quite well. **Days 2 and 3**—Pain gradually became worse. She continued to attend school, but got into trouble for not working well. She was obliged to hold her neck stiffly. Her father rubbed her neck and wrapped it up with a scarf. **Day 4**—Neck pain continued, also some fever, and she felt miserable. Attended school as usual. **Day 5**—Stayed in bed, and this relieved the neck pain. **Day 6**—Paralysis of neck muscles.

A month later there was almost complete paralysis of neck muscles; no weakness elsewhere.

Pains in Chest, Abdomen, or Thighs

Pains in the chest and abdomen may cause considerable diagnostic difficulty. Some characteristics which these pains may exhibit are apparent in the following records:

Pain in Chest as the Principal Early Pre-paralytic Symptom

Case 9 (10)—Male surveyor aged 43. **Day 1**—Having suffered from a sore throat for the previous eight days, he now developed a girdle sensation around his chest, which became tender to touch. **Day 2**—Chest pain continued, with fever, restlessness, and sleeplessness. **Day 3**—Vomiting and anorexia also experienced. **Day 4**—Pain in back and legs added to symptoms. Developed weakness of the right arm, trunk muscles, and right thigh.

Ten days later the muscular weakness was slight and recovering rapidly.

Pain in Chest as an Early Pre-paralytic Symptom

Case 10 (34)—A nurse, aged 21, who had been nursing cases of poliomyelitis (night duty) for a month. **Day 1**—About mid-day she developed bilateral chest pain, which was aggravated by a deep breath and was associated with hyperaesthesia: she could not bear the touch of bedclothes on her chest. She went on duty in the evening, but was sent to bed about 10 p.m. **Day 2**—Chest pain ceased and was replaced by severe frontal aching pain in the head and later by severe sacral pain, both of which continued for three weeks after paresis developed. **Day 3**—Pain in the front of thighs on moving. **Day 4**—Neck stiff. Weakness developed in left arm, trunk, left thigh, and left leg.

All the affected muscles recovered well within two months.

Severe Abdominal Pain as a Pre-paralytic Symptom

Case 11 (15)—Schoolgirl aged 10. **Day 1**—Sent home from school with sore throat, fever, and headache. Went to bed. **Day 3**—Felt well. **Day 4**—Got up, but was put to bed again

on Day 5 as she looked tired. **Day 6**—Pains in thighs and back. **Day 8**—Developed unbearable pain in lower abdomen, back, and thighs. Rolling about in agony. Severe vomiting. **Day 9**—Pains abated. Weakness of thighs and legs appeared, but this was not severe, and had largely recovered within three weeks.

Pain in Trunk on Movement as a Pre-paralytic Symptom

Case 12 (3)—Male machinist aged 25. **Day 1**—Slight stiffness in back and pain in the head. Did a heavy day's work. **Day 2**—Ditto. **Day 3**—Headache worse, and severe pain developed in thighs and a sharp pain in the left side of the chest each time he stepped forward with the left leg. Left leg also ached. **Day 4**—Vomiting added to the above symptoms. Weakness of abdominal muscles developed. **Day 5**—Pains ceased, but weakness spread to the thighs and legs.

A month later the left quadriceps was completely paralysed; all the other muscles affected were improving.

Discomfort in Chest and Abdominal Pain as Pre-paralytic Symptoms

Case 13 (44)—Schoolboy aged 16. **Day 1**—Feeling of constriction in the chest on taking a deep breath. Ran 100 yds race. **Day 2**—Pain in right iliac region on bending while playing a rackets match. **Day 3**—Above symptoms continued. Some malaise. Ran a half-mile race not so well as he expected. **Day 4**—Severe headache and pain in neck developed; fever, restlessness, and sleeplessness. School in morning. Tennis for half an hour; then reported sick for the first time and was sent to bed. That night he developed rapidly spreading severe paralysis, especially of lower limbs and trunk. A respirator was required for two weeks.

The permanent disability in this case was severe.

Pain in Thighs as a Pre-paralytic Symptom

Case 14 (48)—Accountant aged 27. **Days 1-4**—Malaise and slight fever. **Day 5**—Office work as usual. Slight sore throat; temperature normal. At night developed severe pains in both thighs. Walked about for some hours at night to get relief. **Day 6**—Thigh pains ceased. Temperature 102° F. (38.9° C.). Visited a friend and had difficulty in climbing stairs. Cycled one mile. Sat in a chair for some hours talking to a friend while his legs were gradually becoming paralysed. **Day 7**—Stayed in bed. By the evening he was completely paralysed from the chest downwards, and this complete paralysis of the lower limbs was permanent.

Spinal Paraesthesia as an Early Symptom

Case 15 (45)—Female clerk aged 29. **Day 1**—Nasal catarrh for past six days. Now developed pain in the back of the neck and a sensation like "cold water running down the spine." Work in office as usual. **Day 2**—Same symptoms, with vomiting and fever in addition. Rest at home, but she went out to visit doctor. **Day 3**—Symptoms less severe, resting at home. **Day 4**—Felt well; no pain now, but weakness of left arm developed.

A month later the left deltoid was still completely paralysed, but other affected muscles were recovering slowly.

Other Pre-paralytic Symptoms

Vertigo and a visual abnormality due to jerky movements of the eyes may appear early in the pre-paralytic phase when, as Bodian (1948) has shown, the virus is already in the brain-stem. Vomiting is common but seldom severe. It was reported in 29 of the 100 cases.

Nasal discharge, sore throat, diarrhoea, or constipation may occur in the pre-paralytic phase, but, being non-specific, these symptoms are usually of little value in early diagnosis.

Phases in the Pre-paralytic Stage

Several variations in the course of the disease occur which are most easily described by brief case reports. In some

instances it is difficult to ascertain whether or not the prodromal stage is merging with the pre-paralytic stage.

In the pre-paralytic stage of "typical" cases spinal symptoms usually become increasingly severe for two or three days, after which time paralysis appears and the spinal symptoms often subside quickly. In some cases, however, the course of the pre-paralytic stage is erratic and may consist of two or more phases, as in the following examples.

Case 16 (68).—Schoolboy, aged 12, attending a scout camp. *Day 1:*—Frontal headache and a pain over the anterior aspects of both thighs—"like a wire brush being pressed into the flesh." Tired and sleepy. *Days 2 and 3:*—Felt well, but noticed that running about brought back the pain in his head and thighs. Took part in all camp activities. *Day 4:*—Returned home, but still felt unusually tired. Average physical activity. *Day 7:*—Severe pains developed in head, thighs, and knees. He went to bed early, but was awakened at 9 p.m. by a nightmare to find the pains were worse than ever, and there was also abdominal pain. *Day 8:*—Pains continued. Vomiting, retention of urine, and fever—101.4° F. (38.55° C.). Severe paralysis of the left leg and thigh developed.

Case 17 (6).—Schoolboy aged 12. *Day 1:*—Pain in back of neck and back of knees; malaise and shivery feeling. Fever about 101° F. (38.3° C.). In bed for two days. *Day 3:*—Got up, but pyrexia returned. Returned to bed, where he remained for four days. *Days 10-14:*—Living very quietly at home. *Day 16:*—Resumed school. *Day 18:*—Played rugby football match. *Day 19 (evening):*—Headache and slight vomiting. Temperature 100° F. (37.8° C.). Went to bed. *Day 20:*—Developed pain in back of neck. *Day 21:*—Pains worse; also pain in dorsal spine. Girdle hyperalgesia and retention of urine. The cerebrospinal fluid contained 502 polymorphs, 280 lymphocytes, and 14 endothelial cells per c.mm., and there was 80 mg. of protein per 100 ml. *Day 22:*—Symptoms subsided. Temperature became normal, and no paralysis developed.

Case 18 (79).—Housewife, aged 30, two months pregnant. *Day 1:*—Mild neck stiffness. *Days 2-4:*—Felt well; usual housework. *Day 5:*—Lumbo-sacral pain and worsening of vomiting of pregnancy. *Days 6 and 7:*—Felt better, though vomiting continued. *Day 8:*—Lumbo-sacral pain recurred with greater severity, and there was also pain and stiffness of the neck and pains in both lower limbs. Temperature about 100.4° F. (38° C.). *Day 9:*—Symptoms continued. *Day 10:*—Cerebrospinal fluid contained 124 polymorphs and 117 lymphocytes per c.mm. and 75 mg. of protein per 100 ml. *Day 11:*—Paralysis of lower limbs trunk, and diaphragm. Respirator required.

This patient died later of pulmonary collapse.

Spread of Paralysis in Two Phases

Case 19 (1).—Housewife aged 33. *Day 1:*—Developed neck pain in the evening. *Day 2:*—Pains also in both shoulders. Some housework. *Day 3:*—Pains worse. Severe headache, restlessness, sleeplessness, and fever. Got up and went to see doctor. *Days 4 and 5:*—Symptoms continued. *Day 6:*—Paralysis of right shoulder and arm. Symptoms subsided. *Days 7 and 8:*—Felt well, but was restless. *Day 9:*—Improvement continued. Got up to have bed made; malaise and vomiting that evening. *Day 10:*—Paralysis spread to involve right thigh, right leg, and right intercostal muscles.

Another remarkable feature of the pre-paralytic stage occasionally observed is that the patient's symptoms may appear to be abating at the time the paralysis develops.

Abrupt Onset of Pre-paralytic Phase, Symptoms Subjectively Subsiding when Paralysis of Nearly all Muscles Developed

Case 20 (29).—Female factory-worker aged 21. *Day 1:*—Wakened with pain in the neck, back, and head. Worked all day in the factory; the journey to work involved travelling for an hour each way. She vomited and noticed something peculiar about her eyes; she thought she might be getting infantile paralysis. *Day 2:*—Slept well but still had pain in the neck, back, and head. She got up and walked (15 minutes) to see her doctor, who told her she had a chill, so she returned

home, went to bed, and took castor oil. *Day 3:*—Pains less severe. She remained in bed, and felt rather better. In the evening some friends called, and she sat up in bed talking to them for four hours (6 to 10 p.m.). Within an hour of her friends' leaving she noticed weakness of her limbs. *Day 4:*—By early morning she was totally paralysed and her respirations were failing; when she reached hospital she was severely cyanosed and was at once placed in a respirator. Ten weeks later there was very little recovery, and she was still unable to breathe without the respirator.

Thieffry (1947) has also drawn attention recently to paralysis occurring in some cases after the fever of the pre-paralytic stage has returned to normal.

Atypical Cases

The cases which show no definite onset of the spinal or meningeal symptoms may be conveniently termed "atypical" cases. There were 11 of this type among the 100 cases studied here. The onset of the pre-paralytic phase may appear indefinite when prodromal catarrhal symptoms merge into the spinal symptoms without the usual interval—see Case 9. The day of onset is also uncertain when the spinal symptoms are at first vague (see Cases 4 and 13), or they may continue for so many days before paralysis develops that the pattern of the disease is altered.

Prolonged Pre-paralytic Stage with Indefinite Onset

Case 21 (41).—Housewife aged 28. *Days 1 and 2:*—Tenderness of lower ribs for two days; no pain. *Days 3 and 4:*—Tenderness of upper abdomen for two days; no pain. *Days 5-7:*—Tenderness of lumbar spine for three days. Very light work. *Day 8:*—Tender on the anterior aspect of the right leg for two days. Very light work. *Day 9:*—In the morning sacral pain and stiffness developed. In the evening slight jerks of the right leg occurred with some pain in the leg. *Days 10 and 11:*—Sacral pain continued and slight fever developed.

The sacral pain continued until *Day 17*. The neck was stiff on admission to hospital on *Day 13*. On *Day 15* the cerebrospinal fluid contained 115 cells per c.mm. (10% polymorphs) and 70 mg. of protein per 100 ml. No paralysis developed except perhaps a transient slight paresis of the right leg.

Case 22 (77).—General practitioner aged 38. *Day 1:*—Malaise and headache in the evening. *Day 2:*—Rested at home. *Day 3:*—Listless and shivery; resumed practice. *Day 4:*—No change. *Day 5:*—Strenuous walk over the hills to "shake off" his malaise. *Days 6 and 7:*—Continued his practice, though symptoms persisted. *Day 8:*—Forced to go to bed with fever, severe frontal headache, and pain and stiffness of the neck. *Day 9:*—Excruciating sacral pain added to symptoms. *Day 10:*—Weakness of right arm and leg and, later, respiration. *Day 11:*—Respirator required; nearly all muscles paralysed. *Day 12:*—Died.

Discussion of Stages and Phases

Examination of these widely varying case records leads to certain conclusions. (1) Prodromal symptoms are usually non-specific, but sometimes they include spinal symptoms of a type suggesting that the virus is already in the spinal cord. (2) The symptoms of the pre-paralytic stage usually begin abruptly, get worse for 2, 3, or more days, and culminate in paralysis. Subjectively the patient may feel better when paralysis develops. (3) During the pre-paralytic stage the symptoms may abate and the patient feel that he has recovered from the illness, though the symptoms recur more violently and lead to paralysis. (4) Occasionally the paralysis may appear in two distinct phases, with an interval of several days between the first and second. (5) When there are two or more phases to the pre-paralytic stage each phase usually has spinal symptoms of the same type as occur in cases with only one pre-paralytic phase.

The pre-paralytic stage of poliomyelitis is therefore a highly critical time for the patient. Here the battle with

the invading virus reaches its climax. The amount of spinal cord damage must to a large extent be determined at this stage before paralysis actually supervenes. There is clinical evidence from the occurrence of spinal symptoms that in some cases this struggle is already being fought within the central nervous system during the prodromal stage. Experimental studies support this possibility, as Horstmann (1948) has pointed out.

The two or more phases which may occur in the pre-paralytic stage suggest that the body may appear to conquer its foe, but after apparent victory something "goes wrong"; the virus triumphs at the second assault and paralysis results. The sudden triumph by the virus and its simultaneous appearance throughout nearly all parts of the spinal cord and brain-stem is a puzzling feature of experimental poliomyelitis.

According to Bodian (1948) the virus reaches its maximum concentration in the spinal cord twenty-four hours before paralysis, and as the paralysis is advancing the concentration of the virus drops rapidly. Experimental infections do not, however, often run a biphasic course, and one can only speculate on the likely concentrations of virus in the spinal cord at the various stages of a human case with a biphasic pre-paralytic stage.

Effect of Physical Activity on Motor Neurone Vulnerability to the Virus

In the literature of poliomyelitis there are many reports regarding cases in which violent physical exertion appeared to precipitate a severe or fatal paralysis or in which the muscles specially exercised were those most paralysed. Reference to these cases is made by Levinson *et al.* (1945), who have also made observations on the effect of fatigue and cold in increasing the amount of paralysis in monkeys infected with the virus.

In a preliminary report on the present study (Russell, 1947) the effect of exercise upon the final paralysis was examined statistically, and it was shown that the continuance of even moderate physical activity in the pre-paralytic stage is dangerous. Hargreaves (1948) has to a large extent confirmed these observations.

If physical activity has this important influence on the course of the disease it might show its influence in one of three ways: (1) Physical activity might bring on the acute pre-paralytic phase in a patient who would otherwise have an abortive attack with no more than prodromal symptoms or perhaps no noticeable symptoms at all. (2) Physical activity after the onset of pre-paralytic symptoms might increase the risk or indeed determine the amount and site of paralysis. (3) Physical activity after the subsidence of a first phase of the pre-paralytic stage might lead to a recurrence of the meningeal symptoms and thus increase the danger of paralysis.

Excessive Physical Activity Preceding Pre-paralytic Stage

With regard to the first of these possibilities a study of the case records suggests that excessive physical activity may sometimes play a part in deciding the onset of the dangerous pre-paralytic stage. The evidence of this consists merely in a history of extra physical activity within twenty-four hours of the onset of the pre-paralytic stage in 17 of the 100 cases.

The correlation of physical activity with this particular aspect of the disease is difficult to handle statistically, but the following cases certainly suggest that violent physical exertion may sometimes be a factor which determines that a prodromal illness or latent infection will not remain abortive but will develop the spinal symptoms of the pre-paralytic stage with the consequent danger of paralysis.

This possible effect of physical activity in precipitating the pre-paralytic stage of the disease must be clearly distinguished from the effect of physical activity during the pre-paralytic stage on the severity of paralysis. This latter aspect can be handled with confidence statistically, and will be referred to later.

Special Physical Activity in Prodromal Stage Followed Within 24 Hours by Acute Spinal Symptoms and Later by Paralysis

Case 23 (89).—Airman aged 33. Day 1.—Headache and sore throat; off duty for one day. Days 2–6.—Felt well. Day 7.—After usual work played rugby football. Day 8.—Severe pain in spine and chest with fever. Continued work. Day 9.—Severe paralysis of all muscles of the lower limbs and lower trunk.

Case 24 (91).—Airman aged 22. Days 1 and 2.—Sore throat and headache. Quiet days on board ship. Day 3.—Ashore walking round all day. In evening developed sacral pain. Day 7.—Paralysis of abdominal muscles and thighs.

Case 25 (84).—Airman aged 23. Day 1.—Cold in head and sore throat for two days. Days 3–9.—Tired, but weather very hot. Day 10.—Very hard badminton match. In evening developed fever and pain in head and neck. Day 13.—Severe paralysis of both upper limbs.

Case 26 (71).—Schoolboy aged 14. Had cold for three or four days. A week later he played rugby football, and on the night following developed pain in the back and a few days later slight abdominal paralysis.

There are four further examples of this type among the group of "typical" cases with prodromal symptoms.

There are also nine among the "typical" cases without prodromal symptoms in which the pre-paralytic stage with spinal symptoms was immediately (within two to twenty-four hours) preceded by some special physical activity as in the following examples.

Special Physical Activity Immediately Preceding Spinal Symptoms in "Typical" Cases with No Reported Prodromal Symptoms

Case 3 (28).—Male aged 12. Football six hours before onset.

Case 19 (1).—Female aged 33. Six hours spent washing for a school, extra to usual work, eight hours before onset.

Case 27 (4).—Male aged 13. Long run (several miles) soon after beginning of school term, sixteen hours before onset.

Case 28 (86).—Male aged 22. Tennis tournament all day twenty-four hours before onset. Yachting six hours before onset.

Case 29 (94).—Male aged 21. Tennis tournament twenty-four hours before onset.

Case 30 (90).—Male aged 28. Playing squash-rackets three hours before onset.

Physical Activity During the Pre-paralytic Phase and its Influence on the Severity of Paralysis

In order to correlate the possible effect of physical activity during the pre-paralytic stage with the severity of paralysis a method of scoring has been used for both the amount of physical activity and the severity of paralysis (Russell, 1947).

In Table II the days of the disease are numbered backwards from the day paralysis appeared (P-1, P-2, P-3,

TABLE II.—Physical Activity on the Days Preceding Paralysis Compared in Cases Developing (1) Slight, (2) Moderate or Severe Paralysis

Severity of Paralysis	No. of Patients in Each Group who Undertook Moderate or Severe Physical Activity During Each of the Four Days Preceding Paralysis (P-1, P-2, P-3, P-4)			
	P-1	P-2	P-3	P-4
Slight (33 cases)	0	6 (18%)	11 (33%)	18 (54%)
Moderate or severe (59 cases)	14 (23%)	35 (59%)	51 (86%)	53 (90%)

and P-4). The cases are divided into two groups: (1) slight paralysis—good recovery expected; (2) moderate or severe paralysis—permanent disability expected. The proportion of cases in each group which continued physical activity during these four days is shown. It is obvious that non-paralytic cases cannot be included in this table.

Another method of investigating this matter is by numbering the days of the disease from the onset of the pre-paralytic stage; but this can only be done in the "typical" cases with an abrupt onset of spinal symptoms. In Table III

TABLE III.—Comparison, in "Typical" Cases Only, Between the Severity of Paralysis and the Amount of Physical Activity after the Onset of the Pre-paralytic Stage

Amount of Physical Activity After Onset of Pre-paralytic Stage	Permanent Paralysis		
	Slight or None	Moderate	Severe or Fatal
Nil or slight for less than 24 hours ..	30	6	2
Moderate or severe for less than 24 hours ..	6	9	7
Slight, moderate, or severe for more than 24 hours	2	12	15
Totals	38	27	24

the ultimate severity of paralysis in the typical cases is compared with the amount of exercise continued after the start of the pre-paralytic stage.

Both Tables I and II show a remarkable and highly significant increase of severe paralysis in association with a continuance of physical activity in the days preceding paralysis.

The question naturally arises why certain patients continue average or severe activities after the onset of symptoms. As has already been emphasized, these symptoms may be quite slight, but there is certainly no evidence to suggest that those patients destined for severe paralysis have less disturbing pre-paralytic symptoms than have the slight cases. The question cannot be answered with great confidence, but my impression is that often those who continue physical activity after the symptoms begin either are relatively insensitive to pain or have more than the average courage or incentive to continue work or play in spite of illness. There is certainly no doubt that many of those most severely crippled have a remarkable strength of character and great powers of endurance. It has been said that the disease picks out the best child of the family.

Many young children pay little attention to bodily pains, and this may explain an apparent absence of spinal pain in some infants developing poliomyelitis.

The Effect of Trauma

There are a few reported cases of poliomyelitis in which local trauma appeared to determine the site of maximum paralysis (see Levinson *et al.*, 1945). In such a case, for example, poliomyelitis occurring soon after an arm fracture would lead to paralysis affecting chiefly the fractured arm. This type of case, infrequent though it is, raises the possibility either that peripheral trauma provides the virus with easy access to the neurones or that it modifies the physiology of the spinal cord cells of the segments concerned in such a way as to make them more vulnerable to the virus.

Experimental studies on these lines provide much food for thought. Hurst (1930) found that injection of the virus into the sciatic nerve led to paralysis beginning in the same leg only if the nerve is deliberately injured by the injecting needle. In such an experiment the paralysis develops without the preceding fever noticed in other forms of experimental infection (e.g., intracerebral). Infection was prevented if the injected nerve was excised within twenty-

four hours of injection. Howe and Bodian (1942) found that section of nerve roots some days before infection protected the corresponding nerve cells from attack by the virus. German and Trask (1938) injected virus into denervated skin caused by section of anterior and posterior roots, denervation of a skin flap, or denervation of a whole lower limb from the mid-thigh level. They found that not only did the disease caused by injection into denervated skin develop with the normal pattern, but that the animals infected after these operations were more vulnerable and developed more severe paralysis than the controls. The limbs on the side of the operation were usually affected first. From these experiments it was clear that, though the virus did not have any nerves along which to travel, it reached the spinal cord just as quickly as in the controls, and apparently found that the previous operations had increased the vulnerability of the spinal cord cells in the appropriate segments.

These observations necessitate reconsideration of the theory that the virus travels principally via the neurones. This theory is based on a number of studies. Hurst's work on the sciatic nerve has just been referred to. In the tragic accidents with poliomyelitis "vaccine" reported by Leake (1935) the arm inoculated was always the first to be paralysed. After intracerebral inoculation of the virus paralysis appears first in the contralateral limbs (Jungeblut and Spring, 1930).

Though these observations are generally held to indicate neuronal transmission of the virus, it is also possible that this pattern of spread is due not to the trauma providing neuronal access but to the trauma modifying the physiology and increasing the vulnerability of the spinal cord cells with which the traumatized area is in anatomical neuronal connexion.

The following case records may be relevant to this problem.

T.A.B. Inoculation on Right Arm. Acute Illness 7 Days Later. Paralysis of Right Arm

Case 31 (12).—A newly conscripted soldier aged 18. Day 1:—A T.A.B. inoculation was given by subcutaneous injection on the outer side of the right upper arm. The arm was stiff for two days, but he did not feel well during the week following, so he rested most of the time. Day 7:—In the evening a painful stiffness of the neck and scapular region developed. There was also anorexia. Day 8:—Headache and fever (103° F.=39.4° C.) were added to symptoms. Day 9:—The cerebrospinal fluid contained 133 white cells per c.mm. and 75 mg. of protein per 100 ml. Day 10:—Paralysis of right deltoid, biceps, and triceps. No other muscles were affected.

Severe Paralysis of Lower Limbs and Trunk 10 Days After Several Intramuscular Injections in Buttocks

Case 32 (101).—Schoolgirl aged 10. Day 1:—Severe earache, for which she was given intramuscular injections of penicillin into the buttocks every four hours for three days. Day 8:—Felt tired and had a slight headache on waking. Though her temperature was normal at lunch-time it was raised a little by the evening. Slight activity during the forenoon; then went to bed. Day 9:—Slight sore throat added to symptoms. In bed all day. Day 10:—Felt quite well. In bed all day except that she got up to motor home—one hour's run. Day 11:—Developed moderately severe pains in both thighs. In bed all day. Day 12:—Severe paralysis of both lower limbs and lower trunk muscles. This was still very severe two months later.

(Her brother also had pains in the thighs at about the same time, but did not develop paralysis.)

If these two examples record anything more than a remarkable coincidence then they suggest that at a certain early stage of virus infection even the trauma of an

injection will increase the vulnerability of that part of the spinal cord which supplies the site of injection. The well-recognized effect of tonsillectomy on increasing the liability to bulbar palsy may act in the same way (Horstmann, 1948).

Type of Physical Activity Related to Site of Paralysis

There have been many reported instances of the paralysis of poliomyelitis being worse in those muscles which were most exercised at the onset of the illness. Table IV gives

TABLE IV—*Poliomyelitis. Comparison Between Type of Exercise and Permanent Paralysis*

Case No.	Day of Exercise in Relation to Day of Onset of Pre-paralytic Stage (D) and to Day of Paralysis (P)		Type of Exercise	Site and Severity of Paralysis (Slight —, Moderate ++, Severe ---)
	D	P		
13 (44)	3	-1	Half-mile race	Lower limbs ---
4 (35)	-1	-3	Four-mile race	Trunk + + Lower limbs ---
(52)	1	-1	Schoolboy playing organ for 1 hour R. leg: special strain	L. arm + + R. leg and thigh only + + +
70	1	-1	Throwing chain with R. arm (surveyor)	R. upper limb + + +
(51)	3	-1	Severe asthma	L. leg --- Abdomen --- Intercostals --- R. shoulder --- R. thigh --- R. arm and hand only + + +
183	1	-3	Playing piano for 1½ hours. R. hand: special strain in the piece played	Trunk and thighs + + + Less ---
17 (6)	1, 2, 3	-2, -1	Milkman—on feet all day	Both lower limbs + + + Universal severe paralysis; respirator: died 3 months later
(35)	1 to 7	-7 to -1	Heavy-truck driving	
(9)	1, 2	-1, -2	Heavy training, carrying machine-guns uphill 6 hours before paralysis	

Cases in which the muscles used most during the pre-paralytic stage were most severely paralysed.

several examples of this correlation between the type of physical activity and the site of maximum paralysis, and thus provides further evidence regarding the harmful effect of physical activity.

Conclusions

These observations help to consolidate views held by many experienced physicians: first, that the pre-paralytic stage of poliomyelitis, though variable, can often be recognized correctly; and, secondly, that physical activity at the onset of the disease is dangerous.

The tables which illustrate this paper indicate that *complete physical quiet from the onset of symptoms will seldom fail to prevent serious paralysis, while strenuous or even moderate physical activity at this stage is highly dangerous.* On theoretical grounds, therefore, it should be possible to prevent many of the grave cases which occur. For example, those who have the care of children, especially at holiday camps and schools, should learn of the ways in which the disease can present. Sports meetings and special athletic contests should, if possible, be held outside the season for poliomyelitis. During an epidemic physical activity should not be exhausting, and should be avoided entirely during minor illnesses. The dangerous idea that symptoms may be "worked off" by exercise should be countered emphatically.

During the acute stage of the disease perhaps the chief aim in treatment should be to maintain for the patient a state of mental and physical quiet. He should be surrounded by an atmosphere of calm and confident efficiency. Sedatives and analgesics are often essential, but little information is available on what are the best sedatives to use in this disease. Probably all sedatives are safe in moderate doses, but patients in the acute stage of the disease must,

especially if on sedative treatment, be watched carefully lest respiratory paralysis develop during sleep.

The not uncommon need to rest the muscles of respiration should be kept in mind. Slight respiratory weakness leads to alarm and sleeplessness. Weakness of coughing is an early sign. This can often be relieved by using the artificial respirator for a short time, but in mild cases a lung inflator is particularly valuable, and is less worrying to the patient. A lung inflator* can be used to give highly effective artificial respiration for a period of hours if necessary, and should be at hand in all cases of paralytic poliomyelitis during the acute stage of the disease. In respirator cases a lung inflator is especially valuable, as it enables artificial respiration to be fully maintained when the patient is removed from the respirator for nursing and other purposes.

Summary

In 100 cases of poliomyelitis the early symptoms have been studied in detail.

The prodromal stage, when present, consists usually of a brief non-specific illness, but neurological symptoms occasionally appear even at this early stage.

The pre-paralytic stage is the most critical period of the disease. Spinal symptoms in "typical" cases begin abruptly, and occurred in 95 of the 100 cases. They are of great value in diagnosis, but are very variable as regards both type and severity.

Two or more phases of the pre-paralytic stage may appear, and paralysis may spread in two or more stages. The spinal symptoms may subside before paralysis develops.

In "atypical" cases the onset of the pre-paralytic stage is vague, and the symptoms of a prodromal stage may appear to merge into the pre-paralytic stage.

An unusual amount of physical activity immediately preceded the pre-paralytic stage in 14 of the 100 cases.

Complete physical rest in bed from the onset of the pre-paralytic stage greatly reduces the danger of severe paralysis. Severe physical activity at this stage is almost suicidal, while the continuance of even average physical activity is dangerous.

The possible effect of trauma in localizing the disease is considered.

During an epidemic physical activity should be avoided entirely in minor illnesses. The highly dangerous belief that malaise and other vague symptoms should be "worked off" by exercise requires correction.

I am greatly indebted to Drs. R. J. Porter, George Smyth, and Elias-Jones, who between them contributed 34 carefully documented records towards this series of cases. Many have allowed me to study the cases under their care, and in this connexion I am especially grateful to Dr. W. H. Kelleher, Dr. A. Joe, and the Medical Officer of Health for Oxford. Dr. P. M. Daniel, Professor Ryle, and Dr. Allan McFarlane have each given me most valuable criticism of the manuscript. Dr. Weston Hurst has given me much helpful information.

THE MIND AND THE SKIN

BY

I. B. SNEDDON, M.B., M.R.C.P.

Physician to the Skin Department, United Sheffield Hospitals

In 1884 Jonathan Hutchinson started a series of lectures with the following sentences: "Our forefathers, who knew far less about the detail of pathology than we do, attached far more importance to such matters as temperament and diathesis. They were accustomed to prescribe for a man's temperament; we think only of his disease, and turn aside with weariness from classifications of diathesis in which the physicians of an older day delighted. Although to a large extent this change of sentiment has been the result of advance in knowledge, yet I think it might easily be shown that it has gone too far, and that we now neglect unwisely the study of those differences between man and man of which, for the most part, physiology takes no cognizance, but which may yet prove of much importance in modifying the processes of disease."

That extract is as true to-day as it was 65 years ago. That the skin can portray emotions and give a picture of man's temperament is often overlooked. Ingram in 1933 pointed out that permanent changes can occur in the skin as a result of emotional changes, but it is only recently that this has been generally accepted, and there still exists rock-like opposition in some quarters.

Few would deny that certain emotions are displayed for all to see in the changing responses of the skin. The blush of shame, the flush of anger, the pallor of fear, are commonplace examples of this phenomenon. It is impossible to practise dermatology without realizing that these dynamic changes may produce a permanent change in the skin. However, it is extremely difficult to prove this to the outside observer. Professor Witts (1948) said, "How easy it is to aver that mental ideas or states can be converted into physical disease processes as they can be converted into phobias or hysterical paralyses, but how difficult it is to prove it or to demonstrate the mechanism!"

It is becoming more and more apparent that the onset of any given disease is a result of the interplay of many factors; hereditary predisposition, allergy, bacterial infection, immunity, and mental conflicts all play a part. It is most important that skin disease should be classed as a derangement of the whole body, and not just as an inflamed patch of skin. The mind plays a large part in the production of some of the common skin diseases, but I do not want to give you the impression that I think that all skin disease is produced by derangement of the mind or that if an adequate organic cause can be found it should be neglected.

Here is a brief classification of the skin conditions in which the psychogenic factor plays some part in the causation:

Group 1.—Dermatoses Always Psychic in Origin.—(a) Delusion of parasitosis (acarophobia) and other obsessional states. (b) Dermatitis factitia. (c) Neurotic excoriations. (d) Trichotillomania.

Group 2.—Dermatoses with a Large Psychogenic Factor.—(a) Neurodermatitis. (b) Pruritus ani and vulvae. (c) Atopic eczema. (d) Nummular eczema. (e) Rosacea.

Group 3.—Dermatoses Sometimes Precipitated by Psychogenic Factors.—(a) Urticaria. (b) Hyperhidrosis. (c) Cheiropompholyx. (d) Seborrhoeic dermatitis. (e) Psoriasis. (f) Alopecia areata.

Group 1

The cases in this group are of interest in that their aetiology is accepted by most people without much argument.

On the whole they are rarities, and therefore I do not want to give much space to them. They include:

(a) *Delusion of Parasitosis, or Acarophobia.*—This usually occurs in an elderly person living alone who complains that he or she is infested with imaginary mites which run about his or her body. An old lady who came to me not long ago stated that she had three separate colonies, all different colours, living beneath her toe-nails, in her umbilicus, and in her hair. She produced a screw of paper in which were bits of dust, skin, scales, etc., which she stated were the mites. Her main reason for coming was that she thought people in church could see them and were talking about her. On examination her skin showed no abnormality, though in some cases excoriations are present, as there is often an associated senile pruritus. Her belief of infestation was a delusion, and this was part of an involutional melancholia. Other psychoses may give rise to these delusions, among them toxic states, schizophrenia, and arteriosclerotic paranoia. In this group psychiatric treatment is the only thing possible, and I believe my old lady was helped by electric convulsion therapy.

(b) *Dermatitis Factitia.*—These skin lesions are self-inflicted and can be diagnosed by the bizarre characters, which do not fit in with any common dermatosis. Occasionally the lesions are produced consciously for gain, as by the man who wishes to be invalided from the Services or who aggravates an industrial dermatitis to continue to draw compensation. Most commonly, however, the lesions occur in women with a hysterical personality who desire sympathy. Occasionally no apparent reasonable cause can be found, and then it seems to be a true psychosis. I remember very well

a woman who ulcerated one leg until it had to be removed; she then started on the other. Fig. 1 shows a typical factitious lesion in a girl of 16. No cause for her action was found by the psychiatrist.

FIG. 1.—Photograph of girl with dermatitis factitia.

Even when confronted with evidence that the lesion heals when covered by an occlusive dressing it is rare to get a confession, and I think psychiatrists agree that these cases are most difficult to cure.

(c) Closely allied to dermatitis factitia are those rare cases of neurotic excoriations that are usually a result of some trivial organic skin disease which is perpetuated in hysterical individuals by constant scratching.

(d) *Trichotillomania.*—The habit of pulling out hair is most commonly seen in children of nervous temperament and in mental defectives.

Group 2

In this group—comprising the dermatoses in which the psychogenic factors play a predominant part—are those patients who crowd the out-patient departments and surgeries. These cases occur in individuals who are born with a constitutional inadequacy of the nervous system. They belong to the same group as those seen in other departments of medicine, with nervous dyspepsia, effort syndromes, irritable colons, anxiety headaches, and the other innumerable psychosomatic syndromes. The fact that they develop a skin abnormality rather than one of the other manifestations seems in many cases to be a matter of chance or rather opportunism.

Neurodermatitis

If one takes the common itching syndrome neurodermatitis, there is often an organic precipitating cause, and then the irritable nervous make-up takes over and perpetuates the condition. A typical example follows.

Case 1.—A woman aged 50, obsessively house-proud and a chronic worrier, had brought up her only daughter to be a bit above the neighbours and was intensely proud of her. Some six months before she attended the out-patient department her

FIG. 2.—Case 1, showing band of neurodermatitis on the neck.

find herself scratching. She had always prided herself on her good skin and keeping clean, and the fact that she had this skin lesion, which other people could see, increased her anxiety, and she ceased to meet her friends, as she was ashamed. It was at this stage that she attended hospital. On examination the clinical lesion was a band of lichenified papules with an excoriated surface on the back of her neck (Fig. 2). The lichenification was evidence of long-continued rubbing, and the localized lesion with clear-cut edges was typical of probably the most common psychodermatosis—localized neurodermatitis. It was apparent that there must have been some psychogenic cause, and with only a little encouragement she gave us the whole story.

Here one can see the three main factors: (1) constitutional make-up, (2) acute emotional tension, and (3) an organic lesion—the boil; this led to the production of the lesion, the presence of which caused even more anxiety.

The great majority of these cases of dry localized neurodermatitis have some recent increase in nervous tension on the constitutional nervous state which Becker (1932) called "neuro-circulatory instability." Favourite sites for the lesions are the occiput and nape of the neck, behind the ears, the eyelids, the antecubital fossae, the backs of the arms, the inner side of the thigh, and the vulva and perianal regions.

On the whole the personality type which develops neurodermatitis is the hard-working, over-conscientious, meticulous, overclean, yet aggressive obsessional persons to whom life is a stern battle relieved by a few light touches and who bottle up their emotions.

Stokes (1940) has named this personality the "tension frame of mind," and I think it very apt. These people have an inborn feeling of inadequacy. Their lives are governed by the conflict of "I must" with "I can't" and "I don't want to." These are the women who are aggravatingly house-proud, who boast of never sitting down, who—if advised to stay in bed—say, "Oh, I couldn't rest for a minute." It is a state of diseased conscience. These are the people who love being martyrs, the trouble-borrowers. This temperament plus precipitating increase in anxiety leads to neurodermatitis. Two further examples follow.

Case 2.—A woman aged 29 was just such a personality. For two years she nursed her mother in her last illness. The following year she nursed her father in his last illness. After that she became depressed, unable to concentrate, and prone to attacks of weeping for no apparent reason. Then she began to scratch the back of her neck, producing the condition shown in Fig. 3.

Case 3.—A grinder aged 25 was injured two years previously when a grindstone exploded. He was afraid to return to his job, and developed a "nervous breakdown" and headaches. However, he did return, and in a few months began to scratch his right thigh. On examination he was obviously jumpy, had hyperidrosis of the hands, and admitted that he was scared stiff of his job. There was a large area of neurodermatitis on

his right thigh. He clearly understood the explanation of his symptoms, and recovered when his occupation was changed.

While localized neurodermatitis is more common in women, it does occur in men, and I have recently seen it in a boy of 6 who started to scratch when another child was born in the family.

In some cases the site of itching is in the region of an organic lesion, but in many there seems to be no such

localizing factor. In these cases the undue tendency to scratch is grafted on to one of the quite usual physiological scratching areas of the body. Very often the normal person scratches the back of the head when faced with a problem. Many of us, I am sure, have felt an itch in the region of the anus. Most people itch when they see skin patients at first. The severity of the itch depends on the degree of awareness or attention to the itch. The strength of the feeling will vary from time to time. To take an example from the pain sense: if we are prepared for a blow the resulting sensation will be painful. If we, however, sustain a blow on the football field it may not be noticed at the time and the bruise be found later.

In these individuals the sense of awareness of their own feelings is tuned up to a high pitch, and just as the effort-syndrome case can feel his heart beating so the individual with the tendency to neurodermatitis senses an irritation which the normal person would not. I have rather laboured this point because I feel it is so important to try to explain the transference of emotional tension into irritation.

Pruritus

Pruritus ani and vulvae forms a problem which can be explained reasonably well on those grounds. I think the types of cases of pruritus ani vary with the clinic to which they are sent, a higher proportion due to organic diseases being seen in the surgical and gynaecological out-patient departments. Certainly 50% of the cases seen in the skin out-patient department are of psychogenic origin, although a fair proportion of these patients did have some slight organic disease which drew their attention to the part.

Unlike the psychiatrists, I do not think that irritation of the anus and vulva always has some deep dark sexual significance, but both these areas are prone to trivial infections, tears in the mucosa, etc., which may start a pruritus if the individual is at the time facing some conflict in his or her life. Here I would like to give two brief examples.

Case 4.—A man aged 50, a hard-worked executive in a big works, had always had hyperidrosis of the natal cleft. During a spell of hot weather this caused some maceration of the skin. At that time he was overworked and worried and was suffering from insomnia. He found that, while lying in bed awake at night, he began to scratch the lesion. Ointments of various kinds gave him only temporary relief. He was an obsessional personality, ultra-clean, and when he came to see me he gave a detailed description of his anus and perineum which showed that he had been studying the matter closely. On examination the perianal skin showed lichenification and excoriation. Under

FIG. 3.—Case 2, showing localized patch of neurodermatitis on the neck.

treatment by reassurance and explanation, plus sedation, he ceased to have trouble. Here a trivial organic lesion in an obsessional personality under some strain became converted into a chronic pruritus ani.

Case 5.—An attractive and well-dressed woman aged 36 came to me complaining of pruritus vulvae. This dated from the time she found out that her husband had been unfaithful to her. Even though I could do nothing about her domestic life, an explanation of how the pruritus was caused, plus x-ray treatment and sedation, managed to cure her symptoms.

Occasionally one meets a case of localized pruritus where a search for a psychogenic factor appears completely negative. Sometimes these cases can be explained on a purely habit-scratching basis. These patients start to scratch a trivial organic lesion, and this becomes converted into a conditioned reflex rather similar to nail-biting. Any slight impulse from the site calls forth the desire to scratch, and eventually a patch of lichenified irritable skin results. An interruption of the vicious circle by local antipruritics and self-control by the patient may lead to a cure.

Lastly, there is a very small group—and I am sure that it is a very small group—who derive some erotic pleasure from scratching. In my experience this commonly occurs in young men, and the psychiatric explanation given for this is that the scratching is a form of masturbation. This group is incurable by the usual methods, and even with expert psychiatric treatment such as analysis success is unusual.

Eczema

Now to turn to the part played by the mind in eczema. All are familiar with the picture of infantile eczema which at a later stage develops into the flexural prurigo so classically described by Besnier in 1892. Here the constitutional tendency to eczema is inherited, and there is a close association between eczema and the other hypersensitive allergic states—asthma and hay-fever. All these diseases are evidence that the individual has inherited epithelium which is hypersensitive. The intelligence of the group is above average. Rogerson (1934) found an intelligence of 110–115 on the Binet scale. The normal average is 89.

The trigger which starts the eczema in infancy is usually organic. Cold winds, a strong soap, vaccination, an attack of gastro-enteritis, an allergic reaction to some food, a napkin rash, impetigo, and scabies can all precipitate an attack. Once the eczema has started the restless make-up of the child perpetuates the condition by rubbing and scratching. Taken at this stage the condition is primarily organic.

However, in many cases psychological factors are grafted on, and it is these which lead to the transition into Besnier's prurigo. In the majority of cases the parents are themselves anxious and excitable individuals, and the sight of their infant, often an only or a first-born child, tearing his skin to pieces and sleeping little at night completely demoralizes the home—as well it might. The mother tries ointment after ointment, fusses over the child's diet, prevents him playing with other children, and constantly attempts to stop him scratching. The child then becomes the pivot of the family and more and more demands care and attention, until he clings constantly to his mother. The continual thwarting of the child's activities leads to a rise in his mental tension. This leads to yet more irritation and scratching.

It is most striking that if the child is taken out of this environment he rapidly improves. As a generalization, all cases of infantile eczema can be cured quite rapidly in hospital or even in convalescent homes. That this might be due to removal from allergens is a criticism which has to be met in ascribing the trouble to psychogenic influence.

However, relapse may occur whilst in hospital after a visit from the parents.

Removal of the child from the home gives the distracted and sleepless parents a chance to recover. The prevention of a recurrence, which may happen within a few hours of his return home, depends on the treatment of the parents. They should be reassured that the disease is not fatal, that it is nothing to be ashamed of, and that, if they will develop a more detached attitude to the problem and allow the child to go his own way even if this means watching him scratch, it will recover. The child should be allowed outside activities and to take up a normal life as soon as possible. By this handling of cases the continuation of the condition into adult life can in most cases be prevented.

The tendency to eczema, however, lasts into adult life, and if this group have to face situations which increase emotional tension relapses will occur. I have one patient, a solicitor, who produces an outbreak of eczema after a week-end staying with his mother-in-law, whom he detests. Other cases recur if married life becomes impossible.

Rosacea

Rosacea is a permanent dilatation of the skin vessels of the nose, cheeks, forehead, and chin, associated with a papular and pustular eruption which is a sequel to the chronic dilatation. This dilatation may be caused in various ways. Exposure to wind and weather, dyspepsia, ovarian disease, and exposure to heat as in furnace-workers are responsible in some cases, but by far the commonest cause is reflex blushing of emotional origin. After many years of emotional blushing the vessels become permanently dilated, and later the papules and pustules form. At a later stage the eyes may be involved in the process, with the onset of keratitis.

Rosacea is essentially a dynamic process, exacerbation and remission occurring in a very short time. Exposure to a hot room, drinking hot drinks, and acute worry can all produce exacerbation. Klaber and Wittkower (1939) found that 35 out of 50 rosacea patients described themselves as quiet, reserved, and serious-minded. As children they disliked parties and meeting strangers. They were bashful, and any attempt to force them to appear in solo performances of any kind filled them with terror. They were obstinate and sullen if attacked. Rarely did they display any temper. He described the condition as showing undue social anxiety. With the background of this personality any acute emotional crisis is apt to produce rosacea. A typical example is the following:

The patient was a female shop assistant aged 35 who described herself as shy and who blushed easily on speaking to anyone. She was solitary, loved reading, had only one or two women friends, and hated meeting strangers. A year before I saw her she had had the first affair of her life with a married man. This she ended because she felt so ashamed. She was very upset at giving up this friendship, and lost interest in life. Shortly afterwards rosacea developed.

Here one can see the personality and the precipitating crisis associated with shame.

Group 3

The third group of skin conditions in which the mind plays a part are those in which only occasionally is the mental side a factor. In this group are included skin reactions such as urticaria, seborrhoeic dermatitis and psoriasis, hyperidrosis, cheiropompholyx, and alopecia areata.

So far I have been unable to produce scientific evidence that the mind can produce a skin lesion. It has all been the "I had a case" evidence. In dealing with urticaria one is on firmer ground. Grant, Pearson, and Comeau

(1936) described a series of cases of urticaria in which attacks were brought on by emotion, heat, and cold. After the most exhaustive tests they proved fairly conclusively that the urticarial reaction in these patients depended on the peripheral nerves being intact; they believed the stimulus to be along these nerves and to be of cholinergic parasympathetic type.

The mechanism was that acetylcholine was released at the nerve-endings, and that this led to the formation of histamine, which produced the urticaria. In these cases attacks could be brought on by injecting carbachol and aborted by giving atropine. Peculiarly enough, some research done in 1947 on the nettle proved that a nettle sting acted not by releasing formic acid but by injecting acetylcholine and histamine, so that even the naturally produced nettle-rash falls into line with Grant, Pearson, and Comeau's work.

Further confirmation of the power of the mind to produced urticaria and even bleeding was given by Moody (1948), who described urticarial reactions occurring in a patient undergoing narco-analysis and reliving incidents of her past, in which she had been beaten by a sadistic parent. On recalling particular incidents, urticarial weals appeared on the original sites of the injuries.

The easiest way to regard seborrhoeic dermatitis and psoriasis is to look on them as skin reactions which are inborn and which may be precipitated in many ways—by trauma, by infection, and occasionally by mental stress. It was not uncommon to see men who on entering the Services developed seborrhoeic dermatitis which lasted all the time until they were invalided and then cleared rapidly without treatment. Psoriasis occasionally becomes generalized after emotional shocks.

The onset of alopecia areata is often related to unhappiness, though in a great many cases, particularly in children, no psychogenic factor can be discovered.

Just how much bearing the mind has on the onset of allergic and contact dermatitis it is difficult to assess. I feel that in some cases the hyperexcitability of the tissues, which allows them to become sensitized, may well be a result of anxiety. I remember the case of a woman who was unhappily married to a husband of another religion. She hated going to gatherings of his relatives, and on these occasions her face became flushed and irritable. I thought at first that the eruption was entirely psychogenic, but to make sure I patch-tested her to her lipstick, which she also applied to her cheeks as rouge. She gave a violently positive reaction, and cessation of its use led to clearing of the rash. She had been using the lipstick for years, and it may well be that unless she had been acutely unhappy she would not have become sensitized.

Local hyperhidrosis is often a result of chronic anxiety. Cases occurred more often in the Services than in civilian practice.

Cheirpompholyx is a dangerous subject to discuss, as the causes are innumerable, but now and again one comes across a case with an obvious psychogenic background which can be cured by reassurance and explanation. Any case of cheirpompholyx for which no other cause can be found should be investigated for the presence of psychogenic influences.

I have been most impressed by the stories obtained from these patients with psychogenic backgrounds. It is not necessary to make up fears and difficult situations for them. Usually their life situations are such that it is not surprising to find them breaking down in one way or another.

Treatment

The most important feature is to realize that the handling of the psychodermatoses differs in no way from that of

other psychosomatic disease. These patients are constitutionally less able to face life's problems than the average run of humanity, and are not persons with only an inflamed patch of skin.

A firm but kindly sympathetic approach is necessary, and it takes time to extract the life story and the salient problems which have led up to the onset of the dermatosis. It is impossible to gain the patients' confidence with other people—particularly relatives—present, and it may not be until the second or third interview that they will unburden themselves.

After the diagnosis has been made—and I hope that I have shown in what types of cases the psychogenic causes may be suspected—symptomatic treatment may be started. General sedation with small doses of phenobarbitone, local antipruritics—but here I must stress the need for simple agents not likely to sensitize the skin—and x-ray therapy, which is the most powerful antipruritic, will all help to alleviate the symptoms.

After the first few days, when the irritation lessens, the patient will accept more readily the doctor's reassurance that he knows what is the matter, and will be prepared to listen to a simple explanation of how a tense nervous state has led to the present condition. Even if the social conditions and environment remain impossible, as so many of them do, symptoms can be relieved.

However, relapse is likely unless something more can be done. In Sheffield we have an almoner whose main duty is solving the problems which beset these patients. She helps by arranging holidays for the housewife who has reached cracking point and home helps for those who cannot leave small infants. Sometimes she can find other accommodation for those who have to live with "in-laws," and alternative occupations for those who have congenial work. She obtains legal advice for those for whom a divorce seems the only way out, and, above all, she remains a friend to whom those in trouble can come and pour out their day-to-day worries.

In the short time that it has been in existence the almoner service has produced more permanent cures than all our ointments and magic rays. However, the person who should be really fitted to carry out the correct treatment is the family doctor. He has the facts of the family life at his finger-tips, we have to drag them out painfully. It is the family doctor who, if he can recognize that the skin condition which has brought Mrs. X to his surgery is really repressed indignation because she has an impossible husband, is the best person to give reassurance and advice.

There are, of course, incurables—the patients who trade on illness, those not intelligent enough to listen to advice and who cannot gain insight into their problems, and those who are so constitutionally inadequate that no one can help them. However, the incurables form only a small percentage, and I hope I have made my point that the psychodermatoses are a very real group among skin diseases and that a great deal can be done for those suffering from them.

TREATMENT OF SKIN LESIONS CAUSED BY MUSTARD GAS

BY

D. C. SINCLAIR, M.A., M.D.

(From the Department of Anatomy, University of Oxford)

On the basis of clinical observations Chiesman (1944) and Davis (1944) published some general remarks on the treatment of skin burns caused by mustard gas. However, no study of the results of treatment under field conditions has appeared since the reports of the 1914-18 war casualties (Soltau and Elliott, 1923). The present paper deals with the treatment of a series of men exposed to mustard gas in the Tropics while living under an approximation to field conditions.

Material and Methods

Between 1943 and 1945 observations were made on 438 healthy young men exposed to mustard gas under tropical conditions—320 were exposed to mustard vapour and 118 to contamination by liquid mustard. Dressings were changed daily, and no attempt was made to maintain strict asepsis. The materials and methods used for treatment were purposely restricted to those readily available to any medical officer in the field. All applications were made on gauze or plain surgical lint and were kept in place by a bandage, since adhesive plaster did not adhere properly and gave rise to local irritation.

The lesions treated ranged from small superficial abrasion-like areas to large deep ulcers. Of the vapour cases 75 suffered nothing more than an erythema, and in only 154 of the remaining 245 did breaches of the continuity of the skin develop (Table I). Raw surfaces occurred

TABLE I.—Lesions Available for Treatment

Type of Case	Volunteers			Regional Raw Surfaces		
	No. Exposed	No. Treated	No. with Breaches of Skin	Total	No. Treated	No. of "Whole-thickness" Burns
Vapour ..	320	104	154	495	234	1
Liquid ..	118	83	79	254	68	18
Total ..	438	187	233	749	302	19

in 79 men exposed to liquid mustard, and 18 "whole-thickness" burns were distributed among nine of these men. The term "regional raw surfaces" in Table I refers to arbitrarily defined regions (Sinclair, 1948b) in which one or more breaches of surface continuity occurred, without regard to the number of these breaches. It will be noted that only 302 out of 749 regional raw surfaces received treatment: this figure includes all the whole-thickness burns and most of those lesions occurring in the 30 subjects who were admitted to hospital. In the remaining men 447 unselected regional raw surfaces received no treatment of any kind beyond the evacuation of vesicles, and were used as controls.

The irregularity and delay in development of mustard burns (Sinclair, 1948b) make it impossible to evaluate the effect of treatment unless the development of an exactly similar untreated burn in the same area of the opposite side of the same man can be observed. This requirement is seldom satisfied in mustard-gas burns. Further, in this series strict supervision of treatment was impossible. For these reasons no valid comparison can be made of the effect of the various treatments used on the development, course, and healing of the burns. However, sufficient

detailed information was obtained to enable a general clinical appraisal of treatment to be made.

General Treatment

Pain was controlled by acetylsalicylic acid, phenacetin, bromide and chloral, or hyoscyne hydrobromide. In the worst cases, particularly those with severe burns of the genitalia, $\frac{1}{4}$ gr. (16 mg.) of morphine three times daily was necessary.

The treatment of systemic poisoning (Sinclair, 1948a) was purely symptomatic and unsatisfactory. Nausea and vomiting were unrelieved by either alkaline mixtures or sedatives. Alkali was, however, useful in alleviating abdominal pain when given in full doses after meals. The typical severe headache was unaffected by acetylsalicylic acid, phenacetin, and ergotamine.

Education formed a very necessary part of the treatment, owing to the prevalence of superstitious ideas about mustard gas. In two cases anxiety states developed, necessitating continued reassurance.

Local Treatment

Desquamation.—The onset of desquamation or exfoliation in any part was usually accompanied by considerable irritation, itching, and stinging pain. These symptoms were greatly aggravated by scratching, which took place in many cases while the men were asleep. For this reason it was occasionally necessary to apply a dressing to areas of severe desquamation. The treatment of choice was the ununction of zinc cream (A.P.F.) (anhydrous wool fat, 3; olive oil, 3; zinc oxide, 4; lime water, 4).

Raw Surfaces.—These were the result either of desquamation or of vesication. Vesicles were swabbed with weak "dettol" solution and pricked with a sterile needle to collapse down the vesicle roof. Subsequent re-evacuation was practised as necessary. Any blisters 1 cm.² or less in floor area were left without treatment of any kind (Table II). The treatments used for raw surfaces included the

TABLE II.—Liquid Burns: Treatment of Raw Surfaces by Area

Approximate Size of Raw Surface	No. of Lesions	No. Treated	Percentage Treated
0-1 cm. ²	81	0	0
1-10 cm. ²	192	19	10
10-100 cm. ²	55	36	65
Over 100 cm. ²	16	13	81

following: amyl salicylate, sulphonamide preparations (sulphanilamide powder and sulphathiazole powder), greasy preparations (zinc cream (A.P.F.), vaselined gauze, and acriflavine emulsion (B.P.)), and dyes (triple dye and 1 in 1,000 aqueous acriflavine).

Amyl Salicylate.—The drawbacks of amyl salicylate as a treatment for mustard burns are several. It is too irritant to apply to the scrotum by the ordinary method (Ministry of Health, 1942; Chiesman, 1944), and in vapour cases the scrotum is the region most commonly affected (Sinclair, 1948b). It cannot be applied to any area for longer than three or four days without causing pain (Ministry of Health, 1942; Cullumbine and Sinclair, 1942), it has an objectionable and persistent smell (Stewart, 1937), and it clings to the fingers, dressings, and bedclothes. It does not bring about more rapid healing (Cullumbine and Sinclair, 1942; Davis, 1944), and in the present series burns treated with it tended to be rather more painful than burns treated by other methods. "Hypersensitivity" to amyl salicylate has been reported (Stewart, 1937). In consequence of these objections, amyl salicylate has now fallen into disuse (War Office, 1944).

Sulphonamide Preparations.—In view of the effect of absorbed mustard derivatives in depressing leucocyte formation it is clear that the application of sulphonamides to any large mustard burn calls for considerable caution (Chiesman, 1944; Sinclair,

1944). Many lesions treated with local sulphonamides in this series became slightly irritated and inflamed; it should, however, be noted that micronized sulphonamides were not available.

Greasy Preparations.—The outstanding feature of this group of treatments was the comfort of the lesions so treated. Zinc cream (A.P.F.) was the most successful and, under local conditions, the most readily available in bulk. These preparations also enabled quick and relatively painless changes of dressing to be made. This factor was particularly important in the case of burns of the genitalia.

Dyes.—Triple dye was extensively used for small raw surfaces. The dye was applied as a paint, two or three coats being given at each dressing, and the burn was then left completely uncovered. Patients preferred this treatment to the inconvenience of a dressing and bandage, and burns so treated were very comfortable and quickly ceased discharging. It should be noted that no attempt was made to tan the raw surface. Owing to the difficulty of obtaining strict asepsis at the time of application, tanning should be used sparingly under field conditions (Cullumbine and Sinclair, 1942; War Office, 1944; Chiesman, 1944; Davis, 1944). Acriflavine solution, 1 in 1,000 in water, was also used, but was not nearly so satisfactory.

Untreated Controls.—The untreated lesions appeared to be as comfortable and certainly healed as rapidly as the treated burns of comparable severity. The pressure and friction of clothing, except in the case of burns of the scrotum, did not give rise to undue discomfort, and the lesions dried up rather more quickly than in cases where treatment was applied.

Treatment of Genital Lesions.—For lesions of the genitalia the most comfortable and convenient application was vaselined gauze. In hospital cases a daily tepid saline bath also relieved pain and irritation to a marked degree. All dressings applied to burns of the scrotum in ambulant cases were conveniently retained in position by an elastic suspensory bandage. The value of these bandages cannot be over-emphasized. The elastic support relieved the tension and dragging pain resulting from the presence of oedema fluid, and the friction of the clothing over the large, tender, raw scrotum was much reduced. Men with extensive deep burns, sometimes involving half the scrotal surface, were thus enabled to remain ambulant.

Complications

Dysuria.—Four cases with extensive raw surfaces on the glans penis suffered from intensely painful micturition, which was to a certain extent relieved by coating the burn heavily with vaseline. Ulceration of the meatus (Mackintosh, 1920) did not occur in this series.

Priapism.—In two vapour cases in which the penis was extensively burned, frequent, prolonged, and extremely painful priapism occurred, usually at night, during the first two weeks of treatment. Large doses of bromide and other sedatives were without prophylactic effect, and the only measure which afforded relief was an immediate cold saline bath.

Sepsis.—The presence of infection in any lesion was assessed as "slight" (some seropurulent discharge but no other local signs), "moderate" (frank pus present), or "severe" (frank pus, with local tenderness, inflammation of surrounding skin, and regional adenitis). The results of this classification are seen in Table III. The overall regional

infection rate was 32 out of 749 (4.3%), and the infection rate was higher (9.4%) in the case of liquid burns than in the vapour series (1.6%). Many of these infections were, however, of very little clinical importance, and Table III shows that in only 10 (1.3%) cases could infection be described as more than trivial. It is also interesting to note that sepsis became established while local treatment was being applied in 17 out of the 302 cases which received treatment—an infection rate of 5.6%. The infection rate in cases receiving no treatment was 3.4%.

Adenitis.—In four infected cases there was a regional adenitis throughout the period of infection. In eight other vapour cases, however, a regional adenitis appeared without any sign of local inflammation. The affected glands were rubbery, discrete, and not tender. These cases have not been considered under the heading of sepsis, since the absence of tenderness and pain, of any constitutional symptoms, of lymphangitis, and of any clinical evidence of infection in the drainage area was a noticeable feature.

Sloughs.—In the series of liquid burns small sloughs appeared in various situations in two subjects but separated rapidly; they were accompanied by slight sepsis. In the vapour series, however, it was a striking fact that slough formation, which occurred in six men, was confined to the prepuce. In the worst case gross annular sloughing occurred on the fifteenth day and did not completely separate until the thirtieth day.

Discussion

The mustard burn is not a specific and peculiar lesion, but is simply the response of the skin to a slowly acting tissue injurant (Sinclair, 1948b). It is therefore most unlikely that any specific treatment will be found for established mustard lesions, and in consequence it is permissible to treat such burns exactly as thermal burns, according to the personal preference of the operator. Koontz (1944), as a result of animal studies, concludes that "there is no major difference, either qualitative or quantitative, between heat burns and mustard burns of equal intensity," and points out that the same methods of treatment should therefore be applicable to both. Davis (1944) concludes that "almost any of the generally accepted techniques of burn treatment" may be used for mustard burns in man. Insufficient attention has been paid in the past to difficulties of assessment, and specific treatments—for example, amyl salicylate—have been recommended for mustard burns on inadequate grounds.

The healing-time of mustard burns is not greatly influenced by the type of therapeutic agent employed (Cullumbine and Sinclair, 1942; Davis, 1944), and there is no evidence that any of the treatments applied in the present series achieved significantly better results than could be expected in the absence of local treatment. There remain, however, the factors of comfort, ease of application, availability, cost, etc., to be considered. Bearing in mind these considerations, it may be said that for the irritation caused by desquamation of the skin zinc cream (A.P.F.) was useful. For the raw surfaces, which constituted the most important feature of these cases, zinc cream and vaselined gauze were the best of the treatments investigated, while triple dye paint was extremely useful for minor lesions of this type and when a dressing could not conveniently be retained in position. For scrotal burns the suspensory bandage was invaluable, and in hospital cases saline baths were found very comforting.

There is a widespread opinion that mustard burns are especially liable to infection. Chiesman (1944) states that "they are slow to heal, prone to sepsis, and respond badly to any form of tanning." There is, however, no evidence to show that a series of human experimental thermal burns

TABLE III.—Incidence of Sepsis

Type of Case	No. of Regional Raw Surfaces	No. of Regional Raw Surfaces Infected				No. of Infections Classified as More than Trivial
		Slight	Moderate	Severe	Total	
Vapour ..	495	6	1	1	8	2
Liquid ..	254	16	5	3	24	8
Total ..	749	22	6	4	32	10

is any less liable to infection than a series of mustard burns of similar intensity and distribution. Nor has it been shown that under these circumstances the thermal burns would heal any more quickly than the mustard burns. Until such an investigation has been made it is begging the question to hold that the mustard burn is specially prone to sepsis and slow to heal.

Summary

An account is given of some observations made on the treatment of a series of skin burns caused by mustard gas under tropical conditions. It was not possible to make any accurately controlled investigation, but it appeared that no local treatment achieved better results than could be expected in untreated burns.

On the basis of factors such as comfort, convenience, expense, etc., zinc cream (A.P.F.) and vaselined gauze were the best of the treatments investigated for breaches of skin continuity. Triple dye, used as a paint, was valuable for treating small superficial lesions.

Suspensory bandages were of great value in the treatment of scrotal burns.

There was a comparatively low incidence of sepsis, in spite of the fact that the burns were treated under an approximation to field conditions.

There is no reason to suppose that mustard burns behave any differently from thermal burns in regard to their healing or liability to infection.

The kindness of the Australian Chemical Defence Board in permitting publication of the work carried out under its direction is gratefully acknowledged. Permission to publish has also been received from the chief scientist, Ministry of Supply.

I should like also to record my indebtedness to Mr. J. W. Legge and to the numerous colleagues who assisted in the application, supervision, and assessment of the treatments investigated.

INCIDENCE OF DIABETES MELLITUS IN CHILDREN AND NEED FOR HOSTELS

BY

P. HENDERSON, M.D., D.P.H.

Medical Officer, Ministry of Education

In an annotation in the *British Medical Journal* of Feb. 7, 1948 (p. 261), it was stated that "the incidence of diabetes is unknown, although some idea of its prevalence can be obtained from the mortality returns." Lawrence (1944) wrote: "Diabetes has been recorded in infants of a few months, but is very rare under 6 years of age." In America several surveys have been made. Joslin (1946) quoted the findings of the National Health Survey of 2,500,000 persons, carried out under the auspices of the United States Public Health Service in 1935-6, when it was found that in the age group 0-14 years one child in every 2,500 was a diabetic: the incidence was the same for boys and girls, and

for all age groups was 0.37% of the total population (adults and children). Wilkerson and Krall (1947) reported the results of a thorough investigation into the incidence of the disease in Oxford, Mass. Of the 4,983 inhabitants 3,516 had their blood and urine tested. After allowing for the 29.4% of the town's citizens who had not been tested it was estimated that 1.7% of the population had diabetes.

Joslin (1946) also mentioned that the mortality rate from diabetes in the U.S.A. in 1943 was 27.1 per 100,000 of the population; in England and Wales in 1944 it was 9.6 per 100,000. The much lower diabetes death rate in England and Wales supports the view that the incidence of the disease is considerably less in these islands than it is in the U.S.A.

Present Investigation

In the absence of up-to-date information about the extent of diabetes in children in this country it was decided to make a survey, during the period February-June, 1948, in the following areas: Bristol, Birmingham, Birkenhead, Wallasey, Liverpool, Bootle, Salford, Manchester, Bradford, Leeds, Newcastle-upon-Tyne, Sheffield, Norwich, Ipswich, Great Yarmouth, Cambridge, Norfolk, Isle of Ely, Cambridgeshire, and East and West Suffolk.

All the school medical officers (who were, with one exception, also medical officers of health), the professors of child health, and all the hospitals in these areas likely to have child patients with diabetes were approached for information. The physicians of 32 hospitals co-operated: only one hospital ignored the requests made to it.

All lists of children supplied by the hospitals were cross-checked against the lists held by the school medical officers and the medical officers of infant welfare clinics to avoid duplication of names and to ensure that children not living in these areas were excluded, since many of the hospitals had patients from a wide countryside and from districts not included in this survey.

Size of Population Sampled.—The 16 cities and towns and the five counties selected for this inquiry had a total child population under 16 years of age of 1,307,000; there were about 750,000 school-children, being between one-sixth and one-seventh of the total school population of England and Wales: the rate was broadly similar for urban and rural children. Table I gives the number and age distribution of the children.

TABLE I.—Age Distribution

Age	Urban	Mainly Rural	Total
0-4 ..	470,000	70,000	540,000
5-9 ..	386,000	50,000	436,000
10-15 ..	290,000	41,000	331,000
Total	1,146,000	161,000	1,307,000

TABLE II.—Incidence of Diabetes in Sample Population

Age	No. of Children with Diabetes		
	Boys	Girls	Total
0-4 ..	1	2	3 (1 in 180,000)
5-9 ..	28	26	56 (1 in 8,000)
10-15 ..	70	54	124 (1 in 3,000)
Total ..	99	84	183 (1 in 7,000)

Of the 180 school-children (Table II) 145 (1 in 5,000) lived in urban areas, and 35 (1 in 3,000) lived in mainly rural areas. If the sample can be taken as representative of the child population then the estimated number of diabetic school-children in England and Wales is 1,200 (1 in every 4,000-5,000).

Number of Diabetic Children in Need of Hostel Treatment

Several of the physicians who provided information expressed the opinion that diabetic children should remain at home and not be sent to hostels. One expressed the view of several when he wrote: "All diabetic children should be brought up to lead normal lives with other children, and I find that this is possible with nearly all of them." Another wrote: "I do feel that on the whole children suffer more by being moved from their home environment than they gain by going to live in a hostel." Others, however, considered that hostels were essential for a small minority of diabetic children; one gave the history of a girl aged 12 who spent most of her life in two hospitals, having been admitted to each alternately in diabetic coma. Another child, who was not receiving the treatment prescribed, was found to have a mother who did not understand the instructions given to her as "she was deaf and otherwise peculiar."

An interesting finding was the greater demand for hostels for children from rural areas. Table III gives the number and age distribution of the children in the sample population who were recommended for admission to a hostel.

TABLE III.—Children Recommended for Admission to Hostel

Age	Boys	Girls	Total
0-4	1	—	1 (1 in 500,000)
5-9	4	3	7 (1 in 60,000)
10-15	7	6	13 (1 in 25,000)
Total	12	9	21 (1 in 60,000)

Of these 21 children seven were already in a hostel or hospital. Thus in this series one diabetic child in every nine was recommended for a hostel. On these figures there is need for hostels for at least 130 diabetic children in England and Wales. The survey also showed that in mainly rural areas one school-child in every 13,000, and in urban areas one in every 50,000, should be in a hostel for diabetics. The main reason for the greater need for hostels for rural children is the lack of specialist treatment facilities within easy reach of their homes. The difference in the incidence of diabetes between the urban and rural population was not sufficient to explain the great disparity in the proportion of school-children recommended for a hostel in these two groups.

Since September, 1939, the London Education Authority has maintained a diabetic unit for 60 boys and girls at its large residential school at Hutton, Essex. On the average, only about 16 of the 60 are London children, giving a rate of one child per 20,000 of the London school population. In view of the effects of the war on London homes it was to be expected that more London diabetic children would require hostel accommodation than children in provincial cities and towns. Of the 16 London children living in Hutton during the period of this inquiry eight were fatherless, motherless, or had parents who were separated.

Allowing for the higher rate of hostel provision required for London and rural children, rather more than 130 places are needed. On the basis of the present investigation hostels for 130-150 diabetic children should be provided for a school population of about 5,000,000. In addition to the 60 places at Hutton a second hostel for 30 diabetic boys and girls was opened at Deal by the Church of England Children's Society in January, 1949. There are prospects of a third hostel for about 30 children being opened in 1949.

Anyone having doubts about the value of a hostel for a minority of diabetic children should visit Hutton. There the boys and girls are taught the diabetic way of life; they test their own urine and, under supervision, inject their own

insulin. They are supervised by a trained nursing staff, and a specialist physician visits fortnightly. They lead as free and as normal a life as any child in a public boarding school. Their out-of-school life is full of variety. They take part in any physical activity or game that they choose and they all learn to swim in the school swimming-bath. Most are allowed home for the usual school holidays. In early summer they all go to camp for a fortnight at the seaside. They grow up into self-reliant men and women, fully capable of leading happy and useful lives. Unfortunately, some parents are so foolish that they prematurely withdraw their children from the hostel. Whittaker (1948) reported the deaths of five children who had been removed from Hutton against advice. And in this country in 1945, according to the Registrar-General (1945), 51 children under 15 years of age died from diabetes. These melancholy figures represent a yearly wastage of young lives that could be reduced considerably if adequate hostel facilities were available.

Summary

Of 1,307,000 children under 16 years of age (being from one-sixth to one-seventh of the total child population under 16 years of age in England and Wales) living in 16 English cities and towns and five counties, 183 (1 in 7,000) were known to have diabetes. Of the 180 school-children, 145 (1 in 5,000) lived in urban areas and 35 (1 in 3,000) in mainly rural areas. An incidence rate of 1 in 7,000 is only about one-third of that (1 in 2,500) found in 1935-6 in the survey sponsored by the U.S. Public Health Service.

The incidence rose sharply from 1 in 180,000 for children under 5 years to 1 in 8,000 for children 5-9 years and to 1 in 3,000 for children aged 10-15 years.

About one diabetic child in nine was recommended for a hostel. In the mainly rural areas one school-child in every 13,000, and in the cities and towns one in every 50,000, was considered suitable for a hostel; in London the rate was 1 in 20,000. The higher London figure was at least partly due to the effects of the last war, since half the total number of the London children were fatherless, motherless, or had parents who were separated. The high rural rate was mainly due to the absence of specialist treatment facilities within easy reach of the children's homes.

Allowing for the greater need for hostels for diabetic children in London and the rural areas, this survey revealed the need for hostels for 130-150 children under 16 years of age in England and Wales with a school population of about 5,000,000. At the time of this investigation there was hostel accommodation for only 60 diabetic children in the London County Council's School at Hutton. A second hostel for 30 children was opened in Deal in January, 1949, by the Church of England Children's Society, and there are prospects of a third hostel being opened during 1949.

I gratefully acknowledge the help given to me by the school medical officers of the areas mentioned in this article and by the professors of child health, physicians, almoners, and secretaries of the hospitals in these areas who so willingly supplied me with information.

The Minister of Health and Local Government of Northern Ireland stated recently that plans are on foot to provide this year 200 additional beds for tuberculosis sufferers in Northern Ireland. The Minister added that he would further consider a suggestion that the Government should make representations to the proper authorities towards making arrangements for the treatment in Swiss hospitals of patients suffering from tuberculosis in view of the present shortage of beds in Northern Ireland.

SIMULTANEOUS EMBOLISM IN BOTH ARMS

BY

J. V. FIDDIAN, M.D.

Surgeon to the District Infirmary, Ashton-under-Lyne

We read a good deal about arterial embolism of the limbs these days, but it must be a somewhat rare occurrence, for I have had to wait twenty-nine years as a surgeon at a hospital of two hundred mainly surgical beds to see my first case. But, as if to make up for this delay, my case when it did appear presented me with simultaneous embolism of both axillary arteries. How rare this is I have not been able to discover. The surgical literature at my disposal does not record a single case.

Case History

The patient, a railway worker aged 69, had a Syme's amputation of his right foot in 1915 after an accident on the line. The stump has served him well, his only complaint being the usual one with Syme's amputations—that the foot tended to work round in internal rotation so that the toe struck his other foot in walking.

Four months before admission to hospital an ulcer developed over the external malleolus. It was very painful and gradually extended in spite of rest in bed, "elastoplast" bandaging, ultra-violet irradiation, and a variety of dressings, including penicillin. On admission he was seen to be a healthy-looking man. His past health record was good: he had not attended his panel doctor for twenty years. His blood pressure was 130/80, his urine was free from sugar and albumin, and his Wassermann reaction was negative. The radial artery was thickened, however, and capillary circulation at the extremities was slower than normal. A diagnosis of arteriosclerotic circulatory defect was made, and he was advised to have the limb amputated below the knee.

On June 24, 1947, I amputated the leg 4 in. (10 cm.) below the tibial tubercle under thiopentone-gas-oxygen-ether given by Dr. John Moore. The reduced size of the lumen of the tibial arteries was noticed. Healing was retarded by the poor nutrition of the flaps. There was no inflammatory or febrile reaction, but when the stitches were removed on the twelfth day there was considerable failure of union. Healing proceeded very gradually. His general condition was good and he was free from pain. He got about the ward in a wheeled chair and later on crutches.

On Sept. 12, at 5.30 p.m., he went out on crutches to the toilet and while there felt tingling in both wrists and "came over faint." He walked back to his bed on his crutches with assistance. The tingling increased and numbness developed in his hands. A little later he complained of pain in both upper arms. When I saw him at 6.30 he was not greatly distressed, but said the use had gone out of both his arms. They were cold and blue. He could move his fingers slightly. No radial pulse could be felt on either side. Pulsation was present in the brachial artery to about 1 in. (2.5 cm.) above the humeral artery. There was no pulsation on the right below the axilla, and the third part of the axillary artery was pulsating.

At 7.30, using brachial plexus block analgesia, I exposed the site of the embolism in the right axillary artery and, controlling the pulsating artery by a loop of tape held up by a haemostat, incised the non-pulsating area immediately below. A clot some 3 in. (7.5 cm.) long was extracted and a small rubber catheter was passed down the artery and suction applied by a syringe; in this way several more pieces of clot were obtained, and a stream of 2% citrate solution was injected. The arm was then massaged in an upward direction and finally the artery was closed by a single continuous suture of No. 2 nylon with a very fine needle. The adventitia was stripped from the artery above the incision and the tape was then relaxed. Pulsation could immediately be felt at the elbow. Others in the theatre said they could feel the radial pulse. The wound was closed and dressed and the patient given a cup of tea and a

cigarette. After an interval of half an hour a similar proceeding was carried out at the lower end of the left brachia artery. A bifurcated clot which had filled the lower part of the brachial artery and the upper 2 in. (5 cm.) of both radial and ulnar arteries was extracted with forceps. Directly the artery was closed and the tape released full volume was restored in the radial pulse.

In view of the different fate which befell the arms I reviewed my technique to discover if possible what determined failure on the right and success on the left. Differences of procedure were as follows:

Right	Left
Operation two hours earlier	Operation two hours later
Incision in non-pulsating artery	Incision in pulsating artery
Denudation of vessel not so satisfactorily performed	Very thorough denudation of vessel
Injection of heparin had not been given, through delay in obtaining it.	Injection of heparin before starting operation.

Whatever the cause, and I am inclined to blame the inadequate denervation of the right artery, the subsequent fate of the two limbs was strikingly different. By the next morning the left arm was of normal appearance and all movements of the wrist and fingers could be obtained, and with considerable power. Radial pulsation was of normal volume. Subsequent progress was uneventful. The wound healed by first intention and the arm has remained in full function ever since. The right arm was discoloured and cold from the elbow downwards. Pulsation could be felt in the brachial artery down to the elbow. Capillary circulation could be shown to about 2 in. (5 cm.) below the elbow. No radial pulse could be felt. Heparin was pushed, and the arm was kept exposed to cool air.

A masseuse visited him several times a day to give light effleurage and the skin was kept as sterile as possible by rubbing with spirit. 125,000 units of penicillin were given thrice daily. The colour remained the blue of a bruise and no improvement in capillary circulation could be seen, but the patient said he could feel life in the forearm nearly to the wrist and could make some slight movement of one or two fingers. After nineteen days massive vesication appeared and I amputated at the lower third of the upper arm. He has made a good recovery, uses his left arm normally, and is busy trying to walk on his new artificial leg.

KETONURIA IN A CHILD WITH CIRRHOSIS OF THE LIVER

BY

G. T. RUTHERFOORD, M.B., B.S.

Late Resident Medical Officer, Southampton Children's Hospital

The interest of the following case lies in the fact that a child with cirrhosis of the liver had ketonuria as the chief sign. The cirrhosis was unsuspected during life. The initial illness, characterized by constipation and abdominal distension, was apparently not related to the liver disease.

Case Report

In November, 1945, a boy aged 2½ was admitted to the Southampton Children's Hospital with severe constipation and abdominal distension. The condition was diagnosed as Hirschsprung's disease. A barium enema shortly after admission revealed a mild degree of megacolon; another, two months later, showed no abnormality. During the next eighteen months the boy was seen regularly in the out-patient department. He remained in fair health, though persistent constipation necessitated the regular use of aperients and occasional enemata.

In January, 1948, when aged 4 years 10 months, he was re-admitted. He had been well until the day before admission when he had had a convulsion. A further convulsion occurred a few hours later, this being followed by a third on the morning of admission, since when he had been comatose. On examination he was found to be unconscious, slightly cyanosed, and

breathing rapidly and deeply. There was slight neck rigidity. The abdomen was not distended, and rectal examination was negative. The urine contained a large quantity of acetone. Gerhardt's test for diacetic acid was also positive. Sugar was absent. Consciousness returned a few hours after admission. Next day a purulent nasal discharge, pharyngitis, and cough were noted. Radiographs of the chest and examination of the cerebrospinal fluid revealed no abnormality. The blood-sugar level was not estimated. A few days later, following a course of a sulphonamide, recovery appeared to be complete.

After leaving hospital he was noticed always to be listless and easily tired, though well enough to attend school for some weeks. In April, 1948, he was in bed for a week with pyrexia, vomiting, and diarrhoea. His parents remarked that at times he became excessively thirsty, and had an inordinate liking for salt. Apart from a distaste for sweet things, his appetite, though poor, was normal.

In July, 1948, he was again readmitted. A convulsion, preceded by severe abdominal pain, had begun a few hours previously, since when he had been unconscious. On examination he was found to be unconscious and slightly cyanosed, but was breathing normally. No other abnormal physical signs were elicited. The urine contained large quantities of acetone and diacetic acid. No sugar was detected. A sample of blood (taken on admission) showed a blood-sugar level of 35 mg. per 100 ml. A few hours after admission he was conscious and rational and was drinking glucose-water freely. His condition, however, deteriorated. During the night there were two convulsions, and vomiting became frequent. Twenty-four hours after admission he died in a third convulsion.

Post-mortem Findings.—Development normal; nutrition fair; no jaundice. **Lungs.**—Bulky and emphysematous; distended with air anteriorly and cover heart; some petechial haemorrhages on posterior surface; normal appearance on section. **Heart.**—Many large subpericardial haemorrhages. **Spleen.**—Much enlarged; weight, 4½ oz. (135 g.); Malpighian bodies prominent. **Liver.**—Small; weight, 1 lb. 4½ oz. (580 g.); surface coarsely roughened; on section, coarse cirrhosis and early nodular hypertrophy. **Pancreas.**—Normal. **Kidneys.**—Cortex swollen, showing toxic changes. **Colon and other organs.**—Normal.

Histology.—**Liver.**—Portal cirrhosis of nodular type; the portal tracts show excess of fibrous tissue, and heavy infiltration by lymphocytes and a few eosinophils; the liver lobules are very irregular in size and shape; the sinusoids are full of red cells, indicating acute passive congestion. **Pancreas.**—Normal. **Kidneys.**—Marked congestion of the medulla and cortex and of glomeruli; cloudy swelling of tubules.

Comment

It may be inferred that the first attack of convulsions, which ceased spontaneously and did not recur for five months, was hypoglycaemic in origin and was precipitated by a mild infection of the upper respiratory tract.

The low level of the blood sugar was no doubt due to the liver disease (Hartmann and Jaudon, 1937), and was probably the cause of death. Hypoglycaemia has been observed in the last stages of cirrhosis (Peters and van Slyke, 1946; Halbertsma, 1932). In this case, however, the absence of ascites, jaundice, and wasting shows that the disease was hardly in the last stage. Moreover, there had been recovery from the previous attack. Peters *et al.* point out that the hypoglycaemia of liver disease characteristically appears at the end of a considerable period after meals, and that often it is preceded by alimentary hyperglycaemia.

My thanks are due to Dr. H. Oakley White for permission to publish this case; to Dr. H. H. Gleave for the post-mortem examination, results of pathological and histological investigations, and comments; and to Dr. G. Ormiston for helpful criticism and advice.

Medical Memoranda

Spontaneous Subarachnoid Haemorrhage in Infancy due to Angioma of the Cerebellum

The rarity of spontaneous subarachnoid haemorrhage in infancy and the nature of the pathology of this case prompt its presentation for publication.

CASE HISTORY

The patient, a male infant, was the only child of healthy parents and had been born at full term by a normal labour. The neonatal course was uneventful, and he progressed well in all respects up to the age of 3½ months. Then suddenly one afternoon, while being dressed by his mother, he had a convulsion and became semicomatose. He remained in this state, punctuated by recurring generalized fits, until his admission to hospital some hours later. There was no history of any antecedent illness, and the family history revealed nothing of note.

On admission his temperature was 104° F. (40° C.). His condition was that of a resistant stupor. The head was held turned towards the right shoulder and there was conjugate deviation of the eyes to the right. A capillary naevus 3 cm. in diameter was noticed over the left occipital region, and a small capillary naevus was present on the right upper eyelid. The fontanelle was not bulging, but it felt spongy. The head circumference was 17 in. (42.5 cm.). The pupils were of normal shape and reacted to light; no abnormality was seen in the fundi. The head deviation made the assessment of any nuchal rigidity difficult, but there was no spasticity or obvious paralysis of any of the limbs. The heart rate was markedly irregular, tachycardia and bradycardia alternating in an inconstant manner. No other abnormality was found. Lumbar puncture produced 6 ml. of evenly blood-stained C.S.F.; the supernatant fluid was yellow.

Thiopentone per rectum and chloral hydrate were given to control the fits, and 500 mg. of ascorbic acid and 10 mg. of "synkavit" were injected intramuscularly every six hours. Oesophageal feeding was used. No significant change in his condition occurred until two days later, when oedema of the eyelids, right-sided facial spasm, and spasticity of all limbs were noted. A lumbar puncture, done four days after the onset of the illness, again showed a blood-stained C.S.F.

The next day saw considerable improvement in the clinical condition. The fits had ceased, the temperature was almost normal, and the patient was able to take feeds from a bottle. By the ninth day the palpebral oedema had subsided, the deviation of head and eyes and spasticity had relaxed, the temperature was normal, and he was taking notice and feeding eagerly.

This satisfactory state continued for three days. Then his temperature suddenly rose to 104° F. (40° C.), subsequently reaching 107° F. (41.7° C.). No abnormal physical signs were found except for a slight reddening of the left ear-drum. Microscopical examination of the urine and an x-ray film of the chest showed no abnormality. Lumbar puncture produced a clear C.S.F. with a high chloride content (860 mg. per 100 ml.).

A left myringotomy was performed, but no pus was obtained. Hyperpyrexia (107° F.; 41.7° C.) persisted until his death in coma two days later.

Post-mortem Examination.—There was some pooling of blood in the subarachnoid space in the posterior fossa, together with blood-pigment staining. A venous plexus was present over the surface of the left cerebellar hemisphere and one of the vessels had ruptured, the aperture being filled with blood clot. In the substance of the left cerebellar hemisphere there was a vascular neoplasm 3 cm. in diameter, with haemorrhage into it and into the surrounding brain tissue. The left choroid plexus was thrombosed. No tumour was found in any other part of the nervous system and no cysts or tumours in any other organ. The middle ears were healthy and no other disease process was found.

Histological Examination (Professor J. Gough).—"The sections of cerebellum show a haemangioblastoma. In parts there are cellular tissues with ill-developed blood spaces; elsewhere there are cavernous spaces. There is surrounding gliosis and evidence of old and recent haemorrhage, resulting in the formation of haemosiderin and haematoidin. Intense macrophage activity is present."

This case is interesting in that the subarachnoid bleeding occurred abruptly in an apparently healthy infant aged 3½ months, and in the association between two capillary-naevi in the head area and a venous plexus over the surface of the left cerebellar hemisphere with a haemangioblastoma in its substance. The sequence of events is thought to have been, first, rupture of one of the veins of the plexus overlying the cerebellum, producing subarachnoid haemorrhage, then an

interval of quiescence leading up to the final and fatal haemorrhage in the substance of the cerebellum containing the haemangioblastoma.

We wish to thank Mr. Melbourne Thomas for permission to publish this case; and we are indebted to Dr. D. C. Taylor and Professor J. Gough for the post-mortem examination and the histological report.

Case of Rupture of Left Lower-Lobe Bronchus with Recovery

Traumatic rupture of the bronchus is a rare condition, and is seldom diagnosed. Many of the cases are fatal, as they are associated with severe crushing injuries of the chest. Kinsella and Johnstrud (1947) reported 38 cases. In the following case the rupture occurred without any fracture of the ribs, though presumably the chest must have been compressed, possibly by the motor-cycle falling on it.

CASE HISTORY

A man aged 24 met with a motor-cycle accident in December, 1946, and sustained concussion, multiple abrasions, and a fracture of the right humerus. He was admitted to the City General Hospital, Sheffield, where he recovered fairly quickly; he was discharged towards the end of January. In February, 1947, he became ill, left lower-lobe pulmonary pneumonia being diagnosed, and was re-admitted to hospital. He recovered on sulphonamide therapy, and was discharged. One year later he again became ill, beginning with a rigor and pain in the lower part of the left side of his chest. This lasted a few days, after which he got up and went about but did not feel very well. He had aches in various parts of his body, felt feverish, and had a fairly severe headache most of the time.

He was sent to the Royal Infirmary, Sheffield, as a case of pneumonia. He once more settled down, and his temperature became normal; an x-ray film, however, revealed a collapse of the left lower lobe. I was asked to see him, and after bronchoscopy and bronchography at the City General Hospital I diagnosed a probable

rupture of the left lower-lobe bronchus. The bronchogram showed failure of the left lower lobe to fill, and the bronchoscopy failed to disclose any evidence of entry to the lower lobe. The upper-lobe bronchus was rotated downwards, and the bronchoscope could be introduced into it quite easily. Lobectomy was advised and was carried out at the City General Hospital.

At operation it was found that the left lower-lobe bronchus had been torn partly across, and had only fibrous tissue on one wall, but there was some cartilage still in continuity with the main left bronchus. There was no passage between the lower lobe and the main bronchus, and it was therefore not necessary to suture the bronchus. The man made an uninterrupted recovery and was discharged a fortnight after operation.

The left lower lobe was completely bronchiectatic and the bronchi were filled with an albumin-like substance, apparently inspissated

mucus. It coagulated with formalin. Pus was not found in any of the bronchi, and the infection seemed to have died down.

The accompanying illustration shows the appearance of the specimen.

I am indebted to my chief assistant, Miss Slessor, for performing the bronchoscopy and for the bronchogram.

A. W. FAWCETT, F.R.C.S.

A Case of Spontaneous Rupture of the Uterus

In view of the comparative rarity of this condition the following case seems worthy of record.

CASE REPORT

A married woman was admitted at term at 2.45 a.m. She had been delivered fifteen months previously, with forceps, of a living child of 8 lb. 4 oz. (3.74 kg.). Post-natal examinations made on two occasions by a member of the consultant staff revealed no injury to the cervix or the vagina. Apart from retention of urine and slight rise of temperature, the puerperium was uneventful.

The present pregnancy had been normal. Labour had begun 12.45 a.m. with a show and contractions which were one in the minutes on admission. On examination the presentation was L.O. with the head in mid-cavity. The membranes ruptured at 3.15 a.m. and the cervix was fully dilated at 3.45 a.m. At 4.50 the head was visible but was progressing very slowly, and the foetal heart became weak and irregular. Five minutes later a particularly strong contraction was felt, after which no further contractions were observed. The patient complained of a dull ache in the abdomen, but her pulse and colour remained normal. On examination the abdomen was slightly tender and a group of limbs were felt very easily; the umbilicus, but the uterus appeared of uniform thickness above and below this point. The foetal heart was inaudible.

The history suggested a ruptured uterus, but in view of the absence of shock or haemorrhage it was decided that the foetus should be delivered. Pitocin was given immediately before. Under anaesthesia the head was found in an anterior position with little caput or moulding and a foetus was delivered without difficulty, although the subpubic angle was rather narrow. It was stillborn and weighed 7 lb. 15 oz. (3.6 kg.). The cord was traced up the vagina in the peritoneal cavity through a tear in the lower segment and cervix. The uterus lay above and was well contracted. There was little haemorrhage and the patient's general condition was satisfactory.

At laparotomy a vertical tear was found in the lower segment extending through the cervix into the anterior vaginal wall about 4½ in. (11.25 cm.). This was repaired in two layers. The patient became very shocked at the end of the operation, and an intravenous transfusion of 2 pints (1.14 litres) of Group O blood was given. After a prophylactic course of sulphadiazine and penicillin uninterrupted recovery followed.

On discharge, on the nineteenth day, the vagina and cervix were healing satisfactorily. Two months after delivery the anterior vaginal wall was almost healed and the cervix completely healed.

COMMENT

This case is one of spontaneous rupture of the uterus in the course of a rapid labour with strong contractions. Rupture occurred when the head was still descending, though more slowly than earlier in the second stage. There was no evidence of disproportion, since the head was well flexed in an occiput anterior position with little caput or moulding, the foetus being also smaller than the first baby. No sign of weakness or injury of the birth canal was found after the first confinement. The lower segment was not unduly thinned at laparotomy. The obvious explanation would appear to be that the magnitude of the contractions caused the tension in the uterus to rise at such a rate that it ruptured before the tension could be released by downward movement and delivery of the head.

The case is also remarkable for the lack of constitutional disturbance associated with a tear 4½ in. long involving the lower segment, cervix, and anterior vaginal wall, there being no clinical evidence of shock till the close of the laparotomy nearly four hours after the time of rupture. The tear was situated almost in the midline, thereby avoiding the large vessels, which may offer at least some partial explanation of these facts.

I wish to thank Mr. A. R. Lister for performing the laparotomy for advice on the conduct of the case, and for criticisms of this report.

G. B. CHAMBERLAIN, M.B., B.S., D.R.C.O.G.,
Resident Medical Officer, York Maternity Hospital.

Reviews

BIOCHEMISTRY REVIEW

Annual Review of Biochemistry. Editor, J. Murray Luck; Associate Editors, Hubert S. Loring and Gordon Mackinnay. Volume XVII. (Pp. 801. \$6.00 or £1 16s.) California: Annual Reviews, Inc. London: H. K. Lewis and Company. 1948.

The *Annual Reviews* began, with the *Annual Review of Biochemistry*, as a luxury, but have now become a necessity, even though more and more specialized volumes are published each year. The literature is growing at such a pace that though reviewers have been asked by the editors to screen the literature more and more severely, and if need be to review but a fraction of the papers published in the preceding year or biennium, recent volumes of the *Annual Review of Biochemistry* have approached or exceeded 800 pages. The decision has therefore been taken to institute a new review, and in 1950 it is proposed to start an *Annual Volume of Plant Physiology*. While such a high degree of specialization is to be regretted from some points of view, those who are working in specialized fields of research realize its inevitability.

The present volume contains reviews on the following subjects: Biological Oxidations and Reductions, by H. Weil-Malherbe. Nonoxidative Enzymes, by J. B. Sumner. Chemistry of the Carbohydrates, by D. A. Prins and R. W. Jeanloz. The Chemistry of the Immunopolysaccharides, by W. N. Haworth and M. Stacey. X-ray Crystallographic Studies of Compounds of Biochemical Interest, by D. Crowfoot. Chemistry of the Lipids, by J. Folch-Pi and W. M. Sperry. The Chemistry of the Proteins and Amino Acids, by K. O. Pedersen. Nucleoproteins, Nucleic Acids, and Related Substances, by E. Chargaff and E. Vischer. Carbohydrate Metabolism, by B. Vennesland. Lipid Metabolism, by I. L. Chaikoff and C. Entenman. The Metabolism of Proteins and Amino Acids, by J. B. Allison. The Metabolism of Drugs and Toxic Substances, by O. Bodansky. Clinical Applications of Biochemistry, by L. J. Zeldis and S. C. Madden. Biochemistry of the Hormones, by T. F. Gallagher. The Vitamins, by B. L. Oser. Clinical Aspects of Vitamins, by T. D. Spies. The Biochemistry of Carcinogenesis, by H. P. Rusch and G. A. LePage. Biochemistry of the Natural Pigments, by E. Lederer. The Terpenes (in relation to the Biology of Genus Pinus), by N. T. Mirov. The Alkaloids, by R. F. Dawson. Photosynthesis, by E. C. Wassink. Mineral Nutrition of Plants, by H. Burström. Plant Hormones, by P. W. Zimmerman and A. E. Hitchcock. Bacterial Metabolism, by I. C. Gunsalus. The Chemistry of Penicillin, by E. Chain. Ruminant Digestion, by S. R. Elsdon and A. T. Phillipson. Physiological Aspects of Genetics, by G. W. Beadle.

Many of these follow the usual lines, although the authors treat their subjects very differently. In the review on clinical applications of biochemistry Zeldis and Madden discuss serum potassium phosphatases, blood iodine, electrophoresis, liver function studies, and porphyrins. The article on the chemistry of penicillin by E. Chain is of exceptional clarity and will interest the chemistry-minded medical man who wishes to have some idea of this rather complicated matter. Perusal of this article will yield ample understanding of the delays there have been in providing a satisfactory synthesis of the naturally occurring penicillins. Among reviews of topical importance that on ruminant digestion by Elsdon and Phillipson brings together much material that has been developed by the late Sir Joseph Barcroft and his group at Cambridge in relation to the earlier and contemporary observations. This is a most interesting field of study which, although it may have little direct application to human digestion, may nevertheless be of growing importance in the "Malhusian" world which we now appear to inhabit. The article on the physiological aspects of genetics by G. W. Beadle is reprinted from Vol. X, 1948, of the *Annual Review of Physiology* and deals with what may be regarded as the experimental descendant, particularly in regard to micro-organisms, of the work on naturally occurring "inborn errors of metabolism" pursued by Garrod and others many years ago.

The biochemist cannot afford to be without the *Annual Reviews of Biochemistry*, and specialists in other fields of

activity find the yearly volume an invaluable reference book. The non-specialist will find much of interest to read within the 800 or so pages of the current volume, and it is to be hoped that he will close the book with the impression that biochemistry is perhaps not such a difficult and complicated subject as is sometimes believed.

F. G. YOUNG.

TUBERCULOSIS DISCUSSED

Tuberculosis. A Discussion of Phthisiogenesis, Immunology, Pathologic Physiology, Diagnosis, and Treatment. By Francis Marion Pottenger, A.M., M.D., LL.D., F.A.C.P. (Pp. 597; illustrated. £3.) London: Henry Kimpton. 1948.

The author of this long and diffuse book presents in discursive style his views on the "phthisiogenesis, immunology, pathologic physiology, diagnosis, and treatment" of tuberculosis, with especial reference to pulmonary tuberculosis. Dr. Pottenger has strong views on many controversial topics and puts them forcefully. He regards primary infection as valuable in creating specific protection, and accordingly he is a keen advocate of B.C.G. vaccination. His approach to therapy is enthusiastic, and his optimism must have been a valuable therapeutic aid for his patients. He is convinced of the continued value of physical examination of the chest in the diagnosis of pulmonary tuberculosis, but emphasizes that for the non-specialist the "clinical history, examination of the sputum for tubercle bacilli, and the x ray" are the important factors. He devotes a chapter to the treatment of pulmonary tuberculosis by tuberculin, though he admits that he considers the evidence for its value in pulmonary tuberculosis not so impressive as in some other forms of the disease, that its value cannot be proved by controls, and that he cannot claim that the beneficial effects he has observed are due to the tuberculin, since he applies "rest, open air, nutritious food, sunlight, pneumothorax, optimism, and other factors" in addition.

These remarks may serve to indicate the very personal views which are expressed in the book. Based as they are on a lifetime of experience and study of tuberculosis, they will ensure that the book can be dipped into with interest by specialists. It may be doubted, however, whether the likelihood of obtaining from it a reliable background of accepted modern views is sufficient to justify the student's perusing its approximately 600,000 words.

D.D.T. FOR MOSQUITOES

Malaria, Filariasis, and Yellow Fever in British Guiana. By George Giglioli, M.D.Sc., M.R.C.P., D.T.M.&H.Eng. (Pp. 226; illustrated. No price.) British Guiana: Mosquito Control Service Medical Department. 1948.

The subtitle of *Malaria, Filariasis and Yellow Fever in British Guiana* is "Control by residual D.D.T. methods with special reference to the progress made in eradicating *A. darlingi* and *Aedes aegypti* from the settled coastlands." The reason why three major diseases are discussed together is that all are conveyed by mosquitoes and therefore all are now open to successful attack through D.D.T. Further, since the possibility of attacking anopheline mosquitoes with a residual insecticide in the home rather than through antilarval measures in the field has become one of the major measures in anti-malaria work, it has increasingly meant that measures against malaria can be combined with those against all insect-borne disease transmitted in the home. The area considered is largely given over to sugar-cane cultivation, and the conditions, as is evident from the photographs accompanying the work, would clearly be impossible to deal with by drainage or the usual type of antilarval operations, since for cultivation purposes the land is largely under water. Hence D.D.T. has been used, causing drastic reduction in the total domestic mosquito population, without any modification in the hydrological conditions, which have remained what they always were.

The operations were carried out by the Mosquito Control Service working in collaboration with staff from the British Guiana Sugar Producers' Association. The materials used, spraying equipment, dosage, and other technique, as also the organization, costs, and results, are all clearly described.

Malaria was the chief disease, being highly endemic, and it therefore received first attention. -But filariasis was also important and the appearance of yellow fever always a possibility, so that operations included action against *C. fatigans* and *Aedes aegypti*. It is interesting to note that the use of D.D.T. is far from being a purely routine matter with no call on the results of research, and the author expressly notes, if success is to be attained, the absolute necessity of close research into the habits of the adult, just as antilarval operations require research into the selective breeding habits of the different species.

S. R. CHRISTOPHERS.

PREFERENCE JUDGMENTS

Experimentelle Triebdiagnostik (Experimental Diagnosis of Impulsive Disorders). By L. Szondi. (Pp. 308. 68 Swiss francs.) Berne: Medizinischer Verlag Hans Huber.

The author of this somewhat formidable work is concerned to introduce a new psychodiagnostic method, obviously inspired by the Rorschach technique. The material consists of six sets of eight full-face photographs of various types of psychopathic individual, and is provided with the volume. Each set is presented in turn to the subject, who is required to indicate which of the individuals portrayed he finds most attractive and which most distasteful. The preference judgments thus obtained are recorded as a profile from which, it is claimed, certain conclusions of psychodiagnostic import can be drawn. The bulk of the volume consists in a description of the profiles made by a variety of psychotic and psychoneurotic individuals and an attempt to interpret them in the light of the author's reading of contemporary psychopathology.

It appears rather unlikely that Dr. Szondi's method will commend itself to clinical psychologists in this country. Although the analysis of preference judgments is a matter of some psychological interest, especially in so far as it may furnish a clue to the operation of deep-seated unconscious tendencies, the existing findings are too slight to justify the elaborate interpretations which Dr. Szondi puts on them. His test photographs, too, are so antiquated and repellent as to deter all but the most hardy and humourless of psychometrists. From the theoretical standpoint, the book appears to contribute little that is new to our understanding of personality, normal or deranged. It is turgid, verbose, and representative of the worst aspects of neo-Freudian psychopathology. One may fervently hope that the "Szondi test" will not become the focus of yet another esoteric cult in the psychological fraternity.

O. L. ZANGWILL.

HORMONES AND BEHAVIOUR

Hormones and Behaviour. A Survey of Interrelationships between Endocrine Secretions and Patterns of Overt Response. By Frank A. Beach. Foreword by Earl T. Engle. (Pp. 368. \$6.50.) New York: Paul B. Hoeber, Inc. London: Hamish Hamilton. 1948.

The author of this painstaking book gathers into one volume an almost staggering amount of information about the effects of the endocrine glands on the behaviour of fishes, amphibia, reptiles, birds, the lower mammals, and the primates, including man. If the last receives less attention than he himself would consider to be his fair share, that is his own fault in failing to control scientifically his experiments on himself and in degrading too often the proper study recommended by Pope into an improper study. Courtship, mating, bisexuality, oviposition, parturition, parental behaviour, migration, aggression, territorial defence, the acquisition of learning, metamorphosis, metabolism, are all fully considered—considered but not discussed, for the weakness of the book lies in its paucity of critical discussion of the results reported.

But if we are inclined to condemn this book as a scissors-and-paste compilation we have at once the author's reply: "Most books, it seems to me, develop in one of two ways . . . the second type . . . has a well-defined function to fulfil. Its role is not the exposition of a thesis, but the supplying of a body of facts and references. It is not a living organism but an inanimate tool and as a tool it may play a useful and important part." Not "may"—"will."

RAYMOND GREENE.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Essen und Wissen. By H. Bircher-Rey. 2nd ed. (Pp. 203. No price.) Zurich: Rascher. 1948.

A book on dietetics intended for laymen as well as medical men.

Histopathology of the Peripheral and Central Nervous Systems. By G. B. Hassin, M.D. 3rd ed. revised. (Pp. 612. \$8.50.) Chicago: The Author. 1948.

A textbook with illustrations and extensive bibliographies.

Subacute Bacterial Endocarditis. By E. Libman, M.D., and C. K. Friedberg, M.D. 2nd ed. (Pp. 113. 21s.) New York and London: Geoffrey Cumberlege. 1948.

A review in the light of recent knowledge; reprinted from the *Oxford Loose-Leaf Medicine*.

Change of Life in Women. By Medica. (Pp. 76. 5s.) London: Delisle, Ltd. 1948.

A simply written account for women by a medical practitioner.

A Surgeon's Domain. By B. M. Bernheim, M.D. (Pp. 217. 9s. 6d.) Kingswood, Surrey: The World's Work (1913), Ltd. 1939. Reminiscences and opinions of the Associate Professor of Surgery at Johns Hopkins Medical School.

Zinc Ions in Ear, Nose, and Throat Work. By A. R. Friel, M.D., F.R.C.S.I. (Pp. 59. 5s. 6d.) Bristol: John Wright. London: Simpkin Marshall. 1948.

An account of zinc electrolysis and ionization.

Children in Need. By M. Schmideberg, M.D. (Pp. 196. 12s. 6d.) London: George Allen and Unwin. 1948.

The author describes psychiatric and social methods of treating difficult children and their parents.

The Structure of Medicine and its Place Among the Sciences. By F. M. R. Walshe, M.D., D.Sc., F.R.C.P., F.R.S. (Pp. 26. 1s. 6d.) Edinburgh: E. and S. Livingstone. 1948.

The 1948 Harveian Oration.

Handbook of Surgery. By E. C. Mokie, M.B., Ch.B., F.R.C.S.Ed., F.I.C.S., and I. Mackenzie, M.B.E., M.B., Ch.B., F.R.C.S.Ed. 2nd ed. (Pp. 764. 20s.) Edinburgh: E. and S. Livingstone. 1949.

Intended particularly for medical students; the text has been extensively revised for this edition.

The Scotsman's Food. By A. H. Kitchin, M.B., and R. Passmore, M.A., D.M., F.R.S.Ed. (Pp. 86. 3s. 6d.) Edinburgh: E. and S. Livingstone. 1949.

A historical introduction to modern food administration.

Psychological Medicine. By D. Curran, M.B., F.R.C.P., D.P.M.; and the late E. Guttman, M.D., M.R.C.P. 3rd ed. (Pp. 249. 12s. 6d.) Edinburgh: E. and S. Livingstone. 1949.

A practical guide for the non-specialist.

Introductory Botany. By A. Nelson, B.Sc., Ph.D., D.Sc. (Pp. 479. 22s. 6d.) Edinburgh: E. and S. Livingstone. 1949.

A textbook for medical students.

The Story of Human Birth. By A. F. Guttmacher, M.D. (Pp. 201. 7s. 6d.) London: Sigma Books. 1949.

An account for the layman.

Bacterial Metabolism. By M. Stephenson, Sc.D., F.R.S. 3rd ed. (Pp. 398. 30s.) London: Longmans, Green and Co. 1949.

A description of the essential chemical processes accompanying the life of bacteria. (Dr. Stephenson died in December, 1948.)

Neurological Anatomy in Relation to Clinical Medicine. By A. Brodal. (Pp. 496. 42s.) Oxford: Geoffrey Cumberlege. 1948.

A textbook for clinical neurologists by the Professor of Anatomy, Oslo University.

A Handbook for the Assistant Nurse. By M. E. Swire, S.R.N., S.C.M. (Pp. 308. 10s. 6d.) London: Baillière, Tindall and Cox. 1949.

A textbook intended to cover the syllabus for assistant nurses.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MARCH 19 1949

THE KING'S HEALTH

Over the last four months occasional bulletins from his medical advisers have kept the public informed of the state of the King's health. The medical profession in Britain shared to the full the anxiety felt by all his subjects when the first bulletin was issued in November and the relief that followed the better news contained in later bulletins. The medical profession has been aware of the kind of problem that would be presented to the King's advisers, and the bulletin issued on March 8 did not, therefore, come as a surprise. This bulletin stated that the King's general health continued to be excellent. It went on to describe how the circulation had been satisfactorily restored in the left leg but was still obstructed in the right leg. The King accepted the advice that lumbar sympathectomy should be undertaken with a view to improving the blood supply to the right foot, and the operation was performed on March 12.

The medical profession will join with the rest of the country in heartfelt sympathy for the King and a loyal wish that the operation will bring his Majesty relief and comfort.

SYMPATHECTOMY IN PERIPHERAL VASCULAR DISEASE

Knowledge of the sympathetic nervous system has been acquired slowly. Galen described the sympathetic chains arising within the skull, but the first correct anatomical description was published by Petit only in 1727. There were gradual additions to anatomical knowledge over the next two centuries, but there was no true understanding of the functions of the autonomic nervous system until the brilliant researches of Gaskell and Langley. The first surgical attack on the sympathetic system accompanied the publication of these physiological investigations, but the early operations were ill-conceived. The earliest operations were performed in cases of epilepsy in 1889 by Alexander.¹ Ten years later Jaboulay treated patients with toxic goitre by cervical sympathectomy, but his results, like Alexander's, were poor, and interest in this branch of surgery waned. The modern application of sympathetic surgery to the treatment of peripheral vascular disease may be said to have started with the periarterial sympathectomies of Leriche,² but the results were evanescent and uncertain. The trial of ramisection and ganglionectomy in the treatment of peripheral vasospastic disorders followed the discoveries made accidentally by Hunter³ and Royle,⁴ who were treating cases of paralysis. Since then a great deal of work has been done on this subject, but even now we remain in ignorance of many

apparently simple and straightforward matters. Sympathectomy is now widely employed in the treatment of peripheral vascular disease, and it may be useful to review the present position.

Sympathectomy remains the most satisfactory method of treatment in Raynaud's disease proper, although it is indicated only in a minority of cases. Before advising operation the diagnosis must be established with certainty, and the degree of disability and the severity of the disease in the individual case must be carefully considered. Operative treatment is especially indicated when increasingly severe attacks are occurring with each fresh spell of cold weather; in moderately advanced cases without ulceration or scleroderma; and in late cases with painful superficial ulcers. Recurrence is more likely in the latter cases, and they may then develop scleroderma, which, in the absence of sweating following sympathectomy, may sorely handicap the patient. In the upper extremity sympathectomy gives complete and permanent relief in rather more than 10% of cases; incomplete relief in some 50%; and no relief or but transient relief in the remainder. The results obtained seem to depend on the completeness of the operation and the stage of the disease. Failure has been ascribed to incomplete operation, anatomical variations, regeneration of nerve fibres, and the sensitization to adrenaline. There has been a disinclination to accept the possibility of nerve regeneration, although it has been shown that this is the most likely factor.^{5,6} The new pathways so formed are probably functionally inferior to the original ones.⁷ The much more satisfactory results obtained in arterial disease in the lower limbs, the operation being preganglionic, led to the abandonment of the old anterior cervico-thoracic sympathectomy for arterial disease in the upper limbs. This operation was supplanted by what was believed to be an essentially preganglionic operation performed through a posterior approach, and early reports suggested that this procedure was an improvement on the former operation. However, more recent work has revealed a considerable gap in our detailed knowledge of the exact ganglia in which the relay occurs of those sympathetic fibres destined for the arm. The expected advantages of the new operation have not been entirely realized, and doubt has arisen about whether these various operations are pre- or post-ganglionic. Furthermore it would seem that it is possible to perform an equally effective though slightly less extensive operation through the more simple anterior approach.

Apart from Raynaud's disease sympathectomy is also of value in the treatment of certain other vasospastic conditions. In the few cases of acrocyanosis which warrant sympathectomy the results are usually better than in Raynaud's disease. The cold and paralysed limb which may result from anterior poliomyelitis is greatly benefited by sympathectomy. In cases of post-traumatic (Sudeck's) osteoporosis associated with a Raynaud-like phenomenon

the operation is absolutely contraindicated. There is also little evidence to support its application to the treatment of chronic ulcers of the leg or of venous insufficiency following thrombophlebitis.

The value of sympathectomy in the treatment of organic arterial disease depends on a number of factors. The majority of arteriosclerotic subjects are old, their expectation of life is limited, and the risks of operation are greater. Even so lumbar ganglionectomy may be of distinct value in some of these cases. The operation is best reserved for patients under 60 and for cases showing good response to vasomotor tests; and there should be no ulceration or gangrene and an apparently sound myocardium. Lumbar ganglionectomy relieves rest pain, alleviates claudication in some cases, and it improves the blood supply to the muscles and to the toes. The abolition of sweating is also of value in preventing excessive cooling of the limb. Although as a general rule the operation will prove of less value in a patient with an absent popliteal pulse it is impossible to be dogmatic about this, and successes have been recorded in some of the most unpromising cases, the prognosis being better in those cases of popliteal block with a warm foot. It would seem likely that the legs are better able to stand up to minor trauma and the insult of further arterial occlusion after sympathectomy, and the surgeon should not be too readily influenced by the clinical state of the pulses, basing his assessment rather on the results of vasomotor tests.

Lumbar ganglionectomy is of value in many cases of thromboangiitis obliterans, although it would not seem to have any significant effect upon the general course of the disease. The risks of operation are slight in the younger age groups affected by this disease, and it is worth doing almost anything which will improve the circulation. The operation is contraindicated, however, in cases with severe arterial insufficiency and gangrene of the digits. The best results are seen in those cases with mild rest pain, minimal ulceration, and a slowly progressive disease. In both arteriosclerosis and thromboangiitis obliterans it is clear that success is dependent on the number of arteries capable of undergoing dilatation and unaffected by gross disease. Total blockage of the popliteal artery will not prevent the recovery of reasonable function so long as there is a good collateral circulation and the progression of the arterial changes is slow. The prognosis will also be influenced by the ability of the patient to live within the limits imposed by his disease. In thromboangiitis obliterans Boyd⁸ differentiated between proximal and distal types of disease and suggested that the prognosis is better in the latter cases. This has been confirmed in the follow-up of a recent series published by Kinmonth⁹; it should be stressed, however, that such subdivision of cases may sometimes be fallacious, because a number of the so-called "proximal" cases may also have some undetected damage to the distal vessels.

Finally, it is necessary to consider the application of sympathectomy to the treatment of acute arterial conditions. In wounds of the peripheral arteries it was suggested that a suitable sympathectomy performed at the time of the primary operation might open up the collateral circulation and obviate reflex vasospasm. This is an appealing argument which has been strongly supported by

Boyd,¹⁰ but it has not found general favour; and it would seem easier to treat such cases by paravertebral sympathetic block should sympathetic interruption be considered desirable. Similar arguments apply in the case of ligation of the major arteries, where the procedure is of possible value, and also in arterial embolism, although in these cases the condition of the patient would usually suggest paravertebral block in preference to sympathectomy.

REMUNERATION OF SPECIALISTS

The Ministry of Health has at last issued its proposed terms and conditions of service for consultants and specialists in the National Health Service. The proposals have been drawn up after preliminary discussions with the Joint Committee of Consultants and Specialists, but do not represent final agreement. They are published in this week's *Supplement* for the information of the profession, and after the various professional bodies have examined the proposals the Joint Committee will put its considered views before the Ministry.

The report of the Spens Committee on the remuneration of consultants and specialists was published nearly a year ago, and since July, 1948, consultants and specialists have been anxiously awaiting the Ministry's interpretation of this. The task of the Spens Committee was to determine the range of total professional remuneration which should be applied to consultants and specialists in any publicly organized hospital and specialist service. The Committee, in determining this, had to take into account financial expectations in the past, and also "the desirability of maintaining the proper social and economic status of specialist practice and its power to attract a suitable type of recruit, having regard to other forms of medical practice." The recommendations of the Spens Committee were made in terms of the 1939 value of money, and the Report emphasizes as strongly as possible that adjustments necessary "should have direct regard not only to estimates of the change in the value of money but to the increases which have in fact taken place since 1939 in incomes both in the medical and in other professions." In this connexion we may note the Chorley Committee's proposals for remunerating higher Civil Servants, which have been accepted by the Government. The salaries of permanent secretaries and deputy secretaries in Government Departments have been increased by 50% above the salaries of these officers in 1939. It is not unfair to assume from this that the Government regards 50% as a reasonable betterment factor.

For staff specialists the Spens Report recommended that incomes should range from £1,500 to £5,000 a year. The upper limit of this range was to be secured for 4% of consultants and specialists by the addition of a special award of £2,500. Staff specialists appointed at the age of 32 were to receive a starting salary (that is, for a whole-time appointment) of £1,500 a year, rising by annual increments over eight years until at the age of 40 a salary of £2,500 a year would be reached. After the age of 40 consultants and specialists would be eligible for the special awards. In addition to the award for the 4% there were to be awards of £1,500 for 10% and £500 for 20% of consultants and

specialists. If we compare with the Spens recommendations the Ministry's present proposals, which are to be referred to the various bodies and committees which represent consultants and specialists, we see that the basic salary range for consultants and specialists is now £1,700 at the age of 32, rising to £2,750 a year at the age of 40. The latter figure in this basic salary range is the maximum accepted by Sir Stafford Cripps for full-time clinical professors.¹ The increase over the Spens figure is 13% at the start and 10% at the finish. If allowance is made for the 8% which is the contribution of the Government to superannuation it is seen that a betterment factor of 22% is applied to the starting salary, and of 19% to the salary reached at the age of 40. The special awards remain as they are. On the Ministry's present proposals 4% of all consultants and specialists, on the assumption of whole-time employment, would receive an annual income of £5,250. It is as well to recall that these awards are open also to those who serve part-time in the consultant and specialist service, adjusted in proportion to the income they earn as part-time workers. Whole-time clinical professors, lecturers, and readers are to be paid the salaries recommended by the University Grants Committee to the Chancellor of the Exchequer; in addition they will get appropriate expenses for hospital work and also be eligible for the distinction awards. Those who hold part-time clinical teaching posts will receive remuneration in recognition of their teaching duties. As the cost of living for the middle and professional classes has risen by 85% since 1939 consultants and specialists are as unlikely as general practitioners to be content with a betterment factor which is 22% or lower at different points in the range of incomes recommended. Consultants and general practitioners have made joint representation on the betterment factor, and the B.M.A. has put to the Ministry of Health a request for a factor of 70% to be applied to the gross remuneration of general practitioners. Pending the results of the negotiations on this the medical profession will not fail to keep in mind the increase of the salaries of senior Civil Servants by 50% over what they received in 1939.

Although the Spens Committee was appointed to consider the remuneration of consultants and specialists it felt that it could not ignore that of potential specialists. Grouping these into three grades of medical practitioners whose training extended approximately from one to seven years after qualification, the Spens Report recommended a range of income for trainee specialists of from £600 to £1,200 a year in 1939 values of money. The Ministry of Health's proposed range is from £670 to £1,300 a year. Within this range the betterment factor varies between 20% and 17%. It is true that these proposals cannot be exactly compared with those, for example, of the Chorley Committee. But on the basis of this, and also on that of the Ministry's betterment factor of 34% for the general practitioners' gross remuneration in 1946 when the cost of living was up by 45%, now that the cost of living is increased by 85% for professional classes the case for a betterment factor of between 50% to 60% is indisputable on the Government's own reasoning.

The Ministry of Health has put forward new proposals for the remuneration of junior house officers, ranging from

£350 to £450 a year for non-residential posts. For junior hospital medical officers who have held house appointments but are not trainee specialists a salary range of £700 to £1,000 a year (non-residential) is recommended; while for senior hospital medical officers undertaking clinical duties but "not of staff specialist status" the non-residential rate of payment is from £1,300 to £1,750 a year. Medical and deputy medical superintendents in general will be paid for clinical work according to their grading as specialists or senior hospital medical officers, and the Ministry's objective is to reduce to a minimum the time spent by medical staff on administrative duties.

The Ministry of Health document contains a number of detailed proposals for those working part-time in the Service and for domiciliary visits. On the basis of 11 half-days the method of assessing the remuneration is the same as that recommended in the Spens Report. In estimation of the number of half-days the time spent on travelling as consultant adviser to the Board and on visits to cottage hospitals will be included, but not, it may be noted, the time occupied in attending committees—already a heavy burden on those connected with hospitals. Some light relief is provided by the statement that part-time consultants and specialists will not be required to "clock in." Specialists who have no contract with the hospital board but may be called in because of their "unusual experience or interest" will be paid at the rate of 5 guineas a visit—"including any operative work, etc." No doubt those representing consultants will be at pains to define "any operative work" and also the all-embracing "etc." It would be rash to assume that a specialist with "unusual experience" would be eager to undertake "any operative work," not to mention "etc.," for a fee of 5 guineas. The fee for a consultant on a domiciliary visit is 4 guineas, with an additional 2 guineas for such procedures as the use of a portable x-ray apparatus, and 4 guineas for an obstetric operation. The maximum remuneration to be allowed for domiciliary visits is 200 guineas in any quarter or 800 guineas in any year. It is possible that this restriction is intended to prevent the possible abuse of the Service by patients who would demand a specialist's opinion on the slightest provocation; nevertheless, in some areas such a restriction might be to the detriment of the community.

There is space here to touch only on a few of the many other points in the Ministry of Health's proposals. It may be noted that in his contract of service a specialist will be given no fixed period of tenure. There are detailed regulations on such matters as holidays and sick leave; for example, no allowance will be paid to anyone who suffers an accident from "active participation in sport as a profession." This encouragement to the amateur in sport is to be welcomed; but apparently if the amateur who is injured can be accused of "contributory negligence" he will not receive financial sympathy. What group of arbiters is to decide that a man who breaks a bone playing rugby has done this through negligence? If a specialist in the Service is off duty because of ill-health he may be required to be examined by a doctor nominated by the

¹ *British Medical Journal*, 1949, 1, 403.

employing authority. Apparently free choice of doctor is to be denied to a specialist in these circumstances—a curious paradox. Again, an employing authority may take action on receipt of a report that the sick specialist "has been guilty of conduct prejudicial to his recovery." These kinds of proposals seem, in effect, to treat specialists and consultants as if they were irresponsible school-boys, and are informed with that lack of imagination which kindly critics see as one of the attributes of a Civil Servant. When it comes to expenses, for example, we note excessive caution in the requirement that a specialist will be able to recover car-parking fees only on production of a voucher. The mileage allowance is not likely to be accepted without considerable protest.

It is unfortunate that there has been such delay in the issue of the Ministry of Health's proposals. They will have to be closely scrutinized by the various bodies concerned; the views of these bodies will have to be collated and classified by the Joint Committee, whose task it will then be to thrash the matter out on behalf of consultants and specialists with the Ministry of Health. Just how long this will take it is not possible to say, but before everything has been settled consultants and specialists will have spent nearly a year in the Service without knowing exactly what their terms and conditions of service are to be. Apart from the many questions of detail which will have to be looked into closely the one matter of overriding importance is the size of the betterment factor. Government, Parliament, and people have demanded the National Health Service, and, having succeeded in obtaining it, they cannot escape their obligation to pay adequately the men and women who with some reluctance have agreed to work in it.

PARALYTIC POLIOMYELITIS

During the epidemic of poliomyelitis which occurred in this country in 1947 an effort was made to reassure the public by pointing out that few patients developed severe paralysis. McAlpine and his colleagues¹ found that only 26 out of 60 proved cases had paralysis of any kind; of these not more than one-third could be regarded as sufficiently severe for the residual paralysis to affect the patients' future. Although these figures have been widely quoted the fear of the disease is still out of proportion to its social significance. A large epidemic having now occurred, it

comes probable that as in the U.S.A. and Australia there will be recurring epidemics of poliomyelitis in this country, and the effect of reassuring statements is likely to decrease still further. So far no prophylaxis for this disease is available, and the principal measures that can be taken to prevent its spread are early diagnosis and subsequent isolation of all cases. A watch over all contacts for the development of any symptoms is an obvious corollary, but this may be impossible with the present number of doctors. For isolation to be really effective diagnosis must be made in the prodromal or pre-paralytic stage.

In a paper appearing elsewhere in this issue Dr. Ritchie Russell surveys the natural history of paralytic poliomyelitis and analyses the findings in 100 patients. These were all old enough to be questioned in detail—only eight being under 11 years of age. In this way he was able accurately to assess the day-to-day development. Like previous observers Dr. Ritchie Russell describes three stages of the disease—the prodromal, the pre-paralytic, and the paralytic. He found symptoms of the prodromal stage in fewer than half the cases, whereas McAlpine found such symptoms in about 70% of his patients. In any event the signs of a "cold," such as nasal catarrh, sore throat, mild pyrexia, and malaise, are so unspecific that it is questionable whether the diagnosis can be more than guessed at at this time. During an epidemic it is much easier to suspect the condition, but at such a time the diagnosis is made too frequently. Kelleher² found that in only half of 170 cases admitted as poliomyelitis could the diagnosis be confirmed, and McAlpine reported 44 cases out of 104 admissions. This erring on the safe side is to be encouraged so long as hospital beds are available.

The pre-paralytic stage must be regarded as the acute and critical period of the illness. Dr. W. Ritchie Russell argues that at this time the virus is multiplying in the central nervous system and the fate of spinal cells is being decided. The characteristic spinal and limb pains, fever, and malaise now develop. Unfortunately the symptoms and signs may be very slight, and the more robust the patient the easier it is for minor manifestations to be disregarded. Clinicians have already drawn attention to two points: (1) that pains are often greatest in the region which will be most severely paralysed; and (2) that great physical activity in the pre-paralytic stage of the illness is associated with severe paralysis. Dr. Ritchie Russell is now able to confirm these clinical impressions by statistical analysis. He goes even further and produces case records which clearly suggest that physical activity might bring on the acute pre-paralytic phase in a patient who would otherwise have an abortive attack with no more than prodromal symptoms or perhaps no noticeable symptoms at all. In the pre-paralytic stage activity will increase not only the severity but also the extent of the paralysis. It is clear, therefore, that the patients most likely to be affected are those who struggle on courageously but mistakenly during that early phase of their illness. These, as Dr. Ritchie Russell points out, are frequently those with the greatest powers of physical and mental endurance or, like the mother of young children, those who are most anxious not to be ill.

From this account it follows that the physiological state of the neurone is a most important factor in deciding its resistance to the virus. The histo-pathological studies of Scheinker³ suggest how this may occur. He studied the whole nervous system in six cases of poliomyelitis and found a widespread inflammation of the tissues associated with localized parenchymatous destruction of motor elements. The latter is the well-recognized and frequently described lesion of the disease. He then showed that these two responses are independent—the former being a response to invasion, the latter demonstrating the specific lethal effect of the virus on neurones. Once the nervous system is invaded it is questionable whether anything can

¹ *British Medical Journal* 1947 2, 1019.

² *Proc. R. Soc. Med.*, 1947, 40, 931.

³ *Arch. Neurol. Psychiat.*, Chicago, 1947, 57, 565.

be done to modify the general response: this must depend on the strain of the infecting virus, the size of the infecting dose, and the presence of any immunity acquired in previous subclinical infections. The phase of cell damage, however, can perhaps be modified by altering the physiological state in and around the neurone. Fatigue, cold, and trauma in the tissues supplied by the motor cells appear to be the most important circumstances which can be controlled; their presence appears to increase the paralysis and influences perhaps how far it spreads. It is therefore essential that complete rest should be enforced throughout the disease, and particularly in the early stages. Any attempt to "work off" the symptoms is condemned, and all school doctors, matrons, and camp medical officers must be made aware of this. Further, unnecessary trauma, such as injections and inoculations that are not vital, should be avoided.

When an epidemic occurs it is probable that hospital beds for acute cases can always be mobilized in sufficient numbers. Some patients are bound to develop severe paralysis even when the greatest care is taken, and difficulty arises when the time comes for them to be moved from the hospitals to which they were admitted. The regional hospital boards, when making their plans for the rehabilitation of patients suffering from prolonged illness, should make early and adequate provision for these patients. They require careful handling at all stages of convalescence and later industrial retraining under medical supervision.

PSYCHIATRIC INDICATIONS FOR ABORTION

Changes in the law relating to abortion were introduced in the new Swiss penal code which came into force in 1942. Article 120 permits abortion only in those cases where danger to the mother's life or great danger of suffering and lasting impairment of her health cannot otherwise be avoided. Thus the admissible psychiatric indications for abortion come within a compass closely corresponding to what holds in Britain. Abortion on eugenic, racial, or criminal grounds is expressly forbidden in the Swiss code, and Professor Glaus, of Zurich, who has recently reviewed the implications of the new law, thinks that many physicians will regret that the admissibility of an abortion is entirely unaffected by whether or not a healthy child is to be expected or whether or not the pregnancy is the result of rape or incest. In this country the practice is to take a slightly wider view than that now permitted by Swiss law: though there is no acceptable eugenic indication for abortion, yet if a pregnancy were the result of rape the fact could be cited in support of a view, reached on other grounds, that the mother's mental health would probably be damaged by allowing the pregnancy to continue.

Social grounds for abortion have never been admitted in this country, but before the introduction of the new penal code for the whole of Switzerland it was permissible in the Canton of Zurich to take such grounds into account. Glaus suggests that now these indications are excluded social agencies ought to be able to help the mother to such an extent that abortion should not have to be considered, and he believes that Switzerland has not far to go to reach such an ideal state. This would also seem to be true of this country now that family allowances, maternity benefit, and a comprehensive health service are all available.

Nevertheless the over-prolific family will continue to suffer hardship, and for this the Swiss provide the remedy of sterilization; this operation is as yet carried out only in very exceptional cases in Britain, nearly always for a purely medical indication.

In his discussion of admissible psychiatric grounds for abortion Glaus makes a number of comments which are of interest to doctors in this country. Danger to life will arise almost only through the risk of suicide, and this danger will be better overcome as a rule by admission to hospital than by interruption of pregnancy. In Britain admission to hospital is not always so easily arranged, and some patients who have suicidal tendencies but yet are hardly certifiable because of a lack of other evidence of mental disorder may not accept voluntary treatment. In such cases it is often difficult to decide whether abortion is justifiable. Danger to health of the most definite kind arises most commonly in psychotic patients. Nevertheless Glaus believes that adequate grounds for abortion will be very rare in manic-depressive patients, and will be present in schizophrenics only when a previous pregnancy has released a psychotic episode or where an existing schizophrenia is, under direct observation, being worsened by the pregnancy. In epilepsy the question of abortion will be decided by whether or not the fits become more frequent or severe during the pregnancy. Affective psychoses released by pregnancy in mentally retarded and defective patients not infrequently have a very doubtful prognosis and are an adequate indication for abortion. In neurotic reactions arising from the conflict situation Glaus believes that abortion should be considered only in exceptionally serious cases, where social measures are likely to be ineffective and where the personality is of a kind particularly sensitive to psychological stresses and with small power of resistance or adaptation. Few patients would fall into this class. Emotionally distressed women who are refused abortion may later recover completely.

The Swiss law states in definite terms that there must be great danger of severe and lasting impairment of health. In Britain we have not the guidance of a precisely formulated law, clinical practice being governed to a considerable extent by precedent and by public opinion on what is ethical. At present most psychiatrists would admit as adequate reason for abortion a serious risk of damage to maternal health, even if that impairment of health would not be irremediable. This implies a considerably greater latitude than is given in Switzerland, where some may consider the law already allows sufficient scope. It may be that a somewhat wider use of sterilization in women who are unfitted to bear and to rear children would reduce the number of occasions when difficult decisions have to be taken about the therapeutic termination of pregnancy.

AUSTRALIA'S DECLINING BIRTH RATE

The recent emigration of a large number of Britons to Australia reminds us that with a population of little over seven million in a territory of three million square miles Australia has good reason to be troubled by a fall in the birth rate. A few years ago, when the decline became manifest, the Federal Government sought the help of the National Health and Medical Research Council at Canberra. The Council then began an inquiry into the incidence of primary sterility in both males and females; the extent of the practice of contraception; the causes of miscarriages, stillbirths, and neonatal deaths; the influence of medical, surgical, gynaecological, or obstetric conditions on the birth

¹ The National Health and Medical Research Council. *Report of the Committee of Inquiry into the Medical Aspects of the Decline of the Birth Rate*. Special Report Series No. 4. Canberra. 1948.

rate; and the part played by nutrition in successful child-bearing. The facilities available for the investigation of primary sterility were found inadequate to provide a basis for any statement on the subject, although, since the first inquiries were made in 1944, a number of clinics have started work. Details of the inquiry into contraception have already been published. Of the sample of women studied, over 60% admitted the use of contraceptives, and it was found that this did reduce the pregnancy rate compared with the rate for women who did not use contraceptives.

Another report¹ has now been issued which discusses the effect of nutrition upon the course and results of pregnancy and the causes of stillbirth and neonatal mortality. Of the pregnancies investigated 18.6% terminated either in stillbirth or miscarriage. The expert committee took the pre-natal clinics of the Women's Hospitals at Sydney and Melbourne as offering material for inquiry into the nutrition of the expectant mothers and into the influence of medical conditions on pregnancy and parturition. While a relatively large number of women attending the clinics showed initially a marked degree of anaemia, this did not seem to bear any relation to their diet. Nutrition played an important part in the development of the toxæmias of pregnancy, the incidence being much higher among those whose diet during pregnancy was unbalanced. It was also shown that a well-balanced diet predisposed to more efficient lactation. But the investigators reached the conclusion that the level of pre-natal nutrition in Australia is not an important factor in predisposing towards the occurrence of stillbirth, neonatal death, or foetal abnormality. No correlation could be found between the diet during pregnancy and the maternal gain in weight, trend of haemoglobin levels, intercurrent diseases, complications during labour, infections during the puerperium, or the birth weight or growth curve of the infants. This result, of course, is at variance with the findings in other countries, and the reason given is that in Australia the proportion of "poor diets" is much smaller than that obtaining in surveys published elsewhere. The patients on whom the study was made were ordinary hospital patients, but they must have come from socio-economic groups much above those of the women concerned in similar records in recent years in Toronto or in Aberdeen.

Prematurity is given as the most important single cause of neonatal deaths and to a lesser degree of stillbirths. It is urged that measures be taken to investigate the causes of prematurity for which at present there is no apparent explanation. Attention is drawn also to the inadequacy of the prevailing definitions of the premature baby. Other recommendations call for increased facilities for prenatal care, the investigation of haemoglobin levels of pregnant women, and indeed of all women capable of childbearing, the registration of all stillbirths, and a post-mortem study in every case of infant death. The setting up of special hospitals for the care of premature infants in each capital and in the large country centres is also advocated.

Australia is in advance of Great Britain and of Canada in her figures for infant mortality. The Australian figure for 1945 was 31.3 per thousand births; the figure for England and Wales for the same year was 46. But Australia was beaten by New Zealand in this respect, and therefore feels that in some way it is still lagging behind in the application of improved methods of care. It is asked whether it is possible that, in the zeal for improving maternal mortality, the welfare of the offspring has been overlooked. But in maternal mortality Australia has not reached the level of this country. The maternal death rate in England and Wales in 1945 was 1.80 per thousand births and in Australia it was 2.13. The neonatal mortality seems

to be the most obstinate factor in both countries, though in England and Wales during the last five years it has declined from 25.2 per thousand to 22.7, and in Australia, too, there has been a steady improvement during the same quinquennium.

CARDIAC PAIN IN WOMEN

Effort angina and coronary thrombosis are less common in women than in men, though with the passage of time the preponderance of men appears to be decreasing. Thus Mackenzie¹ in 1923 found a ratio of 7 men to 1 woman with angina of effort, and in 1928 Parkinson and Bedford² found only 7 women in 100 cases of coronary thrombosis. But in 1943 figures supplied by the Toronto Health Department³ indicated a 2 to 1 ratio of men to women. Changes in sex incidence, as with changes in the frequency of coronary thrombosis as a whole, are difficult to establish, but it does seem clear that cardiac pain of all kinds is much more frequent in men, though the difference becomes less as age advances. It is also well established that effort angina is a particularly rare occurrence in women unless associated with hypertension. These views are confirmed by Summers,⁴ who found only three patients under 40 years of age in a series of 87 cases of angina of effort occurring in women, 84% of whom had hypertension. The three patients under 40 had diseases other than coronary sclerosis which could account for the pain—two had anaemia and one aortic incompetence. If a woman with a normal blood pressure has chest pain suggesting angina of effort, such a diagnosis must be made with reserve and a search made for some structural change other than coronary disease. Angina depending on anaemia—and there is no doubt this may be the sole cause of the symptom—while rare, is of particular importance, since cure of the anaemia may completely relieve the pain. The reason why men are affected so much oftener than women has never been explained. Summers was unable to find any connexion between smoking and alcohol and angina in his female patients, or with occupation, but McCormick thought that the increase in tobacco consumption by women might be responsible for the apparent recent change in the sex incidence.

THE DAWSON WILLIAMS MEMORIAL

The Dawson Williams Memorial Fund was established by voluntary subscription in 1928 to commemorate Sir Dawson Williams, who was Editor of the *British Medical Journal* from 1898 to 1928. The object of the Fund is to award a prize every two years or at longer intervals in recognition of work done in paediatrics. The last award was made in 1938 to Professor (now Sir) Leonard Parsons for his researches into diseases in children. No award was made during the war years, and the trustees of the Fund have now made two awards for 1948—to Professor Alan Moncrieff for his work for child health, and to Professor J. C. Spence for his researches in diseases of children—a prize of 60 guineas being given to each recipient. The Fund is administered by the following trustees: The Presidents of the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association, the Royal Society of Medicine, and the Section for Disease in Children of the Royal Society of Medicine, and the Editor of the *British Medical Journal*.

THE ECONOMICAL USE OF THE HOSPITAL BED AND OF THE NURSE*

BY

E. B. BROOKE, M.B., M.R.C.P., D.P.H.

Medical Superintendent, St. Helier Hospital

AND

J. P. WETENHALL

Secretary, British Hospitals Association

Much of the content of this memorandum is not new matter. We have, however, deliberately attempted to incorporate a brief reference to the more important aspects which bear directly on the problem of the shortage of nurses. We have done this because we are strongly of the opinion that this problem is not resolvable by piecemeal approach, and that its solution depends upon a simultaneous attack on all its various angles as revealed in a survey which must of necessity be wide.

Although the qualitative and quantitative needs of the nursing profession have already received consideration [see the memorandum on 'Recruitment and Training of Nurses,' submitted to the Ministry of Health jointly by the B.M.A., the B.H.A., and the Medical Superintendents' Society (Part II, Paras. 5-10)—and Addendum by the B.H.A.] it is in connexion with the quantitative aspect that the wider survey is essential.

First the unwelcome fact must be realized that the supply of nurses, actual and potential, if used as hitherto, is and will remain inadequate on account of the woman-power position, as is starkly evidenced by official statistics. In consequence it becomes imperative to view the problem of nurse-shortage not only from the aspects of recruitment and training but also from other closely related aspects, in particular the economical use of the nurse and of the hospital bed. It is convenient first to consider the latter factor.

A. Economical Use of the Hospital Bed

The Nature and Purpose of a Hospital.—There may have been an undue tendency to regard a hospital as primarily a place which provides beds for the reception of the sick—with the specialist and ancillary services as an aid to diagnosis and treatment *after* admission—and so to measure the scope and importance of the individual hospital in terms of beds. The consultative and therapeutic facilities in out-patient departments—which, with a few notable exceptions, have been confined to the erstwhile voluntary hospitals—have not been sufficiently developed as one of several means of affording some relief on bed pressure and also as a means of extending the scope of the work of a particular hospital. We stress the importance of relieving bed pressure not only because a vast growth in the number of available hospital beds is unlikely within the next decade but also because the mere addition of beds itself aggravates the problem of the shortage of nurses without necessarily securing the more efficient provision of hospital treatment. This part of our survey is therefore concerned with any measures which, without undue inconvenience to the patient, can be employed to secure a more economical use of hospital beds at present available.

Out-Patient Departments.—While avoiding extremes, it is possible to regard a hospital more as a polyclinic with beds than as a ward-nucleus with ancillary departments. This approach paves the way to greater discrimination in the selection of patients for admission to wards for acute cases, as contrasted with admissions to a hospital bed of some kind or other. A general extension of consultative and therapeutic out-patient facilities to the hospitals that do not at present possess them is therefore a first step towards avoidance of the admission of patients to a hospital bed in default of other facilities for treatment. The out-patient department also provides the services for determining what type of accommodation

is appropriate where admission is necessary, and is therefore a twofold factor in promoting the economical use of the existing beddage. Even if health centres were ultimately developed along lines which included much of the consultative specialist service at present available only in hospital out-patient departments, the latter would still be necessary, partly as a screen to determine the nature of the accommodation appropriate to the individual patient and partly to provide out-patient treatment in relief of beds.

Short-stay Hostels, Recovery Annexes, or Convalescent Hospitals, and Provision of Various Kinds for the Chronic Sick and for the Elderly and Infirm.—In respect of these three items as aids to the economical usage of "acute" hospital beds, to avoid repetition we would only refer with general agreement to the B.M.A. memoranda "The Care of the Elderly and Infirm" and "The Right Patient in the Right Bed." In particular, we think that in a variety of cases much more use could be made of the patient's own home if appropriate procedures for care, visiting, and supervision were thought out and applied. The services of the voluntary worker could be especially useful in this field. For instance, in the neighbourhood of the St. Helier group of hospitals a "meals on wheels" service for chronic invalids in their own homes has been started by the W.V.S. This domiciliary scheme, with the backing of district nurses and home helps, is reproducing in the home many of the facilities normally available only to hospital in-patients. It is hoped soon to include a laundry service, and already, with the aid of transport, much that the hospital has to offer, both of consultative advice and of treatment, is being made available to these patients without ever admitting them to its wards. We would lay great emphasis on the need for utilizing to the full all such resources as may protect the acute hospital bed from use for other than its proper purpose.

Administrative Procedure of Admission to Beds.—The economical use of beds (i.e., avoidance of wastage by non-occupation between discharges and admissions and by overlengthy stay) is largely dependent on efficient administrative arrangements for admissions, and on the existence of sound contacts between the administration and the clinicians in charge of beds. Regional bed bureaux perform a most useful function in dealing with emergencies; but admissions, or acceptance of responsibility for alternative arrangements, should normally be undertaken at management committee (or where necessary at component unit) level, and thus the group would be imbued with a sense of its responsibility to the sick in the geographical area which it is intended to serve.

The Hospital Group.—It may well be that the principle of grouping provides the National Health Service with its greatest opportunity for improvement in hospital resources. The initial grouping of hospitals—to enable the Service to operate on the appointed day—was necessarily undertaken at short notice. It is therefore reasonable to hope that the groupings themselves, and the purposes for which beds may have been initially allocated, may be subject to review and readjustment in the light of experience. Since one at least of the purposes of grouping hospitals is to provide an integrated and more comprehensive service, it follows that the group must within itself provide, *inter alia*, suitable alternative accommodation for patients requiring admission but not admission to an acute ward.

For example, it may be possible to increase the output from the group as a whole by the provision, even from its existing resources, of beds in recovery annexes or convalescent hospitals so as to make the fullest possible use of the specially equipped and staffed acute beds. Or, again, it may prove necessary to supply a group with ancillary accommodation—e.g., of hospital-recovery type—at present non-existent. And, yet again, the question of invalid settlements and long-stay annexes for the chronic sick and of their contiguity to one or more of the well-equipped hospitals in the group requires urgent consideration and solution. Underlying all such considerations is the necessity on the one hand to have regard to the convenience of the patient—e.g., by avoidance of long journeys and of undue separation from relations—and on the other hand to facilitate continuity of medical supervision of his case.

The group can in our view greatly increase not only its total output but even its range of service if individual clinical departments have a balanced complement of acute and recovery (or long-stay) beds—not necessarily all within the same curtilage

*This memorandum was originally prepared for, and is now under consideration by, the B.M.A. Committee on Nursing, of which the joint authors are members.

—to meet their particular requirements. This is supported by experience gained in the thoracic unit at St. Helier Hospital.

Nurse-Staffing for the Hospital Group.—A further consideration in the matter of grouping which is of fundamental importance in connexion with the nursing problem is that the group must be of such size and be so arranged that it is reasonably self-contained for its purpose, but able to regard itself as one entity. Each group should therefore provide its own nurse-training school. Since the formation of a particular group may be much affected by local conditions it would be unwise to dogmatize on such matters as maximum size. What does matter—and in particular from the point of view of nurse-staffing—is that the group should be a close-knit body with a strong *esprit de corps* and a full sense, both at its centre and throughout its components, of a common duty to the neighbourhood which it serves. This set-up will facilitate the circulation of the nursing staff throughout the component units of the group in a manner comparable with the established practice of posting from one ward to another in the same hospital.

Where a group is centred round a "special" hospital the position regarding its nurse-training school must remain as dealt with in Paras. 22-23 (Part III) of the memorandum on "Recruitment and Training of Nurses." Where for some reason a group is not self-contained interworking between contiguous groups may be necessary, particularly for certain types of specialized investigation and treatment; but such interworking should *not* involve the transfer of nursing staff from one group to another.

The higher output obtainable from the acute wards by greater selectivity of admission, the provision of recovery annexes, etc., would, generally speaking, involve an increase in the nursing staff of the acute wards which in some cases would be substantial. This need for more staff in one section may, however, be more than offset by economies in nurse-staffing in other directions, as shown in Section B below.

B. Economical Use of the Nurse

This part of our memorandum deals with a more difficult aspect of the problem, and one which is more open to controversy. We therefore approach it from the point of view of exploration.

The Nature of Nursing

It is impossible to approach the matter of the economical use of the nurse without some agreed conception of the essential nature of the nurse's work. No definition has so far been offered in reply to the questions so often asked recently on precisely what nursing is and what is the function of the nurse.

Without attempting a precise definition we would suggest that nursing comprises two main and distinct functions: one is to minister to the patient's comfort; the other is to assist the doctor in safeguarding the patient and in the progress of the case. It is on this conception of nursing that we base the considerations which we venture to submit below. Nor is this basis merely hypothetical, since it accords with actuality. To illustrate the point, at one side of the scale there are untold numbers of infirm and sick people who are daily nursed in their own homes by relations or friends. The services thus rendered relate, though not exclusively, to requirements connected with the patient's comfort. This contrasts with the other side of the scale, where the highest degrees of nursing skill are called for.

It follows, therefore, that the division of nursing function as between comfort and skill enables nursing requirements themselves to be subdivided into those of skilled nursing and unskilled nursing. It therefore becomes possible to consider in practical terms how waste of skilled nursing can be avoided by ensuring that it is applied only where required and that full use is made of unskilled nursing wherever appropriate.

Is it possible, as a primary step towards the economical use of the skilled nurse, to approach the problem of nursing staff in the wards—no matter what their type—in such a way that the highest degree of nursing skill is combined with the unskilled devotion met in the home? In our view this is possible, and is indeed inevitable; but its achievement depends upon factors which may involve a reorientation of view and may even

be regarded by many as revolutionary. For example, the skilled nurse will need to have a greater realization of the two-sided nature of her work. One side, of course, is the exercise of her skill on a particular patient requiring it; the second side is the avoidance of wasting her time on duties which fall within the competence of others not possessing her skill. This involves a conscious realization of her nursing duty as a supervisor of unskilled nursing and is the starting-point in the economy of effort, since unless she is trained in the art of delegation the skilled nurse cannot make the greatest or the most effective use of her own training and experience.

These considerations apply strictly to economy of skilled practical bedside nursing and are not intended to refer to ward administration or to imply the up-grading of a staff nurse into a junior ward-sister.

Nursing Aides

It being established that the skilled nurse must herself exercise a discretion regarding which of her patients require more of her personal attention and which require less, there follows the need to provide her with appropriate personnel to whom she can delegate. Under no circumstances must the nursing aide be confused with the domestic or semi-domestic ward worker. His or her alignment should, on the contrary, be intrinsically with the ward nursing team. A proper—even safe—use of the nursing aide cannot, however, be made unless the right type of recruit is attracted to the work (quite as much a question of status as of pay), and unless the general orbit of the aides' duties is clearly demarcated and they receive adequate encouragement and a short preliminary training. Actual experience of their satisfactory use appears to have been obtained by hospitals that have seriously addressed themselves to the experiment.

Non-Nursing Duties

We have avoided referring to matters of smaller moment, obvious though they are in themselves: for example, elimination of the practice of employing nurses on non-nursing duties, such as chaperonage and certain administrative work. We would, however, make passing reference to the importance of a memorandum by King Edward's Hospital Fund (*Lancet*, Aug. 14, 1948, p. 266) on the loss from hospitals of newly trained staff, and to their plea for the employment of suitably trained non-nursing personnel in the public health nursing field wherever possible.

Conclusion

The idea that a person without a nursing qualification should be allowed, either nominally or actually, to undertake any form of nursing duty may at first glance be distasteful to many. At the risk of repetition, however, we would once again stress the fact that, on account of the woman-power position alone, nursing requirements cannot be met unless measures of this kind are studied, evolved, and implemented. It is sheer necessity that is the spur. Surely it is better to make a virtue of necessity and to solve the problem by its frank realization.

Summary

The problem of nurse-shortage can be solved only by multilateral approach.

Two aspects of this problem which have as yet not received due attention are the economical use of the nurse and the economical use of the hospital bed.

The economical use of the hospital bed can be achieved by: (a) the conception of a hospital as a polyclinic with beds rather than as a ward-nucleus with ancillary facilities; (b) economy in the use of beds in well-equipped hospitals by a greater selectivity of admissions; (c) the provision of a balanced bed complement—within the group—e.g., acute, recovery, and long-stay; (d) the provision of short-stay hostels in conjunction with out-patient departments; (e) the provision of various kinds of accommodation for the chronic sick of all ages and for the elderly and infirm; (f) efficient administrative procedure for admissions to avoid wastage of beds.

The group must form one entity, as this is essential to: (a) *esprit de corps*; (b) nurse-training and staffing; (c) its shouldering of responsibility for the sick in its area.

The economical use of the nurse may be achieved by: (a) recognition of the fact that not all nursing is skilled nursing; (b) recognition that the duties of all skilled nurses should include a supervisory function; (c) provision of appropriate personnel to whom unskilled nursing can be delegated under supervision; (d) recognition of the importance both of the training and of the status of the nursing aide.

As official woman-power statistics show, the problem of nurse-shortage demands a fresh outlook if it is not to remain intractable.

THE KING'S HEALTH

OPERATION FOR LUMBAR SYMPATHECTOMY

The following bulletin was issued from Buckingham Palace on March 8:

The King's general health continues to be excellent.

In the left leg the flow of blood has been restored in the main arteries to a satisfactory degree.

In the right leg the main artery is still obstructed and the circulation is being carried on, less efficiently than in the left leg, through a collateral circulation.

With a view to improving the blood supply to the right foot, and to safeguard this for the future, we have advised his Majesty that the operation of lumbar sympathectomy should be performed on the right side. The King has accepted this advice and the operation will be performed at an early date.

MAURICE CASSIDY.	J. R. LEARMONTH.
THOMAS DUNHILL.	J. PATERSON ROSS.
HORACE EVANS.	JOHN WEIR.

On Saturday, March 12, the next bulletin stated:

The operation of lumbar sympathectomy was performed on the King at 10 a.m. His Majesty's condition is entirely satisfactory.

MAURICE CASSIDY.	C. J. LONGLAND.
THOMAS DUNHILL.	J. PATERSON ROSS.
HORACE EVANS.	A. J. SLESSOR.
JOHN GILLIES.	JOHN WEIR.
J. R. LEARMONTH.	

A further bulletin, issued on Saturday evening, read:

The King has had a restful day. Temperature, pulse, and respiration rate have not varied from normal, and his Majesty's recovery from the operation is proceeding smoothly.

MAURICE CASSIDY.	J. R. LEARMONTH.
THOMAS DUNHILL.	J. PATERSON ROSS.
HORACE EVANS.	JOHN WEIR.
JOHN GILLIES.	

A bulletin issued on Sunday morning stated:

During the night the King has had periods of sleep. Temperature, pulse, and respiration are normal. His Majesty's condition and progress are those usual after lumbar sympathectomy.

MAURICE CASSIDY.	J. R. LEARMONTH.
THOMAS DUNHILL.	J. PATERSON ROSS.
HORACE EVANS.	JOHN WEIR.
JOHN GILLIES.	

Further bulletins issued on March 14 and 15 confirmed that the King's general condition remains satisfactory.

It is understood that the operation was performed by Professor J. R. Learmonth, professor of surgery at Edinburgh University, with Professor J. Paterson Ross, professor of surgery at London University. The anaesthetist was Dr. John Gillies, director of the department of anaesthetics at the Royal Infirmary, Edinburgh. Professor Learmonth had the assistance of Dr. A. J. Slessor, medical superintendent and assistant surgeon to the Western General Hospital, Edinburgh, and Professor Ross was assisted by Dr. C. J. Longland, first assistant in the surgical professorial unit of St. Bartholomew's hospital.

Professor Learmonth remained at the Palace throughout Saturday night and Sunday.

TUBERCULOSIS IN ENGLAND AND WALES

MINISTRY STATEMENT

A recent statement issued by the Ministry of Health points out that the present situation regarding tuberculosis in England and Wales needs to be judged against the background of the progress made during the period between the two world wars. Between 1918 and 1939 the number of deaths from all forms of tuberculosis fell from about 58,000 in 1918 to about 25,600 in 1939. Then in 1940 and 1941 the number of deaths rose to over 28,000. This increase, however, was checked, and the figures for 1942, 1943, and 1944 were approximately 25,500, 25,600, and 24,100. The fall continued in 1945 and 1946, when deaths numbered 23,955 and 22,847, respectively, rising slightly in 1947 to 23,550.

These mortality figures are the most reliable criterion of the trend of tuberculosis, as against the numbers of notifications of the disease, which are not necessarily an accurate reflection of its incidence. It is observed, however, that the numbers of deaths in the war years, unexpectedly favourable though they were, were higher than they would have been if the pre-war rate of decline had continued; the number of notifications rose above and still remains above the pre-war level. In 1918 the total number of formal notifications was about 90,000; in 1938, about 50,000; and it has since been as follows:

1939	..	46,000	1944	..	54,000
1940	..	46,600	1945	..	52,000
1941	..	51,000	1946	..	51,300
1942	..	52,600	1947	..	51,700
1943	..	54,000			

The relation between respiratory and non-respiratory types of tuberculosis, which hitherto has shown no substantial deviation from year to year (although such a factor as increasing pasteurization of milk may materially affect the incidence of non-respiratory tuberculosis as time goes on), may be gauged from the fact that in 1947, of the total of 23,549 deaths, 20,156 were due to respiratory tuberculosis.

The admission of patients to tuberculosis institutions for treatment with reasonable promptness continues to present a serious problem. The reason for this is not the lack of sufficient accommodation but the persisting shortage of nurses. The number of patients under institutional treatment at June 30, 1948, was about 29,200, while the number on the waiting-lists for such treatment was about 9,000. The number of new patients who came on the registers of tuberculosis dispensaries in the quarter ended June 30, 1948, was about 13,000.

Developments in the Tuberculosis Service

The introduction in 1942 of mass miniature radiography to detect respiratory tuberculosis in its earlier stages constituted an important advance. Owing to the wartime limitations on the production of the apparatus and on the availability of medical man-power it has been possible to provide these mass radiography units only gradually in selected areas of the country. By Dec. 31, 1948, there were 37 of these units in operation in England and Wales, and the Ministry itself operates one at a fixed centre in London as a training and research unit. By June 30, 1948, about 2,500,000 persons had been examined, of whom approximately 94% were found normal at the time of examination. The number of cases in which clinical investigation following evidence of abnormality in the miniature film led to diagnosis of active tuberculous conditions was approximately 9,564, or between 3 and 4 per 1,000 of all the persons examined.

Under the National Health Service Act the responsibility for the tuberculosis treatment services—namely, institutional and out-patient services, including the mass radiography service—passed on July 5, 1948, from county and county borough councils to the regional hospital boards, though the local authorities remain responsible as the local health authorities under the Act for the preventive and care and after-care work in relation to tuberculosis.

Under the National Assistance Act, persons who suffer a loss of income in order to undergo treatment for respiratory tuberculosis and need financial help over and above such statutory

payments as national insurance benefit and family allowances are able to obtain this through the National Assistance Board. The main object of this assistance is to afford a reasonable standard of maintenance for the patient and his dependants during the period of treatment so as to encourage the sufferer, for both his own and the community's sake, to give up work to undergo early treatment.

Nova et Vetera

HOW DID SCIENCE BEGIN?

Many must wonder why medical historians continue to pour out investigations of the writings of Vesalius. They must often ask, "Are they not coming to an end of Vesalius?" The simple answer is "No." This review of Professors Saunders and O'Malley's book* may explain why this is so.

It is quite obvious now to us all that the value of any theory concerning natural events or objects rests on facts established by observation and on their adequate presentation. But, strange as it may seem, this was by no means evident before the seventeenth century, when Francis Bacon and René Descartes delivered their messages. Till then men were educated in the scholastic tradition. This taught them that, in matters of the world of the senses, having made sure of the premises, they might safely reason therefrom for an indefinite time and—provided of course that they had made no error of logic—they might then return again to the world of the senses and safely apply the conclusions that they had reached.

One reason why they thought along such lines was that they conceived the world of the senses to be much simpler than we now know it to be. Another reason was that they did not realize how extremely difficult it is to be sure of the premises. But for these reasons, among others, research into the supposedly simple scheme of Nature afforded little temptation to men of subtle minds. These naturally preferred the infinite possibilities of theological, ethical, philosophic, or linguistic discussion. They considered it a less worthy vocation to investigate the realm of things than the realm of thought. Perhaps they were right. But it is certainly true that not only does research in the world of things yield more rapid and more tangible results, but also that history has shown that it has profoundly influenced our conception of the world of thought.

Now this "scientific" view did not occur suddenly to the men of the seventeenth century. On the contrary, for at least a hundred years before Bacon and Descartes there had been men who were feeling their way in that direction and yet failing to express their conclusions with clearness or to apply them with any considerable success. But in this matter 1543 was an *annus mirabilis*, for within a few days of each other the aged Copernicus (1473–1543) sent out his treatise *On the Circulations of the Celestial Spheres* and the youthful Vesalius (1514–64) issued his magnificent folio *On the Workings of the Human Body*. These are the two foundation works of modern science. The outlook of Vesalius, under by 41 years, is the more modern of the two. Though intellectually enmeshed in the difficulties which the lack of a clearly formulated scientific method had woven, as our authors truly say, he produced a great work of research in the modern sense. Anything that helps to explain how this came about is thus significant not only for medical history but also for the history of science and, even more, for history itself, since science has been a major factor in the moulding of the modern world.

It is therefore extremely important to trace, completely and exactly, all the processes—mental, social, personal, political—by or through which Vesalius, starting as a scholastic, became a scientific inquirer. He is the ideal subject for the investiga-

tion of the beginnings of science. The materials exist, but their elucidation presents very special technical difficulties. With the nature of these we are not immediately concerned, but no one has made more significant contributions to their solution than Professors Saunders and O'Malley. They would be the first to allow that it must be many years before the problems with which they deal are finally resolved. The obstacles are far greater than earlier writers on Vesalius imagined, and very much more work is needed before the embryology of the inductive method can be set forth at all adequately. This book completes a stage in this task—a stage which its authors are uniquely equipped to accomplish. They have done a real service both to history and to the understanding of the evolution of the modern mind.

The earliest works of Vesalius are an edition of a work on anatomy by one of his teachers and a set of anatomical diagrams. Both appeared in 1538, and show him as a fairly typical scholastic, basing his views chiefly on his teacher's Latin translations of Greek texts of Galen. But in the *Bloodletting Letter* of 1539, which Professors O'Malley and Saunders now translate, edit, and annotate, he advances a little on the scholastic position. Here he asks a first tentative question, "Whether the method of anatomy could corroborate speculation." This letter is therefore transitional, occupying the period of the scientific adolescence of Vesalius, bridging the interval between the frankly Galenic anatomy of his earlier recension of Guinter's *Institutiones Anatomicae* (1538) and the *Fabrica* (1543), the first positive achievement of modern science.

In the history of modern science the study of structure necessarily preceded that of function. Vesalius was without the illumination that came with Harvey's disclosure of the circulation in 1628. His *Letter* of 1539 is based on the error, derived from Galen, that the venous system is independent of the arterial and receives no contribution from it. This view was the basis of a practice of venesection which, though developed by him on a more correct anatomy than that of his predecessors is physiologically as ill-founded as was theirs. Nevertheless Professors Saunders and O'Malley have been able to elucidate many incidental references in the course of this *Letter* that concern the activities and personal relations of Vesalius. These throw light on the central problem of his mental evolution. Our knowledge of the life and thought of Vesalius, and with it our conception of the growth of the "scientific idea," have thus been significantly forwarded by this important and ably drafted little monograph.

CHARLES SINGER.

Reports of Societies

HEALTH CENTRES

A meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine, held on March 7, was devoted to a discussion on "Health Centres." Sir ALLEN DALEY presided. A model and plans of the projected L.C.C. Woodberry Down Health Centre were exhibited. This was the centre described in our issue of Jan. 29 (p. 191).

Architectural Considerations

Mr. W. T. DURNFORD, F.R.I.B.A., of the Architects' Department, L.C.C., said that the general plan in London was eventually to have a health centre to every two neighbourhood units, a unit comprising a population of from 6,000 to 10,000. When the scheme was completed no resident in the county of London would be living further than one mile from a health centre. One difficult architectural consideration was the number of floors which should be planned. Medical practitioners were anxious to be "in on the ground floor," but so were all the other services—which was impossible. Another planning question was whether the approach to the centre should be by single entrance from a large central space or by a separate entrance for each unit in the centre. At Woodberry Down the latter method had been chosen.

* *Andreas Vesalius Bruxellensis. The Bloodletting Letter of 1539. An annotated Translation and Study of the Evolution of Vesalius's Scientific Development.* By John B. de C. M. Saunders, F.R.C.S., and Charles Donald O'Malley. Limited Edition. (Pp. 94. 21s.) London: Wm. Heinemann Medical Books.

It had been decided to place the doctors' and dentists' units on the main frontage of the building with access from the chief traffic road. This might have the disadvantage of traffic noises, but these could be minimized by the use of double windows, by setting back the building from the road, and by judicious tree planting. Parking facilities for patients' cars and garage space for the cars of doctors were a necessity. The six general practitioner suites were on the ground floor and were approached by corridors from the main entrance. The temptation to make a single large waiting-room had been resisted, and there would be small individual waiting-rooms for the patients of each doctor. These rooms would each accommodate about twenty patients, the planning being on the assumption that the number of registered patients per doctor might stabilize at 2,500, and allowance was also made for a certain number of private patients. The superficial area of the consulting room was 168 sq ft, and opening from it would be an examination-room equipped with couch and lavatory basin. The patients would be able to leave without returning to the waiting room.

Other features of the Woodberry Down building would include an isolation room on the ground floor. On the first floor there would be a minor operations room, a room for ophthalmic treatment and a room in which the doctors could carry out any of the simpler pathological investigations without the attendance of a pathologist. There would be two dental surgeries from which access would be obtained to x-ray apparatus elsewhere. A small drug store was provided for the immediate needs of the unit, but not for dispensing practitioners' prescriptions. A lecture hall of 800 sq ft was planned. A foot clinic would be included, with its own small waiting-room and a room for examinations. A suite would be devoted to ultra-violet light therapy, and there would be a unit for orthopaedic and remedial exercises and a child-guidance clinic. There would also be common-rooms for the staff. The cost of the Woodberry Down centre was expected to be 5s 6d per cu ft (leaving out furniture and movable equipment), or £3 10s per sq ft of area.

Value of Partnership

Dr A. TALBOT ROGERS, chairman of the Health Centre Committee of the B.M.A. and vice chairman of the Health Centre Subcommittee of the Central Health Services Council, said that the B.M.A. Committee had been set up with the idea of trying to discover what experience had shown to be the most satisfactory form of medical practice. In the course of a survey a large number of doctors practising under different conditions had been interviewed. The best type of practice was held to be a partnership practice conducted from a communal surgery. Such a system gave the doctors opportunity for consultation with each other, it stimulated friendly competition, it enabled the more experienced practitioner to help the younger man and at the same time it enabled the young man straight from the medical school to rejuvenate some of his elders. This combination of three or four or perhaps half a dozen doctors working together had enabled such doctors to provide an increased number of consultation hours; it also gave the patients a choice of doctor, if they wished, for different illnesses or different members of their family. The partners were also able to cover the temporary absence of any of them without the introduction of a strange doctor.

It was found that partnerships on the whole were better equipped (instruments, books, etc.). Moreover, an amicable working partnership did attract patients. If an extra partner were taken in on account of the large amount of work it was soon found that the overplus of work was absorbed and that the number of patients grew. The partnership system was not unpopular to say the least of it, among patients. Further, it made it possible economically to use a greater amount of auxiliary and secretarial help.

During the last thirty years there had been a separation between the service of the general practitioner and the preventive services of the local health authority. It was desired to reintegrate those two sides of medical practice. The health centre would include provision for maternity and child welfare service, the school medical service, etc. It was a little problematical whether the midwives could also work from there. It

was desired to make the centres as little institutional as possible. Too great a modelling of the health centres on the lines of the local authority clinic would be enough to upset the relationship. Therefore he welcomed the idea that each doctor should have his own suite and that there should not be one large common waiting hall. He doubted whether the health centre would furnish a good opportunity for the health education of the public. As he saw it, the patients coming to these health centres to see their own doctors were unlikely to be coming regularly, and therefore there would be little opportunity for the use of such methods as a series of posters leading one to another. Moreover, they would alter the atmosphere of the whole place, making it like an exhibition hall. Lectures might be given to invited groups, but not ordinarily to the patients waiting to see their doctors.

So far as the diagnostic facilities, particularly pathological and radiological, were concerned, he thought that these should be provided not at health centres but at hospitals. If easy access to hospitals could be provided it was better that such diagnostic facilities should be available there. Again, on the question of physiotherapy, the setting up of such a unit at Woodberry Down might mean some wastage of staff. The physiotherapy department was better placed at the hospital. He hoped that the health centre might be used for the education of young practitioners and medical students.

Doctors Working Together

Dr FRANK GRAY, secretary of the London Local Medical Committee, who was introduced as "a specialist in general practice," explained that he was speaking only for himself and not for his committee. He believed that in a new departure of this kind they must learn as they went along. They would undoubtedly learn from their mistakes and from their successes—if they had any. The men and women who worked at the centre were more important than the bricks and mortar. It was rather a pity that in their discussion that evening they had started with the building. Was it wise to force doctors into a building prepared for them? Was it not better to build the edifice around the doctors?

The natural starting point was a number of doctors working together. What followed from that conception? To his mind it was essential that doctors should work in partnership. Supposing they did not work in partnership, what about the new patient? The health centres themselves, with their "chromium plating and platinum blondes," would attract patients. Patients would come and say, "I want to join the health centre," and when asked, "Which doctor do you want?" they would not be able to say. If the doctors were in partnership that did not matter. Then what about the surgery hours if the doctors were not in partnership? Would each of them stay on until the other fellow had gone home? How was any one doctor to express the views of his colleagues to the local health authority on the running of the centre unless they were all in partnership? Even angels might be tempted to put their own preferences before those of their colleagues in such circumstances.

As for the use of space, it was possible, said Dr Gray, that the era of unlimited spending might not last for ever. If that was so the question of the use of space would have to be considered much more closely. At present, with great respect to the L.C.C., the idea seemed to be not only one room for each individual doctor but one room for each individual whatever function he was performing. Somebody would ask one day, "Is all this building really necessary?" It meant unlimited money, a pre-Service mentality, and vested interests, but unlimited money would not last for ever, the pre-Service mentality would die out in the course of years and as regards vested interests the larger vested interests in sale and purchase had been abolished, so that it was not unreasonable to suppose that the smaller also might be faithfully dealt with. Supposing this was not a public enterprise, but just a partnership of several doctors in a large surgery, was it supposed for a moment that they would go in for all these rooms? They would share the consulting-room. They would not all want to be there at the same time. What did they do in Harley Street?

Then he thought they must not lose sight of the advantages of the doctor's private house. They might not know what to do

in this new set-up, but they did know what not to do—namely, not to imitate the hospital out-patient department. It would be very nice to have an appointments system. The room could then be smaller and cosier still, but in general practice that system would not work. As one who had worked in a general practice for some time, he knew that they got a large number of patients who always wanted their own particular doctor, but a number also did not want or need a particular doctor, they just came for the certificate. In a partnership that was easy to arrange; without a partnership it would be an appalling difficulty.

He could not resist a word on physiotherapy. Physiotherapy was the best method devised for the activation of neurosis. They did not want it. He noticed also that at Woodberry Down there was to be a nice little apartment for the night-duty doctor. What was the idea of a night-duty doctor at a health centre? Why have one? The only useful purpose would be for night consultations. If it was a case of being called out at night it would be just as well to summon the doctor by telephone from his home a mile away as from his bedroom a few hundred yards away in the same building. Patients who attended at the health centre were not usually the people who wanted attendance during the night, and, as for accidents, these were best dealt with at the hospital. He could not see any reason for the night-duty doctor. What was wanted was a really intelligent night caretaker who would be able to put a messenger in touch with the doctor direct.

General Discussion

Dr. C. O. S. B. BROOKE (Finsbury Health Centre) said that his experience in Finsbury was that the physiotherapy clinic did not stimulate neurosis and it had a great value, particularly in relation to the aged and infirm. A few years ago, in discussing health centres, the accent was on positive health, whatever that might mean, but now it appeared that such centres were for curative medicine. They ought to be called "general practitioner centres." It had been assumed that patients would be ready to go a mile to the health centre, but that was optimistic. In London people were not willing to go quite as far as one mile. There was no part of Finsbury which was as much as one mile away from the health centre, but they had difficulty in getting people to attend from the remote parts of the borough. Previously he had had experience in County Antrim, and he found less difficulty in getting people to go 20 or 30 miles to their county town than in getting Finsbury patients to go to University College Hospital.

Dr. H. C. BOYDE (West Ham) noted that there was lacking in the present discussion any sense of urgency. Nobody appeared to realize that in the Health Service the machine was creaking in many of its joints, and the resulting strain was being borne fundamentally by the men in general practice. Whatever difficulties there might be in hospital organization, the simple fact concerning the general practitioner was that he had now more difficulty than ever before in getting his patients into hospital. He believed that there could be no improvement in the quality of general practice without a health centre. In West Ham they had worked out a plan for a health centre with six doctors, two dentists, a number of nurses, a physiotherapist, and certain technicians. The problem was to get them all together.

The "physiology" must come first and the "anatomy" afterwards. The West Ham scheme, which planned to place the health centre in an adapted building and brought in the administrative side of local health authority services, including maternity services, home nursing, a minor laboratory, and some elementary ancillary facilities such as a chiropodist, was estimated to cost £15,000. It had been fully endorsed by the general practitioners, the local executive council, the medical officer of health, and the borough architect, but the Ministry had turned it down on the flippant ground, as they thought it, that it would use 40 tons of steel. They were now submitting revised plans, according to which only six tons of steel would be needed, and it was hoped to start in three months from now.

Dr. J. A. SCOTT (L.C.C.) pointed out that it was the local authority which provided the "anatomy" and somebody else who provided the "physiology," and he rather thought that

any "physiological" proposition would be refused unless there were already a "skeleton" fit for the work. It was necessary therefore to think about the building and to try to make a reasonable framework and equipment.

The PRESIDENT said that the question of a pharmacy at the health centre was one of considerable difficulty. At Woodberry Down there appeared to be a number of chemists' shops in the vicinity, and it was thought that if there was a dispensary at the health centre with people queueing up it would rather suggest the out-patient idea. On the question of the night doctor he wondered whether the doctors working at the centre would be prepared to live, as Dr. Gray had suggested, only a mile away.

Dr. GRAY, in reply, said that Woodberry Down was an excellent "pilot model." If a start had been made with a bad health centre in London it might have damned the movement in the whole country. As for the night doctor, he thought the doctor should not live more than one or two miles away from the centre, and the executive council should discourage doctors living at a greater distance.

Dr. ROGERS said they all agreed that they did need prototypes like Woodberry Down. He also pointed out the great advantage to that hardworking member of the doctor's practice—namely, the doctor's wife—in having her home uninvaded and the work of the practice transferred to a centre.

Mr. DURNFORD said there was nothing "flippant" in turning down a scheme which took 40 tons of steel. It was not realized how extraordinarily scarce were building materials and labour. Adaptations were in the long run much more costly and took more time than new buildings and were seldom satisfactory. It was better to concentrate on a smaller number of new buildings than on a large number of adaptations.

WOODBERRY DOWN HEALTH CENTRE

On Wednesday, March 16, at 11 a.m., Mr. Aneurin Bevan cut the first sod of the site of the Woodberry Down Health Centre at Stoke Newington. The new centre is to cost £187,275. It will be the first of its kind in London, and the first in the whole country to be approved by the Minister of Health. Under one roof there will be ante- and post-natal clinics, a child-welfare clinic, a school treatment centre, other local health services, and general practitioner and dental services.

Five units will be accommodated: a medical practitioners' and dental surgeons' unit, a school health unit, a child-welfare unit, an antenatal unit, and a remedial exercises and child-guidance unit.

The L.C.C. will staff the centre with receptionists, dental technicians, and others, and the London Executive Council will arrange for the attendance of general practitioners and dental surgeons. The L.C.C. will also staff the clinics and the school treatment centre. Doctors and dentists attending the centre will, with the L.C.C. divisional medical officer, form a professional committee to organize the general medical and dental services and to make recommendations to the body responsible for running the centre as a whole—the L.C.C. Divisional Health Committee. To the east of the health centre a day nursery is to be built.

The Ministry of Health announces that a working party has been appointed to investigate the timings of dental operations. The working party has been asked to ascertain the average chairside time taken by general dental practitioners in England, Wales, and Scotland (1) in the National Health Service and (2) in private practice to complete each of the types of dental treatment set out in Part I of the First Schedule to the National Health Service (General Dental Services) Fees Regulations, 1948, excluding any items for which it is impracticable to establish an average time—e.g., orthodontic treatment. The working party consists of: Mr. William Penman (chairman), a past president of the Institute of Actuaries; Mr. A. Macgregor, L.D.S.F.P.S.; Mr. S. Donald Cox, of the British Dental Association; Mr. J. Lauer, L.D.S.R.C.S., of the Public Dental Service Association; and Mr. A. H. Condry, of the Incorporated Dental Society. Dentists selected by the chairman will be invited to assist in the investigation.

Correspondence

Occupational Diseases of the Lens and Retina

SIR.—It was on Nov. 13, 1902, nearly forty-seven years ago, that Dr. William Robinson read his paper on "Bottle-finishers' Cataract" at a meeting of the Northumberland and Durham Medical Society in Newcastle-upon-Tyne. The paper, with an illustration, was published in the journal of the Society the following year. I remember the occasion so well, and was disturbed that this original communication should have received such a lukewarm reception. William Robinson was then a practitioner-surgeon in Sunderland on the staff of the Eye Infirmary of that town, as well as the General Hospital, and was remarkable in that he had obtained his F.R.C.S.(Eng.) while in general practice in what was then a remote country township in Durham. Shortly afterwards he migrated to Sunderland.—I am, etc.,

Taplow, Bucks.

G. GREY TURNER.

Pain in Childbirth

SIR.—The publication of the report of the Medical Women's Federation on pain in childbirth (*Journal*, Feb. 26, p. 333) comes at an opportune time. The important point that I want to emphasize is the large number of such cases where chloroform was used, when 194 out of the 222 medical mothers who received it "found it perfect." Chloroform has been in general use in maternity work for 100 years. I can vouch personally for its use for 50 years—(1) when in charge of a large hospital maternity district; (2) in a large single-handed maternity general practice; (3) when in charge for years of the teaching of anaesthesia in the same hospital; (4) when the maternity ward was opened; (5) as a specialist giving many such anaesthetics in ordinary and abnormal cases for many obstetricians in their private work in and around London; and (6) finally in the country for a large scattered rural practice.

Personally, I have not met any difficulties. I was co-opted on the Committee of the Royal College of Obstetricians and Gynaecologists after I had given the College a registered fool-proof Junker which, in the hands of unqualified people, was considered by the Committee as "reasonably safe." This safety Junker was registered, as the measurements had to be carefully complied with, and Mr. Charles King did this at my request before presentation to the R.C.O.G. for trial.

Recently Dr. John Gillies, of Edinburgh, wrote a paper for *Anaesthesia* giving most interesting figures of the use of CHCl₃ in Scotland. Experimentally I saw in the U.S.A., in 1923, auricular and ventricular fibrillation produced in tracheotomized dogs with their hearts exposed, and was much impressed with the large amount of CHCl₃ needed to produce it. I was not impressed with McKesson's N₂O anaesthesia, even when given by himself. Why, then, was CHCl₃ condemned by the R.C.O.G. for use in a fool-proof machine? Simply on evidence of delayed CHCl₃ poisoning in three inexcusable cases, and in one fatal case, when 120 minims (7 ml.) of CHCl₃ was given in a single dose on a mask! (6 glass capsules=2 drachms.) Analgesia is not fully understood, far too large doses are used, and it is possible to control the dose and limit the time of inhalation mechanically.

At the Annual Meeting of the B.M.A. at Cambridge last July, when I was President of the Section of Anaesthetics, we held a most successful combined meeting with the gynaecologists on analgesia. I was able to keep the discussion an open one. I was pleased to hear many people admitting the use of CHCl₃, which is more than they did at Oxford in 1936, although I knew they were constantly using it. Then it was only when my old friend Beckwith Whitehouse (who was in the chair) called upon me towards the end of the meeting, and by previous arrangement, that CHCl₃ was even mentioned.

Trilene is still *sub judice*, but the preliminary communications read at Cambridge by the two research scholars of the Association of Anaesthetists working at Guy's gave promise of useful information to come.

This is a plea for the better understanding of CHCl₃, analgesia and its teaching to the untrained, with proper safeguards.—I am, etc.,

Petworth, Sussex.

Z. MENNELL.

SIR.—As a midwife, may I comment on the report of the Medical Women's Federation as printed in the *Journal* of Feb. 26 (p. 333)?

(1) The very high proportion of specialist obstetricians booked for deliveries (i.e., 318 out of 425) is obviously not representative of the country as a whole. This would not matter if the result of booking this type of accoucheur had not produced an abnormal number of forceps deliveries for apparently unknown causes. (It is tempting to suggest possible reasons.)

(2) These instrumental deliveries surely affect the number and types of anaesthetics administered. The handling of an apparently normal case resulting in a forceps delivery could equally affect the mother's desire for "more anaesthetic."

(3) I doubt if such detailed accurate information can be obtained ten years after the event.

(4) 69% of perineal tears among the primiparae is dismissed as "the situation . . . is on the whole satisfactory." I can imagine no midwife considering such a total so complacently.

My conclusion is that a far more useful result, combining detailed knowledge of drugs used and the conduct of the labour with a more widespread and normal engagement of accoucheurs, could be obtained if a similar questionnaire could be sent to all married midwives who have had children within the last five years.—I am, etc.,

London, N.6.

N. C. GILBERT.

SIR.—As you say in your leading article (Feb. 26, p. 356), some disquieting facts emerge from the report of the Medical Women's Federation on the relief of pain in childbirth, published in the same issue at p. 333. These medical women presumably selected their medical attendants for their confinements with especial discrimination, and over two-thirds of them were attended by obstetric specialists. And yet the report shows that they had a forceps rate as high as 27% for first births, perineal repair was required in no less than 43% of normal deliveries, and there is still an astonishing addiction to chloroform as an anaesthetic. Are these the same obstetric specialists who are trying to persuade us that the general practitioner is not fitted to undertake normal midwifery?—I am, etc.,

Wivenhoe, Essex.

WALTER RADCLIFFE.

Painless Childbirth—A Suggestion

SIR.—Nearly thirty years ago, owing to a succession of fatalities under anaesthesia, reported to a Board of which I was a member, I commenced a tentative investigation in search of a safe anaesthetic. Various unsaturated hydrocarbons, chloro-derivatives, and ethers were tested on myself, those not commercially obtainable being prepared by me in the department. The investigation had unfortunately to be abandoned, and opportunity to continue it was not found before my retirement. Of the substances tried, propylene pleased me most: 15% in 35% oxygen produced loss of consciousness; 12% did not; 34% caused intoxication in one minute and loss of consciousness in three minutes. No ill-effects were experienced. The lower homologue, ethylene, required 60% concentration with 40% oxygen to produce unconsciousness; only 35% of the less saturated acetylene was necessary; both were more effective than 80% nitrous oxide with 20% oxygen. It is necessary to emphasize that the propylene must be pure. Inhalation of the next higher homologue (a mixture of two butylenes), prepared without sufficient care, produced serious effects. The unsaturated hydrocarbon series stopped at the butylene stage, for one of the many isomers of amylene, the next homologous series, had been used (under the name pental) for some time previously as an inhalation anaesthetic, and apparently without decided untoward actions. Theoretically, it should be more toxic than propylene. Work on the polymethylenes was contemplated, but their preparation in a pure form was beyond the resources of the department. One of them, cyclopropane, has since been introduced into practice. Propylene has similar properties to it, but it will, I think,

be found to be safer and more pliable in administration. It can be given with an excess of oxygen, and a luxur supply of oxygen is a desideratum in anaesthesia. Thirteen minutes after commencing the inhalation of 12% propylene with 32% oxygen I am reported as having complained of a slight feeling of oxygen want.

The most serious objection to a mixture of propylene and oxygen for amateur administration is its inflammability. The addition of a small amount of a chloro-derivative such as chloroform, or, perhaps better, methylene dichloride, which, notwithstanding statements to the contrary, is less toxic when pure than is chloroform, might counteract this fault. Such a mixture could easily be put up in small bombs of definite capacity, similar to those used for CO₂, which could be released into a large rubber bag containing a prescribed volume of oxygen mixture to give the concentration of anaesthetic which may have been found to be safe and effective for the conditions required. A mouth-piece is much preferable to a face-piece, and the uncomfortable nasal clips used in my experiments might be replaced by cotton-wool plugs in the nares. The required apparatus should be easily portable, especially if small oxygen bombs could be supplied. To anyone sufficiently interested to investigate these possibilities I offer myself as an experimental animal.—I am, etc.,

Burley-in-Wharfedale Yorks

C. R. MARSHALL.

Primitive Midwifery

SIR,—I think this may prove of interest. It is an extract from a letter written to me a few years ago by Dr. Marian Smythe, then in charge of the Elizabeth Newman Hospital in Kashmir, in answer to questions I had written to her.

"I had an interesting experience last year. I was in a village and was called out to a house where a woman was in labour, a primipara, fully dilated, with rather funnel-shaped pelvis, membranes ruptured. Foetal heart very irregular and rapid and very hard pains. As there was no sign of advancing—head wedged firmly in the pelvis with a narrow outlet—I said, 'Only forceps will get that out,' and sent to our camp for them and chloroform, meanwhile *samjaing* (lecturing) the relations. They were very *jungly* and implored me

to wait and brought in a village *dai* (hereditary midwife). I have tried to draw a rough picture of what happened. The kneeling one is putting her finger down the patient's throat to produce vomiting. The squatting one is, I suppose, pulling the outlet open, though she wouldn't tell me or let me look, and was very shocked by my questions and said it was '*Sharm hungkat*' (shame). The seated lady is clasping the abdomen with all her strength. Between them they produced the child in ten minutes, stillborn, before my forceps arrived.

"I suppose they have been doing this since the days of Abraham (viz., Genesis xxx. 3; Exodus i. 16). This is the only time I have seen this, and my questions here elicit nothing of the sort from city *dais*, so I gather it is only in villages they do it now. This was in one of the Sindh valley villages up the mountain near Wozil Bridge, pretty remote from civilization."

The indigenous midwives are such by caste and have picked up the knowledge they possess from their mothers. They are very reticent about their practices, but do craniotomies with a sharpened stick and extract with a piece of string, and they rely largely on change of posture during labour and the use of salt pushed into the vagina to heal the wounds they have made. To clean their hands before making an examination I have seen them rub them on the floor; in most cases this is of earth beaten down hard.—I am, etc.,

London, N.W.11.

KATHLEEN VAUGHAN

Oral Reactions to Penicillin

SIR,—In reply to the letter by Drs. P. Ellinger and F. Mackenzie Shattock (March 5, p. 411), I regret attributing to them the statement made in my paper (Jan. 29, p. 171) that the oral reaction was largely one of nicotinamide deficiency. I was perhaps misled by the suggestion in their summary that symptoms disappeared after the discontinuance of the drugs and the administration of nicotinic acid.

In the cases I examined no examination of the elimination of nicotinamide derivatives was made. Those patients receiving penicillin tablets containing 6 mg. of nicotinamide received a total of about 60–90 mg. of nicotinamide a day. On the other hand, no cases under treatment with penicillin exhibited clinical manifestations of nicotinamide deficiency, and discoloured tongue following prolonged (4–5 days) treatment with local oral penicillin is common. The explanation for these discoloured tongues suggested by Dr. N. Gohar (Feb. 26, p. 367)—pigmentation due to saprophytic fungi—appears a likely one, and worth further investigation.—I am, etc.,

London, W.C.1.

W. G. CROSS.

Fish Poisoning

SIR,—The annotation in the *Journal* of Feb. 19 (p. 317), concerning poisoning after eating fish from localities in which surplus war material had been dumped, recalls to mind a happening in Egypt during the late war. Food poisoning after eating fish from Lake Timsah, on the Suez Canal, occurred in the Ismailia area. I do not know the symptoms in humans but it was alleged that the fish concerned caused paralysis when fed to cats. It was thought at the time that there was some connexion between the outbreak and the numerous mines and bombs which had been dropped in the canal and lake.—I am, etc.,

Birmingham, 3.

B. R. SANDIFORD.

Hunterian Oration

SIR,—It is a matter of regret that Mr. H. S. Souttar in his recent lecture (*Journal*, March 5, p. 379) saw fit to make certain statements liable to give offence to the countrymen of John Hunter. It is historically inaccurate to state that the Highland army pillaged Glasgow and invaded England in a destroying horde. No army ever entered hostile territory and did less damage. He has evidently become confused with "Butcher Cumberland" and the English army, who established "an all-time-high" for murder, arson, pillage, and destruction. His comparison, too, of Highland barbarity and Afghan civilization is likewise unfortunate. Actually, in the 1741 period the Highlands were enjoying under Macdonald, Mackay and MacIntyre a literary efflorescence unparalleled in Europe. A Hunterian lecturer should be meticulously accurate.—I am, etc.,

Oban.

ATHOLL ROBERTSON.

Tuberculous Meningitis

SIR,—Drs. J. Rubie and A. F. Mohun show again in their excellent article on tuberculous meningitis (Feb. 26, p. 338) how much the success of streptomycin treatment depends on early diagnosis, which, of course, is most difficult in the young child. For him the diagnosis is still very gloomy. Could not the general practitioner and the clinic doctor help by making much wider use of a reliable tuberculin skin test? Professor W. S. Craig (Aug. 21, 1948, p. 374) states that the prodromal stage of (usually) two to three weeks may extend to two months, and that it is "characterized by symptoms which individually appear to have no serious import but collectively reflect considerable and to some extent increasing

physical and emotional debility." When the doctor is consulted at that point and finds no definite physical signs he may well be tempted to prescribe in the first resort a simple tonic or vitamin preparation.

At this stage surely the routine employment of a test such as the Mantoux or the multiple pressure test is very desirable. If it is negative, tuberculous meningitis is a most unlikely diagnosis; if it is positive, further investigations are definitely indicated; and in either case the doctor will have obtained for his records information which will be useful to refer to on later occasions. It is admitted, of course, that the test will very commonly give a negative result in such cases, but is not the chance of very occasionally spotting an early case of tuberculous meningitis, or of other active tuberculous infection, well worth the trouble which this procedure involves?—I am, etc.

Oxford.

W. G. HARDING.

SIR.—Tuberculous meningitis, once a hopeless condition, is now accessible to treatment, as has again been shown by Drs. J. Rubie and A. F. Mohun (Feb. 26, p. 338). However encouraging this is, I would like to point out that most of the articles dealing with the treatment of tuberculous meningitis fail to represent clearly some facts which have an important bearing upon the results.

It is generally agreed that the results are less favourable the younger the children are, especially in the first three years of life. Out of 54 cases (Rubie and Mohun) 18 survived (33%). Table VIII shows that there was only one survivor out of the 17 cases (32%) in the age group under 3 years. 94% of all survivors were older than 3 years.

As a matter of fact, tuberculous meningitis occurs chiefly in early childhood. Out of 163 cases of our observation 94 (57.3%) were under 3 years and 121 (73.7%) were under 5 years. Furthermore, the younger the child is the less characteristic are the symptoms and the more difficult the early diagnosis. Among 76 thoroughly analysed cases there were only 8 (10.5%) which showed the typical clinical course as described in textbooks. The skull is not yet entirely solidified in early childhood, and the intracranial pressure, which is so much responsible for the clinical features, does not rise so much and so early as in older individuals.

The age incidence, therefore, is all-important when assessing the practical results of treatment. This statement does in no way diminish the great achievement, which is already so obvious, in the combat against tuberculous meningitis. It is rather meant to put more accent upon the relation between age and the disease when treated with modern methods, and to show that the less favourably responding young children represent the vast majority of cases.—I am, etc.,

Watford.

S. ENGEL.

Fibrositis

SIR.—Dr. R. O. Adamson (Nov. 27, 1948, p. 956) has stated that in Stockman's book entitled *Rheumatism and Arthritis*, Edinburgh, 1920, there is "ample and clear proof of the reality of fibrositis." I have not read Stockman's book since I was in London eleven years ago, and I am unable to obtain it in this country. I am therefore not in a position to comment on Stockman's work, but I would refer Dr. Adamson to the *American Journal of Pathology* (1946, 22, 121). In discussing the pathology of fibrositis Steiner, Freund, Liechtentritt, and Maun state:

"Hench, declaring the fibrositic nodules as the 'signposts of the disease,' emphasized the disappointing results following biopsy. He found little or no histological abnormality. Other observers (Collins, Slocumb, Buckley) agreed that the structural changes in fibrositic lesions are meagre. The pathological findings in 'fibrositis' as first described by Stockman—namely, numerous fibroblasts, serous or serofibrinous exudate, and thickening of walls of the small blood vessels and nerve sheaths—were considered by Collins as unimportant. Collins emphasized the absence of cellular infiltration as the only important fact in Stockman's investigation."

It would therefore seem that Stockman did not prove the existence of fibrositis, and that later investigations show the existence of this condition to be even more doubtful than was formerly believed.—I am, etc.,

Mr. Hawthorn, Western Australia

JAMES H. YOUNG.

Penicillin in Influenza

SIR.—The present outbreak of influenza, though mild, is completely incapacitating. It is of interest, therefore, that the attack can be cut short by massive doses of penicillin. In a series of twelve cases given a dosage of 750,000 to 1,000,000 units four-hourly, the temperature fell to normal in less than twenty-four hours. A parallel control series showed no such rapid remittance of fever. It is generally considered that the virus is insensitive to penicillin. But with this dosage, and the probable raising of the blood-penicillin level to 7 or 10 units per ml., it is possible that the strain infecting this country at the moment is susceptible to such chemotherapy.

In any case it would appear to be worth extensive trial.—I am, etc.,

London, W.1.

NEVIL LEYTON.

Penicillin and the Infected Hand

SIR.—May I draw the attention of the author of your leading article (Jan. 29, p. 187) to a contribution of mine (*Edinb. med. J.*, 1945, 52, 469) which was one of the first after the original paper by Lady Florey and Dr. Williams? Mr. Barclay, in his paper in the same issue of the *BMJ.* (Jan. 29, p. 175), refers to it, and through his courtesy I was previously aware of the interesting investigation which he was conducting.

In different types of hand infection I contrasted the results of treatment by control methods and by penicillin cream and found no difference whatever. In comparable types these figures were the same as the figures for local penicillin in the series of Lady Florey and Dr. Williams, but much better than their control figures.

In acute suppurative tenosynovitis these writers recorded an important advance by showing that local penicillin treatment could permit of a movable finger, but the limitation of the method was that full movement at the interphalangeal joints was not recovered when pus was present in the tendon sheath. In my own series of cases of tenosynovitis I too obtained some good results with penicillin cream. As penicillin became less scarce, however, the continuous intramuscular drip was used without local penicillin with such success that, out of twenty-five cases full movement was restored in twelve and a very good range in seven. Included in this series were six cases involving the radial and/or ulnar bursae, without a single bad result.

In view of these results it is difficult to understand why, in your leading article, the virtue of local penicillin is so much exaggerated while the value of systemic penicillin is so grudgingly conceded. Systemic penicillin allows the minimum disturbance of the infected part, is the ideal method of treating the more extensive infections, and controls spread in a way not otherwise possible.

In attempting to assess the value of a new remedy such as penicillin it is important to appreciate what were the results prior to it, and it is necessary to assume adequate surgical supervision in all instances, since bad surgery will vitiate any proper comparison. Before the advent of penicillin what types of hand infection did badly no matter how great the degree of surgical skill? Acute suppurative tenosynovitis gave almost uniformly bad results, the outcome being the loss of interphalangeal movement or else amputation of the finger; involvement of the radial or ulnar bursa was a serious condition, carrying the risk of severe loss of function. Acute suppurative arthritis in the great majority of cases gave rise to a stiff joint or else necessitated amputation of the finger. A severe confluent type of lymphangitis due to *Str. haemolyticus*, besides being dangerous to life or causing a long illness, was capable of producing most serious crippling; sulphonamides did not by any means control all infections of this nature. In these three severe types of infection systemic penicillin has proved of immense value and has completely changed the prognosis. I am sorry, however, that Mr. Barclay's series did not include more cases of this severe nature.

As a complete contrast the other common types of hand infection could not be considered deforming or crippling in the absence of severe complications. Perfect recovery was attainable in a high proportion of cases by good surgery alone, and bad results were usually quite needless. Penicillin cannot be expected to produce any great improvement in these, and Mr. Barclay's results are thus understandable. Systemic penicillin, however, has shown its value by some improvement in the time of healing, a satisfactory control of spread of infection, and the avoidance of complications.

Before the use of systemic penicillin there was a rather rare type of spreading or gangrenous infection, usually associated with constitutional factors such as old age, heart disease, and diabetes. In my paper I referred to the fact that these cases invariably did badly with any form of local treatment, but, as Mr. Barclay shows, systemic penicillin, by controlling the original infection quickly, may now be able to prevent this condition.

In any type of infection necrosis is the principal cause of retarded healing and disability, and I noted how it can be traced to such errors as lack of early attention to wounds, too early incision of an area of cellulitis or lymphangitis, prolonged application of hot fomentations, too much reliance on sulphonamides when incisions were called for, and the making of incisions without adequate surgical facilities. These errors are preventable, but, until they can be overcome by adequate methods of education and organization, the results of hand infections are unlikely to show any further spectacular improvement. The great value of systemic penicillin has been established, and further advances in its use will be concerned with new preparations and easier methods of administration.—I am, etc.,

Edinburgh.

J. F. CURR.

Osteitis Fibrosa Disseminata

SIR,—I have read with much interest the paper by Mr. D. J. MacRae carrying the above title (March 5, p. 389). As he quotes freely from papers published by me,^{1,2} in which I drew attention to the association of severe neonatal jaundice and the development of osteitis fibrosa cystica, I should like to comment on that point, and, in the light of present knowledge, to correct the idea that the Rh factor was implicated.

Among the published cases of osteitis fibrosa cystica, in addition to my two cases, one recorded by McCune and Bruch³ and two by Summerfeldt and Brown⁴ had a similar history of severe and prolonged jaundice in the newborn period. At that time the role of iso-immunization in the production of icterus gravis neonatorum, and the importance of the study of the Rh factor in the differentiation of the different types of that condition, were unknown. Recently, in my two cases, the Rh factor has been examined, and in each case the mother has been found to be Rh-positive. They cannot be classed, therefore, as cases of "haemolytic disease of the newborn," although the fact that they suffered from "icterus gravis"—severe jaundice—of unknown aetiology remains.

Mr. MacRae suggests that the bone disorder may be due to disturbance of parathyroid function, and relates that to the neonatal jaundice. It has been established that kernicterus may result from neonatal jaundice of varying aetiology, and the possibility of a resulting lesion of the central nervous system being responsible for the endocrine disturbance leading to the precocious puberty which occurs in some of the patients suffering from osteitis fibrosa cystica was discussed in my paper. All my evidence, however—absence of hypercalcaemia and hypercalcaemia, a positive calcium balance, and a negative rabbit test for the presence of parathormone in the blood—was against implication of the parathyroids in the production of the bone changes—I am, etc.,

Ocular Filariasis

SIR,—The following case is of interest because of its unusual occurrence in this country. On Aug. 20, 1947, a man aged 30 attended Oxford Eye Hospital with a worm moving under the lower bulbar conjunctiva of his right eye. He had been resident in West Africa for nine months prior to returning to U.K. in February, 1946, and within a month of his return he began to have Calabar swellings that caused him very little discomfort. The last of these had been under the skin of the left lower lid, then the nose, then the right side of the face, this last occurring the day before the subconjunctival signs.

On examination, a worm was seen to be moving slowly and snakelike under the lower bulbar conjunctiva of his right eye. During an hour's observation it completely disappeared twice. The patient was only conscious of very slight local irritation. Under 4% cocaine drops, which seemed to have no effect on it during the minute of application, the worm was removed intact through a small incision in the conjunctiva by easing it out over the closed blades of blunt-pointed conjunctival scissors and lifting it away with non-toothed forceps. It made no effort

to go deeper during this procedure, but became very active after removal, in air and in saline. The eosinophilia was 40% of a total W.B.C. of 11,000. No microfilariae were found in the peripheral blood about that time. About seven weeks later another subconjunctival worm appeared, spending most of the day in view. The patient was then in another part of the country, and the worm was not removed. He has subsequently had a course of stibamine glucoside. Calabar swellings are continuing, but are becoming less frequent (one every three or four weeks instead of one or two every week).

The worm was identified by Professor J. J. C. Buckley as an immature male *Loa loa*.

The maximum time that could have elapsed between the first possible infestation and the appearance of Calabar swellings was ten months. Duke-Elder¹ cites one year as the shortest period recorded. According to Connal² the shortest period recorded in Europeans is three months, and four, seven, and nine months were recorded by him.

I should like to make acknowledgment to Professor J. J. C. Buckley, Professor of Helminthology, London School of Hygiene and Tropical Medicine, for his identification of the specimen, and to Mr. Victor Purvis, Oxford Eye Hospital, surgeon in charge of the case.

—I am, etc.,

St. Andrews.

W. G. BRIDGES.

Treatment of Varicose Veins

SIR,—Mr. C. H. Wickham Lawes's temperate and valuable letter (March 5, p. 412) recording his phlebographic studies discloses once more the surgeon's uneasiness of mind about this business of sclerosant injections. And well that it is so—for varicose veins, left alone or with no other treatment than bandage or stocking, have carried no mortality; whereas injection alone, or as ally to ligation, has—and, I assert, will. And who dares counter with the sop that varicose veins may become so harsh an affliction of man's estate on earth as to warrant the risk of death in seeking its relief?

I hope you will permit a personal note. I was at one time exponent and advocate of the sclerosant injection treatment, all the more readily following Sicard, for I had already observed the "sclerosing," thrombosing effect of my injection of quinine into the lower-leg varicose vein of a male patient down with malignant malaria. I even accepted the preposterous claim that the "venitis" provoked by the chemical sclerosant differed from other phlebitis in that the thrombus resulting from this venitis was safely fixed to the vein and the other kind was not. Further, that the clinical proof of success was manifest in a firm, hard thrombus following injection, promising fibrosis of the vein—the fibrous cord, once a vein, being eventually absorbed.

Far too many, and I for one, uncritically saw here a rational, simple, and safe treatment and an instant escape from barbarous guess, slash, and stitch operations for varicose veins, with their seldom successful and always unsightly results. I (not alone) found by biopsies after injection that the thrombus was invaded by mononuclear cells, deriving apparently from the vein endothelium and fixing it to the endothelium, and I (not alone) thought that these mononuclear cells, dubbed fibroblasts, were converting the vein into the desired solid fibrous cord. Later on, after the disappointing and almost constant discovery that when examined six months and more after injection by far the majority of injected, firmly thrombosed veins had recanalized, biopsy studies were again undertaken, as occasion served, over a period of years.

These studies revealed that the invading mononuclear cells from the endothelium were phagocytes in effect, digesting and removing clot. The process was a slow one: in one case I found the thrombus riddled with mononuclear cells and firmly adherent to a sector of the vein's lumen nine months after injection, and in many cases recanalization was proceeding six months after injection. Clearly no follow-up was of value less than nine months after injection; furthermore, the clinical course and the findings of biopsy gave the same results in cases of spontaneous (non-injected) thrombophlebitis of varicose veins. The conclusion was inescapable: that a firm hard thrombosis promised eventual recanalization, not obliteration. On the other hand, I observed (but seldom), following injection of smaller varicose veins, a severe phlebitis, periphlebitis, and cellulitis—acute pain ending rather suddenly after a day or less—in this very unlike the usual injected vein. The affected vein was doughy to palpation, and after twenty-four hours not tender to digital pressure. Biopsy discovered intense inflammatory reaction in the adventitia.

enclosing small areas of extravasated blood—scanty, small round cell infiltration of the vein wall and little or no endothelial cell invasion of clot which lay unattached in the lumen of a vein killed by destruction of its nutrient vessels—a viper venom effect. I could scarce conclude but that successful injection must destroy nutrient vessels, necrose veins, produce an unanchored clot and clinically a soft rather painless thrombophlebitis—a success fraught with danger to the patient.

Fatal accident after injection has been rare, because with injection alone necrosis of the vein occurs only in the smaller superficial veins and that rarely. I is not disputed that injection sometimes has a chain effect—the consequent thrombophlebitis spreading with unexpected speed and violence—and even restarting with new severity after apparent cessation. That ligation and its consequent venous stasis may magnify venously the inflaming, thrombosing effect of injection—nor disputable that should it occur, a deep thrombosed vein of which the necrosed wall cannot send anchoring cells into its contained clot would constitute a lively danger to its carrier. We can all agree with Mr. William Lawes that “we knew beforehand that the blood goes from the superficial to the deep veins, and the position of the main communicating veins has been known for a long time.”

Massive doses of strong sclerosants should be abandoned. With great respect, I suggest to him that should he, as ally to his phlebographic studies, take advantage (as I have done) of the frequent occurrence of varicose veins in both legs of the same patient to perform ligation and injections (retrograde or otherwise) in one leg and ligation only in the other leg (what better control could there be?), he will—I am confident of it—find that his injections of “minimal amounts of minimal strength” have had no effect other than to give extra pain and a longer convalescence. Success will be found to depend only on the number and sites of his “ligations.”

Sclerosant injection is a dangerous ally, or a useless one. It keeps a place in treatment only because of too short a time of follow up, lack of controls, and incomplete knowledge of what it may do. A varicose vein the whole of it, can be extirpated by resection, or avulsion of varying lengths, through incisions one quarter to one third of an inch in length (0.6–0.8 cm) at selected and previously indelibly marked sites along its course. These incisions, if made parallel with the elastic fibres in the skin, gave very little and require no suture. After a thousand varicose vein legs thus treated I can give the assurance that this operation carries no risk to the patient, who can get up and about immediately on recovery from the anaesthetic, it can often be carried out under local analgesia. There is no pain, cosmetic results are excellent, and if the whole vein is extirpated (sometimes difficult to ensure this) there is, of course, no recurrence—I am, etc.

H. M. HANSCHALL

Carcinoma of Cervix

SIR—I have read with interest Mr. W. Sampson Handley's reply (Jan. 22, p. 156) to my letter, but I am afraid his correspondent has misled him into certain inaccuracies which can easily be corrected. First, Kikuyu circumcision is complete not partial as Mr. Sampson Handley states. By this I mean that the whole of the glans penis, including the corona and the sulcus round it, is fully exposed and is fully visible without retracting any tissue. There is no spur of preputial tissue on each side of the fraenum. The fraenum is removed when the operation is performed. The spur of tissue is at the end of the shaft of the penis on the posterior aspect. This spur can give no harbour for the “mixed bacterial flora” which, according to Mr. Sampson Handley (Nov. 22, 1947, p. 841) flourish beneath the prepuce and may cause carcinoma of the cervix in females. I have myself examined and treated several thousand Kikuyu males with venereal disease so I am in a position to know about this matter.

If carcinoma of the cervix is due to the mixed bacterial flora as Mr. Sampson Handley suggests surely it would make no difference if the male was circumcised at puberty (as in the Kikuyu or Fijian) or in infancy (as in Jews). In neither case would mixed bacterial flora be able to flourish beneath the prepuce as they do in the uncircumcised. Mr. Sampson Handley speaks of the complex mixture of circumcised and uncircumcised tribes in East Africa and very boldly states this is not an area where unequivocal evidence on this matter can be obtained. This may be true of the towns but it is quite untrue of this district which is in the centre of the Kikuyu Reserve and far from any town. It is from this district that all my cases of carcinoma of the cervix come.

Except for a handful of Indian traders and European officials and missionaries no race other than the Kikuyu is allowed to live in the Kikuyu Reserve, nor do they—the Kikuyu see to that. I have spent a good many years in this district and I have never known a Kikuyu woman from this district marry a man who was not a Kikuyu. Some of my cases of carcinoma of the cervix have spent all their lives in places where the only adult uncircumcised males for 25 miles (40 km) in any direction are European missionaries—men whose morals are above question.

In conclusion, the difference in the incidence of carcinoma of the cervix in different races must, I think, be put down to some racial factor which we do not as yet fully understand, not to the circumcision rate in the males of the race—I am, etc.

E. MALCOLM CLARK

Spontaneous Amputation of Cervix

SIR—The interesting case of spontaneous amputation of the cervix which Dr. W. Arnott reported in his letter (Jan. 22, p. 157) induces me to recall an identical case described by me and Dr. Zielinski in 1946¹. During a rather prolonged labour in a primigravida aged 36, a plum coloured swollen cervix, attached only by a narrow strip of tissue to the vaginal wall, was delivered before the foetal head. The detached cervix was of a saucer shape 4½ in (11.4 cm) in diameter and 1 in (2.5 cm) in its thickest spot. The external edges corresponding to the line where the detachment occurred, were as thin as paper. The position of the os, 1 in (2.5 cm) in diameter, was eccentric. The rest of the second and third stages of labour and the puerperium were uneventful. Further observation of the patient was not possible owing to her departure from this country.

At the time when this case was described there were 17 cases of spontaneous detachment reported in the literature and also 21 cases of detachment in which some obstetrical operations were performed. De Costa² gives the following statistics which throw some light on the causation—namely in 100% there was head presentation, in 100% premature rupture of the membranes occurred, in 100% the labours were prolonged, 88% occurred in primiparae, in 58% the age was over 36. The fact that in the majority of cases with interference the Champetier de Ribes bag was used indicates that the cervix did not dilate. It may be concluded that the expansion and thinning of the lower uterine segment above the cervix, undilated for some organic reason, leads to the detachment of the cervix—I am, etc.,

Transmission of T. Duttoni

SIR—I was very interested to read Dr. R. B. Heisch's paper (Jan. 1, p. 17) on “The Human Louse in Transmission of *T. duttoni* in Nature.” When I was stationed at Mazabuka, Northern Rhodesia in 1938 seven cases of relapsing fever occurred in the local prison, of these three were among detained persons who lived in a building infested with *O. moubata*. The remaining four were convicted prisoners who were confined in the gaol, a building made of burnt brick with inside walls lime washed and painted with tar on the lower portion, the floor was cement and the roof corrugated iron. Repeated search failed to reveal any ticks, but the prisoners' blankets were found to be infested with lice. I have no record of how long the prisoners had been in gaol before becoming ill but I remember it was clear at the time that the relapsing fever in each case must have been contracted while a prisoner and not while detained. As far as I can remember, the blankets and the clothing of all occupants of the gaol were disinfected and no further cases of relapsing fever occurred.

In my 1938 Annual Report for Mazabuka I commented “the possibility has to be borne in mind that this disease among the prisoners is louse-borne.” The Director of Medical Services, Northern Rhodesia in his Annual Report¹ for 1938 for the Territory, mentioned the Mazabuka findings and said, referring to relapsing fever “The first suggestion so far as I am aware, that this disease in Northern Rhodesia is ever

other than tick-borne, occurs in the 1938 report by the Medical Officer, Mazabuka."

In view of Dr. Heisch's report on the finding of *T. duttoni* in lice from Africans ill with relapsing fever I thought it would be of interest to place on record my experience, as it would appear that transmission by lice of Central African tick-borne relapsing fever is not only possible but does in fact occur in nature.—I am, etc.,

Broken Hill, Northern Rhodesia.

III Children Remember

SIR,—Ann is now convalescent, an intelligent and charming little person of 11 years. But when, soon after admission to hospital with subacute rheumatism, she developed a fulminant attack of chorea we had little time or inclination to notice how pretty she was, for we wondered if ever we were going to calm her restless, never-ending involuntary movements. They were distressing to watch, the more so because overnight she had lost her speech completely. From time to time her jerky movements were punctuated by a weird and piercing scream—surely, we thought, something purely reflex and unconscious.

Not for twenty-nine weary and worrying days did she recover sufficiently to regain her speech. At first she could utter only short, simple phrases, but four days later she was speaking normally again. We had thought that she was too far gone at the height of the illness to be conscious of what was going on around her, but we were wrong. During the whole twenty-nine days when she could not speak she remembers and can recount vividly a host of trivial incidents. One day her daddy and her aunt came to visit her. She recalls her aunt slipping away quietly and saying to her father, "I'd better go out first in case we upset her." Once, hearing her father's voice whispering outside the nearby door of the ward, she managed to point to the door and so make the nurse bring him in.

She has vivid recollections of the visits of the various doctors; she used to get upset because she imagined that they regarded her as a stubborn little girl when she did not answer them. She remembers the actual word "chorea" being mentioned. From something her father let fall in her hearing she realized that he thought (as indeed he did at one period) that she would not get better.

The screaming noises were her attempts to tell us something. For example, on Christmas Day she had no presents. She realized that this was to prevent her getting excited (in actual fact we never thought that she was "with us" sufficiently to appreciate the significance of the day), but she was none the less disappointed, and she says that she tried to tell the nurses that she wanted to go home by pointing to the window and trying to utter the word "home." They, alas, saw only a purposeless movement and heard a shrill cry. She remembers crying over her aches, which (she tells us) were brought on by sudden noises and also by the light over her bed. Added to her other troubles, her joints were very painful, and although the nurses hurt her when they moved her she could find no way to tell them.

Now, however, Ann is convalescent, and can tell us these things. This she does with an engaging grin. To us it is a salutary lesson that patients who are desperately ill may take in far more than the ordinary observer suspects.—I am, etc.,

Liverpool Royal Infirmary.

J. STUART JONES.

Aftercare of the Hospital Patient

SIR,—I was naturally interested in the annotation in the *Journal* of Feb. 16 (p. 358). The Cardiff scheme, using health visitors, dated from 1944; it began with diabetes and afterwards was extended to peptic cases. As a municipal scheme it was convenient to start it with ex-municipal-hospital patients, but for diabetes the advantages are now available to patients from all hospitals in the area, and some are even referred by general practitioners. The work of the health visitors is supervised by a consultant physician from the diabetic clinic of the Cardiff United Hospitals, who is paid on a sessional basis by the local health authority.

On the suggestion of the Cardiff paediatrician, Dr. A. G. Watkins, the benefit of the follow-up is now to be conferred upon infants and children. Two health visitors, with special

aptitude and liking for the work, will visit the children's wards and learn about difficult cases which have to be followed up afterwards. These two might either themselves follow up or explain the details to the district health visitors, who in turn will follow up. It is hoped that the introduction of this system will prevent the readmission to hospital of many cases especially difficult infant feeding cases.

Only the "hold-up" over the consultant service generally has prevented the aftercare work in Cardiff through health visitors already including cardiac patients and asthmatic patients as well as the categories mentioned.

There is no conflict between health visitors and hospital almoners in Cardiff, but on principle I would take leave to doubt the ability of almoners anywhere to undertake some important aspects of the work. In dealing with diabetes the health visitor gives considerable technical instruction—e.g., as to use of syringes, testing urine, and diet. It is difficult to believe that anyone such as an almoner without the basic nursing training possessed by a health visitor could undertake this work, and if she cannot it is necessary to have her duplicate the visit of the health visitor just for "social case-work"?

In this age of clichés we are faced with yet another before which we are expected to fall back in awe. There is a mysterious "something" about this cliché which some use to assert a kind of superiority of the social-science diplomat over the better-experienced and far-longer-trained health visitor.—I am, etc.,

Cardiff.

J. GREENWOOD WILSON.

Milk Standards

SIR,—Recent parliamentary debates and letters to the medical press have again drawn attention to the dangers still existing from the spread of bovine tuberculosis by milk. As far as I know, the general attitude of the medical profession, and on forcibly voiced by the British Medical Association, is that pasteurization provides sufficient safeguard to milk supplies. This is undoubtedly true as far as it goes, but it must be acknowledged that pasteurization is only a means by which risks to health resulting from earlier errors in production can be minimized. It has always seemed to me undesirable that the public should be expected to drink dead or devitalize microbes of any sort. In emergency, many have drunk previously contaminated water sterilized by boiling, but this is not a practice to be advocated except at such times.

There seems little doubt that the advocacy of pasteurization and its actual practice have seriously retarded fundamental improvements in the standards of milk production in this country, because the tendency has been to produce large quantities of indifferent quality subsequently rendered safe by pasteurization. It is disquieting that only 13.9% of the milk producing cattle in this country are known to be tuberculosis free; happily, the number is increasing. Somehow the idea of tuberculin testing of herds has not caught on in Great Britain to the extent it has in the United States of America where the possession of untested milking animals is unthinkable. In pre-war days there was a feeling that tuberculin tested cattle only belonged to cranks or gentlemen farmers whatever the latter term means. Most farmers, naturally, were not interested in anything which raised their costs, with the public only interested in cheap food. Little attempt has been made to educate public opinion in the need for considering the quality of milk available and that it must be sold at an economic price. The mass of the population in Great Britain is, of course, so urban-minded that for many milk is something from a bottle, and whether it has a good fat content or is contaminated does not worry them, whereas in the United States, traditionally, the population is much better informed about such matters. The efforts by the Ministry of Agriculture to increase the number of licensed tuberculin-tested cattle and attested herds in Great Britain is to be welcomed, but I doubt whether this commendable effort will be as successful as it might be until the oft-quoted statement, "Of course, you doctors advocate pasteurization," can be denounced forcibly by positive action on the part of the British Medical Association to stimulate an increase in the number of tested animals.

In the advocacy of positive health—the modern theme dominating, or which should dominate, current medical

practice—much can be done to convince milk producers of the need for improvements in the technique. It is not enough to know that cows are tuberculin-tested and that milking stands are surrounded by a four-foot dado of cement, when udder cloths are roughly washed in water which may be little better than dilute liquid manure. In this matter of udder cleaning undue reliance is still placed on antiseptics, which may be useful provided they have time to act; how much better it would be if a point like this were more widely known.

In many matters finance still has to govern policy. If money be available much can be done to improve dairies and other buildings, many of which are a century or more old, which they look. They look old, and they have not been replaced because for the past seventy-odd years all farming—and this includes the production of dairy products—has been of no particular interest to the community as a whole; whether the present signs of a reawakening interest will be more than temporary time will show. Unrestricted imports of food damaged farming permanently in the past and may do so again. Whether present endeavours to re-establish British agriculture will be successful on a long-term basis and automatically raise the standard of milk production would seem to depend upon the farming community realizing that popular interest in them is deep-seated and not simply one of expediency. Memories of the past are long. Until all dairy cattle can be tested and culled it is obvious that during the transitional period pasteurization must continue. This should be looked upon purely as a temporary measure, to be discarded as rapidly as possible—I am, etc.,

London, W.1.

W. R. THROWER.

Temperature Recording

SIR.—Further to the very interesting article by Professor Alan Moncrieff and Dr. B. J. Hussey (Dec. 4, 1948, p. 972) and the ensuing correspondence, may I be allowed to add a few remarks which may be considered of practical interest?

My remarks concern that most awkward age for temperature recording—namely, from 1–3 years. The child is then too young to be trusted with a thermometer under the tongue and too old to tolerate a rectal thermometer with nonchalance (I have ignored the axillary and groin methods as being inaccurate and time-consuming). This age period incidentally provides the bulk of child patients in a busy general practice, and it is from time-saving considerations only, without, I maintain, sacrificing accuracy, that I put forward this method of temperature recording, which I have been using for the last few months.

The technique is quite simple. One directs the bulb of the thermometer gently along the floor of the right cheek between the gum margin and the cheek until the bulb can be felt protruding by a finger laid gently over the outer side of the cheek. The thermometer is steadied with the right hand, the bulb pressed into the buccal sulcus, and the mercury can be watched as it rises. The points I wish to make are as follows:

(1) If the child is feverish the mercury can be seen to rise within a few seconds only to its maximum. After all, one does not necessarily need to know the exact temperature to a tenth of a degree or so, but the state of illness of the child. The rapidity of the rise of the mercury gives this indication, together with one's other simultaneous clinical findings, such as the pulse rate and general appearance of the child.

(2) The child rarely, if ever, objects to this method. It never seems to taste the antiseptic in which the instrument is carried, as it does in the sublingual method. Any objection can usually be dispelled by telling the child to "smoke a cigarette like daddy does."

(3) The mouth can be gently closed by one's free left hand whilst the temperature is being taken.

(4) I have used this method now in several hundred cases and have never run the slightest risk of the instrument being bitten.

Of course this method would be unsuitable for the more leisurely atmosphere of a hospital ward, but I have found it an invaluable time-saver in the present measles epidemic in this town (when one is asked casually to see sometimes five or six children in one house), without in the least, I feel, leaving one with the impression that one's work has been inaccurate and that the patient has suffered thereby.—I am, etc.,

Southampton

S. R. SAUNDERS.

Obituary

JOHN MCGIBBON, M.B., F.R.C.P.Ed., F.R.C.O.G.

Professor John McGibbon, who died suddenly at Crieff on March 5, had been professor of obstetrics at the University of Witwatersrand before being appointed to the chair of midwifery at St. Andrews University.

John McGibbon was born in Edinburgh in 1876, and graduated M.B., Ch.B. at Edinburgh University in 1898. It was intended that he should assist his father in carrying on a large general practice in the city with a view to taking over the practice at a later date. This intention was not fulfilled, for, after a period as house-surgeon at the Royal Maternity Hospital of Edinburgh, McGibbon became interested in midwifery and gynaecology, and when he later received a gynaecological and obstetrical appointment in the city he decided to give up general practice and devote himself entirely to this specialty. He was appointed to the chair of obstetrics at the University of Witwatersrand, in Johannesburg, in 1922, and in 1928 was recalled to Scotland to occupy the chair of midwifery at St. Andrews University. At the same time he became obstetrician and gynaecologist to Dundee Royal Infirmary. In the following year he became one of the foundation fellows of what was then the British College of Obstetricians and Gynaecologists. Unfortunately his tenure of the chair at St. Andrews was interrupted by ill-health, and he was unable to devote as much of his abundant energy to its duties as he would have liked. He did recover sufficiently, however, to carry on the duties of the chair for another two years after his formal retirement in 1938, so that arrangements could be made to appoint his successor.

Professor McGibbon was a most popular examiner both with colleagues and students and seemed thoroughly to enjoy taking part in examinations. After he had acted as an examiner at practically all the Scottish universities, and on finally retiring from the chair at St. Andrews, he applied for appointment as an examiner to the University of London and carried out this duty for a number of years. For the last few years Professor McGibbon had lived in Crieff, and he was not well enough to take part in medical activities or mix with his colleagues and friends in Edinburgh and Dundee.

He is survived by his widow, a daughter, and a son, who is one of the radiologists at the Royal Infirmary, Edinburgh. To all his family the sympathy of many friends and colleagues will be extended.

ETHEL VAUGHAN-SAWYER, M.D.

Dr. Ethel Vaughan-Sawyer, who died at Mount Vernon Hospital on March 9, was born in 1868 and was the daughter of Cedric Vaughan, J.P., of Millom, Cumberland. After early education at Lausanne and University College, London, she entered the Royal Free Hospital in 1891. She won many prizes as a student, and graduated M.B., B.S. in 1896, preceding M.D. two years later. After working at Camberwell Infirmary as assistant medical officer, Dr. Vaughan was appointed pathologist to the Royal Free Hospital and worked there from 1899.

Mrs. Scharlieb, afterwards Dame Mary, was at that time senior gynaecological physician to the Royal Free Hospital and the first woman to hold such a position on the staff of a London teaching hospital. In 1902 Ethel Vaughan was appointed assistant physician for diseases of women and assistant obstetrician. When Mrs. Scharlieb retired in 1908 Miss Vaughan succeeded her and was also lecturer in gynaecology in the University of London until 1929, when she was made consulting gynaecologist to the Royal Free Hospital. On her marriage to Captain Henry Sawyer, of the Indian Army, Ethel Vaughan took the name of Vaughan-Sawyer. Her married life was extremely happy and she never ceased to mourn her husband's death in action in 1914. There was one daughter of the marriage, but unfortunately she died. An attack of glaucoma compelled Mrs. Vaughan-Sawyer's retirement from the hospital and from active surgery in 1928, and in spite of

remissions her eyesight gradually failed until she was completely blind for the last ten years of her life. She taught herself Braille and continued to live in her house in Harley Street until the last two years, which she spent in a home where she was happy and received every care.

Many generations of students of the Royal Free Hospital will remember Mrs. Vaughan-Sawyer. She was a vivid personality, an excellent diagnostician, and a meticulously careful surgeon. She was particularly successful in the performance of Wertheim's hysterectomy for cancer of the cervix. In those days "follow-up" clinics for cancer patients were relatively rare, but her cases were seen at regular intervals after operation. Mrs. Vaughan-Sawyer's kindness and generosity were unbounded, both to her patients and to her old students and residents whenever they needed help of any kind. Her great success both in hospital and private practice, apart from her surgical skill, was due to the great interest she took in the lives of her patients. "Tottie," as she was affectionately called, loved the pleasures of life—good food, good wine, an evening playing bridge, and, though often casually and always unfashionably dressed, she delighted in seeing people smartly and expensively attired. She was an entertaining conversationalist, with a characteristic chuckle.

In spite of her family griefs and her progressive ill-health, Dr. Vaughan-Sawyer still managed to enjoy the company of her many friends. Even within two weeks of her death from a recurrence of malignant disease, and while completely paraplegic, she was able to say with almost her old sparkle: "You know, I've had a wonderful life, and am still thrilled when I think about it." It is this aspect of her personality that will live longest in the memory of those who admired her so much.

A. W. WAKEFIELD, M.D.

Dr. Arthur Wakefield, who died at his home in Keswick on Feb. 23 at the age of 72, had led a life of stirring adventure and strenuous endeavour. He was born in Kendal in 1876, a son of the late William Wakefield, of the Wakefield and Crewdson banking house. He was educated at Sedbergh School and at Trinity College. At Cambridge he got a "half-blue" for cycling, boxed as a middleweight against Oxford, and rowed "head of the river." He served as a trooper throughout the South African War. In 1904, when he captained the London Hospital rugby team, he took the L.R.C.P. and M.R.C.S., and he won the United Hospitals heavyweight boxing championship. In that year, too, he put up a mountain-climbing record, ascending Sca Fell Pike, Helvellyn, Skiddaw, and most of the highest intervening peaks, in a little over 22 hours—a record which was not beaten until 1920. In 1905 he graduated M.B., B.C., proceeding M.D. in 1909.

From 1908 to 1914 Dr. Wakefield was medical officer to the Royal National Mission to Deep Sea Fishermen in Labrador and Newfoundland, working with the famous "Grenfell of Labrador." He was organizer and captain of the Labrador Unit of the Legion of Frontiersmen, and in the 1914-18 war he served in the Newfoundland Regiment, R.A.M.C., and was mentioned in dispatches. After the war there followed a spell as surgeon to the Canadian Pacific Railway. Finally, in 1923, he settled as a general practitioner in Keswick with his wife, who was president of the National Council of Women. He was, among many other things, medical officer of the Keswick Home during the recent war.

As a mountaineer that Dr. Wakefield will be best remembered. In common with many members of Everest expeditions, he learnt his climbing in Lakeland, and was initiated by the pioneer brothers, George and Ashley Abraham, of Keswick. With his outstanding rock-climbing ability, great physical strength, medical knowledge, good comradeship, courage, and dogged persistence, he was a most useful member of the 1922 Everest Expedition, when Finch and Geoffrey Bruce reached a height of 27,300 ft. and blazed the trail followed by later parties. He was a member of the Alpine Club, and in 1923-5 president of the Fell and Rock Climbing Club. Dr. Wakefield, although a man of great charm and friendliness, was a severe disciplinarian, deeply religious, and a strict sabbatarian. On one occasion the Abraham brothers induced him to join them one Sunday on an early and difficult ascent of the Devil's Kitchen in Wales. This he enjoyed vastly, but with some mis-

givings apparently, for when he said good night he remarked, "I am going to make my peace with my Maker, but I somehow feel that, under such temptation, He will not be deeply offended." Although many of his contemporaries have gone ahead, many still survive who have the happiest memories of his kindly and helpful friendship, his warm good nature, and his splendid example.

Dr. J. Macdonald writes: Dr. Wakefield was widely known, and was held in respect and esteem by all who knew him. He was always ready to help and always giving of his best, sparing no effort. "No matter how strait the gate, how charged with punishment the scroll," he would go on where his duty lay. His unfailing comradeship endeared him as a friend, and his great courage and determination commanded respect. He was an active member of the B.M.A., being at one time chairman of the local branch and in 1934-5 president of the Border Counties Branch. He was a man of wide interests and extensive experience. Among local and other activities he was at one time president of the British Legion. Unfortunately his later years were marred by a crippling arthritis, but his magnificent spirit remained unimpaired. Undaunted by failing health, he pursued his course to the last, and died in the midst of his activities. Sincere sympathy is extended to his widow, two sons, and daughter.

Dr. GEORGE ALEXANDER DICKSON, West Lothian's oldest physician, died on Feb. 15, at the age of 77, after almost fifty years in practice in South Queensferry. Dr. Dickson graduated M.B., C.M. at Edinburgh University in 1894, and continued his studies in Vienna. He held resident posts in the Edinburgh City Hospital and the Rosslynlee Mental Hospital. After several assistantships he settled in South Queensferry, where he remained in active practice till only a few weeks before his death. He was a loyal and active member of the B.M.A., and was chairman of the Lothians Division from 1923 to 1925. His sound judgment and experience were valued by his colleagues at all the medical meetings he attended. He was a justice of the peace for the county of West Lothian, and in 1946 he was given the freedom of the Royal Burgh of South Queensferry in recognition of his public services. On the occasion of his jubilee in medicine, in 1944, he was presented with a testimonial and a silver salver from his colleagues. Dr. Dickson was highly respected by patients, fellow practitioners, and all who knew him for his kindly, genial disposition and his constant unselfishness and devotion to duty. To those who knew him more intimately he was a staunch friend, and he will be greatly missed in West Lothian. His wife died twelve years ago. He leaves a son and daughter, the latter a member of the medical profession, and to both of them the sympathy of all his colleagues will be extended.—A.S.

Medico-Legal

A HUSBAND'S SULKS

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A recent unusual case on cruelty caused the Court of Appeal some trouble.¹ From the very early stages of an otherwise happy marriage a wife found that her husband was subject from time to time to fits of depression. He would remain morose, sullen, and silent, and would not speak to her sometimes for as long as ten days. This caused her distress and affected her health. The husband knew quite well that his attitude towards her in these moods had a bad effect, and the couple tried to co-operate to cure him, but in vain. At length she told him that unless his manner towards her improved there would have to be a separation. He agreed that he must try to do better, and for the rest of his leave from Germany he behaved very well, and the couple had one of their happiest times since marriage.

His next leave, six months later, started well but quickly deteriorated, and for the latter part of it he ignored her completely, even in the presence of other people. The judge found her story true, held that the facts amounted to cruelty, and granted her a divorce. The husband appealed to the Court of Appeal, which was constituted with the president of the Divorce

trying to know how
 as well as could be
 and to come
 we are looking
 again

'everything seems to go wrong . . .'

How often you hear it in your surgery! People today, harassed and run down, find themselves unable to contend with all the small irritations and minor mishaps of life.

Livogen is invaluable in all cases of nervous depression, reduced vitality and general debility. It restores vitality rationally, by supplementing the normal resources of the body. It is a balanced composition of liquid extract of liver B.P., extract of yeast, vitamin B₁ and nicotinic acid. Bottles of 4 and 16 fluid ounces are available as well as bottles of 80 fluid ounces for dispensing. Literature is available to medical men on request.

AT THE FIRST GASP

Clinical experience has amply confirmed original reports on the value of 'Neo-Epinine' in the treatment of bronchial asthma. Equal to adrenaline and superior to ephedrine in anti-asthmatic activity, it is relatively free from the undesirable side-effects of both these drugs. 'Neo-Epinine' is administered simply, either sublingually or by oral inhalation, thereby avoiding the necessity for injection. Issued for sublingual administration as compressed products each containing 20 mgm., in bottles of 25 and 100; and as 1 per cent Spray Solution in bottles of 10 c.c.

'NEO-EPININE'

ISOPROPYL^{nor}ADRENALINE SULPHATE

BURROUGHS WELLCOME & CO. (The Wellcome Foundation Ltd.) LONDON

SPARKLING CLEANLINESS

Radiographers know that they are assured of exceptional latitude, sparkling cleanliness and excellent contrast when they use Ensign STANDARD X-ray film. The difficulties of chest radiography are manifold. Geometrical distortion by the size of the tube focus, physiological movement and grain of the intensifying screen make the use of Ensign Standard essential. Standard Exposure times can be varied without impairing the high quality of the finished radiograph. Ensign STANDARD is a film of normal speed that will give you the finest possible definition even when dark room conditions are not too favourable.

SKIN AFFECTIONS

AND NUTRITION

The condition of the skin is known to be closely connected with the state of nutrition; for example, skin affections accompany certain vitamin deficiency diseases. An adequate intake of B vitamins is regarded as essential for the maintenance of a healthy skin.

In the treatment of skin complaints associated with a vitamin B complex deficiency, many physicians prefer to administer the vitamins in a natural form, rather than as synthetic vitamin supplements. For this reason Marmite is frequently prescribed; it contains not only riboflavin (1.5 mg. per oz.) and nicotinic acid (16.5 mg. per oz.), but also pyridoxin, pantothenic acid, choline, biotin and folic acid.

Literature on application

Court, Lord Merriman, at its head, and Mr. Justice Pearce, another divorce judge, as one of its members. The third member was Lord Justice Singleton, who disclaims wide experience of divorce matters.

Findings on Appeal

The president said that the trial judge had fully appreciated the necessity for the two essential elements in a charge of cruelty: something that could be called misconduct by the husband coupled with danger, actual or apprehended, to the mental health of the wife. There was abundant evidence to enable the judge to come to the conclusion that the cumulative effect of the husband's conduct was having a serious effect on the wife's nervous and emotional stability. Sulking was not a new ingredient in cruelty, said the president, although no case turning directly on it seemed to have been reported. More than once he had in the course of trying a divorce petition committed himself to the statement that he could imagine no course of conduct more calculated to be destructive of married life than persistent and deliberate sulking. To "send a wife to Coventry" for ten days on end certainly amounted to cruelty, and the suggestion that the husband's action was involuntary was sheer rubbish. When he was pulled up by the wife or her mother he would behave better for a few days. He was not unable to control his temperament, and many of these incidents were brought about by resistance of the wife to the imposition of his will on hers. He had caused her two miscarriages by bullying her by the threat of sulks into going to church when she did not feel well enough. The president therefore found that she should have her divorce.

Mr. Justice Pearce agreed. He had no doubt that the husband's conduct amounted to cruelty in law, and thought the trial judge had taken the fullest advantage of seeing and hearing the witnesses. Even assuming that the husband had no intention of being cruel, his intentional acts had amounted in the view of the trial judge to cruelty. It would be unfortunate if the court were to refuse its protection on the ground that the injury to the wife's health was caused only by the subtle weapon of sulking.

Lord Justice Singleton, on the other hand, saw no evidence that the husband was either tyrannical or domineering. He was not satisfied that there was a deliberate course of conduct of a kind to cause reasonable apprehension of danger to health. He thought there must be something more than moods, and that the husband, though inconsiderate at times, had not been guilty of cruelty in law as his lordship understood the meaning of the word. There were faults on both sides, and he thought she could have done more; they were both difficult people, and he did not think that the legislature, in the word "cruelty," had intended to include what had been proved in this case. The appeal was, however, decided by the view of the majority.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on Feb. 26 the following degrees were conferred:

D.M.—Mr. A. Partridge, A. P. Meiklejohn, G. Gordon, *J. A. L. Leeming.
B.M.—*V. J. E. Davies.

*In absence.

UNIVERSITY OF CAMBRIDGE

Dr. G. R. E. Naylor has been reappointed University Demonstrator in Pathology for five years from Oct. 1.

The *Cambridge University Reporter* dated March 9, 1949, contains a report of the Faculty Board of Medicine on the regulations for degrees in medicine and surgery. The Board recommends that the regulations (*Ordnances*, p. 374) be rescinded and replaced by the regulations set out in the schedule to its report, published in the same issue of the *Reporter*.

UNIVERSITY OF ABERDEEN

William Malcolm Millar, M.D., lecturer in mental health in the University, has been appointed to the Chair of Mental Health in succession to Professor D. R. MacCalman, now Nuffield Professor of Psychiatry in the University of Leeds.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A meeting of the Council of the College was held on March 10, with Lord Webb-Johnson, President, in the chair.

Hunterian Professorships were awarded to Professor C. F. M. Saint (South Africa) and Professor Robert I. Harris (Toronto).

Professor W. E. Gye was elected an emeritus professor of the College as from the date of his retirement from the Directorship of the Imperial Cancer Research Fund.

A Leverhulme Scholarship was awarded to Mr. W. J. Dempster, of the British Postgraduate Medical School.

Mr. L. E. C. Norbury was reappointed as the representative of the College on the Council of Queen's Institute of District Nursing.

Diplomas in Public Health were granted jointly with the Royal College of Physicians of London to P. L. Karney and D. F. van Zwanenberg.

The following hospitals were recognized in respect of the Resident Surgical post required of candidates for the Final Fellowship Examination: R.A.F. Hospital, Ely, 1st and 2nd House Surgeons (General); 1st and 2nd House Surgeons (Orthopaedic); R.A.F. Hospital, Halton, 1st and 2nd House Surgeons (General), 1st and 2nd House Surgeons (Orthopaedic); Warwick Hospital, Registrar to Ear, Nose, and Throat Department.

CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examination, have been admitted L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P.&S.Glas.:

Abd-El-Rahman Azzam, Elspeth V. Beveridge, Mahala M. Beveridge, A. Carlos, Elizabeth Carwardine, J. C. Cassaglia, S. H. Curry, S. B. Davies, I. M. Downie, K. A. H. Fermie, W. O. C. FitzPatrick, R. M. Gaze, J. Govan, J. G. Hart, Mary M. Hay, Lysbeth R. Hurwich, Margaret J. G. Jamieson, J. H. Kennedy, J. J. O'B. Lavery, J. Leonard, D. W. Lyon, G. J. McCann, Sushil Mallick, J. C. Marshall, H. P. P. Morris, J. S. Nelson, J. Ryan, S. Schlifka, J. G. Sheehy, I. Tandatnick, F. Whyte, H. N. R. Wilson, N. W. Wilson, M. Wotherspoon, J. C. Wright.

Medical Notes in Parliament

NATIONAL HEALTH SERVICE

Consultants and Specialists Awards Committee

Sir HUGH LUCAS-TOOTH on Feb. 28 asked the Minister of Health what remuneration he had in mind for the chairman and members of the National Awards Committee set up on the recommendation of the Spens Report on the remuneration of consultants and specialists.

Mr. BEVAN said that the chairman of the Awards Committee was being paid a salary of 3,000 guineas for the first year, 2,500 guineas for the second, and 2,000 guineas for the third. Those members of the committee who were retired received a fee of 7 guineas for each day given to the work of the committee.

Foreigners and Temporary Residents

Colonel STODDART-SCOTT inquired on March 10 whether it had been decided upon what principles doctors in the National Health Service were to be paid for the treatment of temporary residents, visitors, holidaymakers, foreigners, and patients not on the doctor's list.

Mr. BEVAN replied that he was still discussing with the profession the principles on which such payments should be made in future. The total amount of these payments depended on the number of persons involved and was a charge on the central pool for the remuneration of general medical practitioners. He had agreed with the profession that payment in respect of the period July 5 to Dec. 31, 1948, should broadly be on the same basis as under the National Health Insurance arrangements.

Answering a further question, Mr. Bevan said these payments in respect of the period July 5 to Dec. 31, 1948, would be made on March 31. Payments were necessarily made in arrears and payment in respect of the period Jan. 1 to March 31 this year would be made on June 30.

Diphtheria Immunization

In 1947 approximately 478,000 children under 5 and 111,000 from 5 to 14 received inoculations against diphtheria under local authority arrangements in England and Wales.

Returns from authorities in England and Wales for 1947 showed that 1,287 cases of diphtheria and 16 deaths occurred among immunized children, as compared with 2,654 cases and 182 deaths among children who were not immunized.

Petrol for Doctors.—Mr. NIALL MACPHERSON on March 3 asked the Minister of Fuel and Power the functions of British Medical Association liaison officers in relation to his department, and suggested that the applications of country doctors for more petrol were being refused. Mr. ROBENS replied that the liaison officers appointed by

the British Medical Association were available for consultation by the regional petroleum officer on any matter affecting an application by a doctor for an allowance of petrol. Doctors themselves could also ask the medical liaison officer to support their application. The appointments were unpaid and no cost fell on the Treasury. Regional petroleum officers had standing instructions to allow doctors sufficient petrol to meet their essential requirements. Mr. Robens was not aware that reasonable applications were being refused, but promised to review any cases brought to his notice by Mr. Macpherson. The regional petroleum officer had the advice of the medical liaison officer nominated by the British Medical Association. The standing instruction to regional petroleum officers was not to set any limit to the amount of petrol a doctor required in the legitimate work of looking after his patients. Mr. Robens added that a medical liaison officer of the standing appointed by the B.M.A. would know something of doctors' requirements and be a good adviser.

Doctors Redistributed.—Mr. BEVAN said on March 3, in answer to Mr. KEENAN, that the total number of general practitioners on the medical list at July 5, 1948, was 18,165; 661 other practitioners had been admitted since then and approximately the same number had left for a variety of reasons. He had no information on the average salaries earned by doctors in that period. Certain payments were made to doctors outside the National Health Service Act. More general practitioners were taking part in the scheme than the Government had estimated at the beginning. There was a surplus of doctors in some places, and as they redistributed themselves there ought to be adequate doctors for all.

EPIDEMIOLOGICAL NOTES

Influenza

There were 259 deaths in the great towns in the week ended March 5, compared with 251 in the previous week. Sunderland 7 (12) and South Shields 5 (6) had fewer deaths than in the preceding week, but there were more deaths in Bradford 11 (3), Leeds 8 (4), and Manchester 23 (16). Deaths in Greater London were about the same 89 (85). In each case the figure in parentheses is that for the preceding week. In certain places—for example, Salford and Leeds—the incidence has been high but the disease has been of a mild type. Nearly all the isolations of virus have been of virus A, which was prevalent on the Continent, but virus B has been isolated from material obtained from two outbreaks in public schools.

Discussion of Table

In England and Wales there were increases in the notifications of measles 553 and acute pneumonia 138. There were decreases in the incidence of scarlet fever 71 and dysentery 25.

The largest increases in the notifications of measles were Devonshire 197, Sussex 181, Staffordshire 138, Warwickshire 112, and Somerset 102; the largest decreases were Southampton 450, Lancashire 218, Yorkshire West Riding 210, and Gloucestershire 135. The only appreciable changes in the local incidence of scarlet fever were decreases in Lancashire 48 and Yorkshire West Riding 25. A small rise in the incidence of acute pneumonia was recorded in most areas of the country.

The decline in the notifications of dysentery was due to decreases in London from 29 to 11 and in Surrey from 12 to 1. Of the 79 cases of dysentery 41 were notified in Lancashire (Liverpool C.B. 24, Manchester C.B. 6, and Oldham C.B. 5).

In Scotland infectious diseases were less prevalent during the week. The only rise in notifications was 39 for measles; the falls included acute primary pneumonia 55, whooping-cough 14, and scarlet fever 12. Notifications of dysentery fell by 16 in Edinburgh, but there was a rise of 10 in Glasgow. The fall in the incidence of scarlet fever was contributed by the western area, while in the eastern and south-eastern areas a small rise was reported.

In Eire a decline of 31 in the notifications of measles and a decrease of 20 for whooping-cough were reported. In Dublin C.B. a decrease was recorded in the notifications of measles 22, scarlet fever 12, and whooping-cough 10. In the country, excluding county boroughs, the notifications of whooping-cough rose from 9 to 39.

In Northern Ireland the notifications of whooping-cough increased by 50; the largest local rise was 31 in County Tyrone. Notifications of measles showed a decrease of 18 in County Antrim, and a rise of 12 in County Tyrone.

Week Ending March 5

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,189, whooping-cough, 2,653, diphtheria 10, measles 18,619, acute pneumonia 1,500, cerebrospinal fever 33, acute poliomyelitis 9, dysentery 65, paratyphoid 5, and typhoid 1.

No 8

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Feb. 26.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949					1948 (Corresponding Week)

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

Medical News

Professor Grey Turner

Professor G. Grey Turner has been elected an Honorary Foreign Member of La Société de Chirurgie de Lyon.

Lord Boyd-Orr

Sir John Boyd Orr, M.D. F.R.S., who was raised to the Peerage in the New Year Honours has assumed the name, style, and title of Baron Boyd Orr of Brechin Mearn in the County of Angus.

West Herts and Watford Centenary Dinner

The West Herts Medical Society was formed at the Rose and Crown Hotel, Watford on March 11, 1849. For many years the society remained essentially a dining club, but gradually, as its membership increased, meetings for the discussion of medical topics took pride of place and the dinners became of less importance. The Watford Medical Society was formed in 1896, and in 1912 the two societies amalgamated under the title "West Herts and Watford Medical Society." At the centenary dinner, which was held on Friday, March 11, the toast of the society was proposed by Dr. F. M. R. Walshe, F.R.S. and President Dr. J. W. C. Leech, replied. The health of the guests was proposed by Dr. F. J. Aldridge, Lord Moran, P.R.C.P., and Sir William Gilliat, P.R.C.O.G., replied. Lord Webb-Johnson should have replied, but was unfortunately unable to attend the dinner. Among the many guests were Sir Lionel Whitby, President of the British Medical Association, and Dr. H. Guy Dain, Chairman of Council. In the course of the evening tribute was paid to the work of Dr. C. Herbert Hall, who was one of the founder members of the Watford Medical Society and its first honorary secretary. He has continued to act as honorary secretary for a period of 55 years.

Medical Society of London

The 169th anniversary dinner of the Medical Society of London was held on March 8 with the President, Dr. T. Jenner Hoskin, in the chair. In proposing the health of the Society Mr. Bernard Darwin, who was the principal guest, compared real medicine with golfing medicine, drawing the moral that one should not overdo the cure. In reply Dr. Jenner Hoskin said that the society had been founded in 1773, its membership being made up of 30 physicians, 10 surgeons, and 10 apothecaries. To begin with the society had found its presidents among physicians, but lately physicians and surgeons had alternated in this office. It had been in its present home at 11, Chandos Street, since 1871, and now had a well-furnished council chamber as a result of the treasurer's activities. In toasting the visitors, Mr. E. W. Riches welcomed Mr. Darwin as a clubbable man. His great-great grandfather, Erasmus Darwin, had lived at the time the Medical Society of London was founded. In responding for the visitors Lord Moran replied in a felicitous speech which caught the atmosphere of the evening.

Wills

Dr. Charles Henry Milburn, O.B.E., of Harrogate, left £13,076. Apart from a few small bequests, he left the residue to his daughter for life, and on her death half to King's College, Newcastle-upon-Tyne, for a scholarship in medical jurisprudence for students born in Northumberland, Durham, or Yorkshire, and half to the British Medical Association for medical jurisprudence and forensic medicine prizes for registered medical practitioners. Professor Bertram Arthur Lloyd of Birmingham, left £19,808. He made a number of bequests, and left the residue in trust to his wife for life, with remainder as to half to the Royal College of Surgeons and half to the Cavendish Research Laboratory, Cambridge.

COMING EVENTS

Ophthalmological Congress

The annual congress of the Ophthalmological Society of the United Kingdom will be held at the Royal Society of Medicine (1 Wimpole Street, London W.) on Thursday, Friday, and Saturday, March 21 and April 1 and 2. The programme is as follows: March 21, 9.45 a.m. presidential address by Mr. F. A. Juller (1) "Some Points in the Operation for Acute Glaucoma" and (2) "Some Reflections on Refraction" followed by the presentation of the Bowman medals and a paper by Mr. D. N. Matthews on "The Technique of Plastic Operations in the Neighbourhood of the Orbit." 11.30 a.m. Mr. J. R. Wheeler, "The Reduction of Intra-ocular Tension by Curare, Retrobulbar Procaine and Diisopropyl Fluorophosphate." 12 noon, annual general meeting. 2 p.m., Dr. MacDonald Critchley, "The Problem of Awareness or Non-awareness of Visual Field Defects." 2.30 p.m., Dr. Critchley, "Cerebral Metamorphoses." 3 p.m., Mr. Eugene Wolff, "Notes on Normal and Pathological Ocular Pigment." 3.30 p.m., Dr. E. Hartmann,

"The Clinical Estimation of Pressure in the Retinal Arteries." 4 p.m., Dr. S. P. Meadows, "Internal Carotid Artery Aneurysms." 7.30 for 8 p.m., annual dinner of the society at Grosvenor House, Park Lane, London, W. (tickets 30s. each, inclusive of gratuities but exclusive of wines). April 1, 9.30 a.m., discussion on "Corneal Grafting" to be opened by Professor A. Franceschetti, Mr. J. W. Tudor Thomas, Professor G. P. Sourdille, Mr. B. W. Rycroft, and Mr. D. P. Choyce, 2 p.m., pictorial demonstration of short cases. April 2, 9.30 a.m., Mr. W. J. Wellwood Ferguson and Dr. Alastair G. Macgregor, "Congenital Total Colour Blindness, with Otosclerosis and Hypertension as Associated Hereditary Abnormalities." 10 a.m., Dr. A. C. Copper, "The Measurement of the Retrobulbar Resistance (Orbitonometry) in the Clinic." 10.30 a.m., Dr. G. Karpe, "Clinical Electroretinography." 11 a.m., Mr. J. Pike, "Some Problems in Ophthalmic Dispensing." 11.30 a.m., Dr. J. Berkson, "Retinal Arterial Spasm in Toxaemia of Pregnancy." 2.0 p.m., annual general meeting of the Faculty of Ophthalmologists at the Royal College of Surgeons of England, Lincoln's Inn Fields, London W.C. Further information may be obtained from the honorary secretary, the Hon. G. J. O. Bridgeman, F.R.C.S. 45, Lincoln's Inn Fields, London, W.C.2.

Society of Anaesthetists of the South western Region

The Society of Anaesthetists of the South western Region has arranged meetings to be held at Taunton on April 1 and 2, and at Plymouth on July 1 and 2. Anaesthetists from other areas will be welcome, and those wishing to attend should communicate with the honorary secretary, Dr. G. L. Feneley, Avon Lodge, 8, Parry's Lane, Bristol, 9.

Reunion Dinner

A reunion dinner of C.M.F./M.E.F. physicians will be held at Simpson's Restaurant, 100, Strand, London, W.C. on Saturday, April 2, with Dr. E. R. Cullinan in the chair. All interested should communicate with the honorary secretary, Dr. Arthur Willcox, 66 Harley Street, London, W.1.

Chesterfield Medal Examination in Dermatology

The Chesterfield Medal examination in dermatology will be held at St. John's Hospital for Diseases of the Skin, 5, Lisle Street, London, W.C., on Monday, Tuesday, and Friday, April 4, 5 and 8. Full particulars may be obtained on application to the dean of the Institute of Dermatology at the hospital.

International Medical Congresses

A General Constituent Assembly for the foundation of the Permanent Council for the Co-ordination of International Congresses of Medical Sciences will be held in Brussels from April 4 to April 9. This Conference is sponsored jointly by Unesco and WHO. More than 50 representatives of various international medical organizations will attend the Conference, which will be presided over by Professor J. Maisin to whom communications can be addressed at 141, Rue Belliard, Brussels.

Empire Rheumatism Council

The Empire Rheumatism Council has arranged a week-end course to be held at the Apothecaries' Hall, Black Friars Lane, Queen Victoria Street, London, E.C., on Friday, Saturday, and Sunday, April 8, 9 and 10, with the following programme: April 8, 4.30 p.m., Sir Adolphe Abrahams, "Rheumatism—A Symptom in Clinical Diagnosis." 5.30 p.m., Dr. George Graham, "Gout." April 9, 10 a.m., Dr. W. S. C. Copeman, "Non-articular Rheumatism." 11.15 a.m., Dr. Philip Ellum, "Rheumatoid Disease—Its Systemic Manifestations." 2 p.m., Dr. Bernard Schlesinger, "Acute Rheumatism." 3 p.m., Dr. Hugh Burt, "Spondylitis." 4.30 p.m., Dr. J. J. R. Duthie, "Fundamental Principles in the Treatment of Arthritis." April 10, 10 a.m., Dr. F. S. Cooksey, "Physical Methods in the Treatment of Rheumatic Diseases." 11.15 a.m., Mr. J. C. R. Hindenach, "Orthopaedic Aspects of the Rheumatic Diseases." The fee for the course is £2 2s., and entries (limited to 100) must reach the general secretary of the Council Tavistock House North, Tavistock Square, London, W.C.1, at least one week before the course opens.

SOCIETIES AND LECTURES

Friday

BRITISH INSTITUTE OF RADIOLOGY—(1) At Royal College of Surgeons of England, Lincoln's Inn Fields, London W.C. March 18, 2.15 p.m., joint meeting with Faculty of Radiologists and Radiological Section Royal Society of Medicine. "Tumours of the Kidney" by Professors R. A. Willis and A. S. Johnston. (2) At 32, Welbeck Street, London W., March 18, 5 p.m., Meeting of medical members. (3) At Royal Society of Medicine, 1 Wimpole Street, London W., March 18, 8.15 p.m., Continuation of joint meeting "Tumours of the Kidney" by Messrs. Twissington Higgins, R. Omer Ward and Miss M. D. Snelling.

Saturday

ST STEPHEN'S HOSPITAL (RHEUMATISM UNIT), 369, Fulham Road, Chelsea, S.W.—March 26, 10 a.m., "*Aetiology of Acute Rheumatism*," Introductory Address by Professor Bruce Perry 11 a.m., "*Modern Conception of the Aetiology and Classification of the Chronic Rheumatic Diseases*," by Dr. Philip Eilman 12 noon, "*Organization of a Rheumatism Unit, with Special Reference to the Management of Rheumatoid Arthritis*," by Dr. Francis Bach 2 p.m., "*Ward Round and Demonstration of Methods of Physical Treatment, Injection, and Plaster Technique*," by Dr. Bach 3 p.m., "*Social Welfare, Dietetics, Occupational Therapy, and Vocational Guidance*," by Dr. Bach and others 4.15 p.m., "*Clinical Pathology in the Rheumatic Diseases*," by Dr. A. for prolonged local medication

Penicillin Chewing Gum A&H presents penicillin incorporated in a base predominantly mint-flavoured and designed to maintain the potency of the medicament.

When chewed slowly it provides an effective concentration of penicillin in the mouth for three to four hours. It is thus the preparation of choice in the treatment of Vincent's infection, tonsillitis and other infections due to penicillin-sensitive organisms within the buccal cavity.

PENICILLIN CHEWING GUM A&H

In packets of six pieces, each piece containing 5,000 i.u. penicillin (calcium salt)

ALLEN & HAMBURYS LTD LONDON E.C.2

Crookes AURO-CALCIUM

The calcium salt of aurothiomalic acid (Auro-Calcium) is finding an ever increasing use and is now widely recognised as a substantial contribution to chrysotherapy. The demand for the booklet "Crookes Gold Products" has necessitated a still further edition (the 4th), available on application.

safer sulphonamide therapy with

TRADE MARK **'SULPHATRIAD'** BRAND
compound sulphonamide tablets

sulphathiazole	..	0.185 gramme
sulphadiazine	..	0.185 gramme
sulphamerazine	..	0.130 gramme

Since the solubility in the urine of each of the constituents of 'Sulphatriad' is not affected by the presence of the other two, the risk of crystalluria during the treatment with this combination of sulphonamides is greatly reduced.

'Sulphatriad' may be employed whenever chemotherapy with sulphonamides is indicated and is available in containers of 25, 100 and 500 x 0.5 gramme tablets.

An Ideal Stand-by in **WASTING DISEASES**

TO replace the tissue wastage and decrease in energy associated with wasting diseases is a problem often rendered more difficult by the fact that there is frequently an associated anorexia and enfeeblement of the digestive and assimilative processes.

'Ovaltine' has proved to be the ideal stand-by in many such cases, because it is an energising and reconstructive nutrient, complete in all essential food elements. It is almost invariably well tolerated even by disordered stomachs and is practically completely absorbed into the blood stream.

The unique dietetic value of 'Ovaltine' is derived from its content of important food substances—milk, eggs, malt extract, cocoa and soya.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Pertussis Prophylaxis and Treatment

Q.—What are the current views on the prophylaxis of pertussis by means of (a) pertussis vaccine, (b) combined diphtheria and pertussis vaccine, (c) gamma globulin prepared from hyperimmune serum. My experience of (a) has been unsatisfactory, and I feel that something more active should be available for treatment of this condition, particularly in infancy. If (b) is reliable should it not be made available at child-welfare clinics? In my area no mention of the combined therapy has been made at the local clinic.

A.—(a) Distinction must be made between the use of pertussis vaccine for the protection of a susceptible child and for the treatment of a case. Prophylactic injections of pertussis vaccine in young children have given variable results, probably because of variation in antigenic potency, which until recently could not be assayed in a suitable experimental animal as, for example diphtheria toxoid is. Lately intranasal instillation or intracerebral inoculation has proved suitable for infecting mice with relatively small doses of *Haemophilus pertussis* and it is hoped that assessment of the protective value of pertussis vaccine in mice may give some guidance to its prophylactic value in children. Pertussis vaccine given early in the infection in small doses at frequent intervals has been claimed, particularly by Danish doctors, to abort or ameliorate an attack of pertussis. Injections of vaccine later in the disease have no beneficial effect and may even aggravate the condition.

(b) When combined diphtheria toxoid and pertussis vaccine produce an antibody response as good as, or better than, the reagents used singly. If both are good antigens, combined vaccination has obvious administrative advantages. Unfortunately there is still uncertainty about the efficacy of pertussis vaccine and the combination of a good and a poor antigen might bring the good antigen into disrepute. Until, therefore, we are satisfied that pertussis vaccine will give reasonably good protection it may be wiser to use these two prophylactics separately. Another difficulty is that protection against pertussis should be given as early in infancy as possible, say at 2 to 3 months of age, since the infection is not uncommon and often severe in the first year of life. Diphtheria, on the other hand, is relatively rare in infants so that diphtheria immunization is usually given at 9 to 12 months, when the child's antibody response seems to be better than in the first few months of life. Combined diphtheria toxoid and pertussis vaccine is available commercially, but the decision about its use in child-welfare clinics rests with the medical officer of health and his health committee.

(c) Gamma globulin prepared from hyperimmune serum is not available in this country, but American experience with large repeated doses (two or three injections of 20 ml) of unconcentrated hyperimmune serum suggests that it is reasonably effective in protecting household contacts intimately exposed to infection.

Konsuloff Pregnancy Test

Q.—Can you give me any information about the Konsuloff test for pregnancy? I am not interested in precise details of the technique but would like to know the species of frog used and the site of injection, also the physiological explanation of the relation of the pituitary to skin colour, and if this has any counterpart in the human.

A.—The test was first described in 1934 by Konsuloff,¹ of Sofia who found that the melanophore hormone is increased in amount in pregnancy and excreted in the urine. In his original experiments he used *Melanosstomus* the unne being added to the water in the tank and absorbed through the fish's gills. A darkening of colour was noticed in twenty minutes, but as the fish themselves produce a melanophore hormone the

results were unreliable. *Rana esculenta* were used for subsequent experiments. After being submitted to hypophysectomy the frog is allowed to recover for two weeks, and may then be used repeatedly for testing. Injection of 2.5 ml of urine is made into the dorsal lymph sac, a control frog is given an injection of urine from a non-pregnant woman. A maximum olive-green colour with dark-brown flecks is obtained in two hours. In a later paper Konsuloff² concludes that the test is diagnostic for pregnancy.

Zondek³ isolated a melanophoric hormone from the intermediate lobe of the pituitary. This hormone, which he called intermedin, stimulates the expansion of chromophores in cold blooded animals, but appears not to have a corresponding effect in man. The adrenaline content of the adrenal may be reduced by intermedin, but this finding has been doubted. It should be added that Zondek failed to confirm that there is an increase in the amount of this hormone in the urine during pregnancy.

Undulant Fever and Milk Regulations

Q.—A case of undulant fever has recently occurred in this district, and the patient is supplied with milk from the same herd as is my household. At present all our milk is being boiled. Should we take any other precautions? Is the public health authority charged with any duties in connexion with the herd?

A.—The inquirer should certainly continue to boil the milk until he hears that it is being pasteurized. Under Article 18 of the Milk and Dairies Regulations the local medical officer of health has power to stop the sale of milk if it has caused illness in man or is known to be infected. Unfortunately it is difficult to prove that any one case was due to a particular supply, and it takes several weeks to prove that any particular sample was infected, also the intermittency of the disease in cattle sometimes results in a series of negative samples being obtained following strong suspicion of infectivity. If the local authority is unable to prove its case it may be required to pay a farmer or dairyman full compensation for his losses. The effect is, in practice, that it is very difficult to stop a milk supply, however strongly suspected of causing undulant fever in man, if the farmer or dairyman is not willing voluntarily to do this or to arrange for pasteurization.

Cup Arthroplasty

Q.—Is the operation of arthroplasty for osteoarthritis of the hip, with the use of a 'cup,' now considered worth while? If it is successful how long is it likely to remain so and in what proportion of cases? In those cases in which the improvement is not maintained, what is likely to happen and in how many years?

A.—Experience has shown that in carefully selected cases the operation of "cup" or "mould" arthroplasty is well worth while. One factor that is essential to success is the full and intelligent co-operation of the patient in carrying out the arduous course of post-operative exercises, which calls for a high degree of pertinacity. Similarly, the surgeon must be prepared to exercise a close personal supervision during all stages of the treatment. Patients who are grossly overweight, flabby or excitable are unsuitable subjects for the operation. A further factor that has an important bearing on the prognosis is the nature of the disability for which treatment is sought in osteoarthritis of degenerative or traumatic origin: the outlook is good, but in "infective" conditions, such as ankylosing spondylitis and rheumatoid arthritis, it is poor. In brief, the type of case in which cup arthroplasty achieves its greatest usefulness is that of bilateral osteoarthritis of the hips in an otherwise vigorous, intelligent, and co-operative patient.

When the operation is successful there are grounds for hoping that the result will be lasting; but our knowledge on this point will not be complete until really long-term reviews of large series of operations become available. In the most favourable cases steady improvement continues for two years or more, and later deterioration does not occur. Satisfactory function is

known to have been maintained for over ten years. But good results are, unfortunately, not to be expected in every case—perhaps in not much more than two-thirds of them at the present time, taken by and large. Early failure may be due to inadequate surgical technique, inefficient after-treatment, or lack of co-operation by the patient. Unsatisfactory late results may be associated with persistent pain or with progressive decrease in the range of movement. Again, this may sometimes be attributed to errors of technique; but other factors, not completely under the control of the surgeon, may be responsible; thus in ankylosing spondylitis re-ankylosis round the cup has often occurred, and even in more favourable conditions, such as osteoarthritis, there may be much new bone formation which limits movement. In other cases there has been subluxation of the cup, or occasionally absorption of the femoral neck with "settling" of the cup. In most of the unsuccessful results evidence of failure has been present at a relatively early stage, certainly within the first two years.

Falling Hair

Q.—(a) Are female glandular preparations ever beneficial in the treatment of falling hair of the scalp? If so, how are they given? (b) Is oestrogen of any use in the treatment of premature loss of hair in otherwise healthy young men? If so, how is it administered, and are there any contraindications?

A.—(a) From an endocrinological point of view we have the following basic evidence. Loss of hair of the scalp occurs normally in a large proportion of virile men in the third and fourth decades, or later, and it also occurs in virilism in females, when there is a known excess of androgens, from which it is concluded that androgens increase facial and body hair but decrease scalp hair. On the other hand, eunuchs and eunuchoids tend to retain their scalp hair throughout life. In Simmonds's disease in women, in which there is a great decrease in androgens and oestrogens, and the hair becomes thin and its lustre and colour, oestrogens are potent in restoring more normal condition of the scalp hair (Simpson, S. L., *R. Soc. Med.*, 1948, 12, 192). Oestrogens may be given mouth, injection, or implantation, and can be used by inunction. Scalp hair is also lost in myxoedema and restored by thyroid. The writer has no experience of the use of female glandular preparations in idiopathic baldness in the absence of endocrinopathy. They are not effective in alopecia.

(b) The remarks in (a) above are applicable to this question, and the probable answer is in the negative. The effect of oestrogens in adequate dosage in the male is to produce involution or atrophy of the testes, loss of libido, and gynecomastia. These effects are spontaneously reversible if therapy is not unduly prolonged. Their production is justified in the treatment of a condition such as carcinoma of the prostate.

Stilboestrol and Dienoestrol

Q.—What are the inorganic constituents in tablets of stilboestrol and of dienioestrol?

A.—In tablets of stilboestrol and of dienioestrol there are no inorganic constituents. Some lactose is, however, usually present as a diluent.

Retroversion of the Uterus

Q.—What treatment is recommended for a 27-year-old multipara with a retroverted uterus? If there are no symptoms, is it advisable to leave the condition untreated and warn the patient to report immediately she becomes pregnant?

A.—No treatment is indicated if the patient is free from symptoms, but in the event of her becoming pregnant she should be asked to return for examination before the twelfth week. This is to make sure that the uterus corrects its position spontaneously; if it has not done so by the tenth to twelfth week it should be manipulated into anteversion and maintained in that position by a suitable pessary. Some authorities say that, provided the patient never lets her bladder get overfilled, the uterus always corrects itself and there is no need for any treatment even in pregnancy. Nevertheless, impaction does occur, and there is a good deal of evidence that abortion is more likely, so it seems wise to take no chances, particularly as restoring the position of the uterus at the tenth week is such an easy manoeuvre.

Subarachnoid Haemorrhage

Q.—Some months ago a female patient had a subarachnoid haemorrhage from which she recovered. It has now been suggested that she should submit to a tying-off of the artery. Is this operation often undertaken, which artery is most often concerned, and what are the results?

A.—In the absence of gross cardiovascular disease, subarachnoid haemorrhage is most frequently due to a congenital intracranial aneurysm. Before carotid ligation is undertaken the case should be investigated by carotid angiography on each side. If the angiograms show no lesion there are several possibilities: (1) there is no aneurysm; (2) there is an aneurysm which is not fed by the internal carotid artery (for example, an aneurysm of the vertebral or basilar artery or one of their branches); (3) there is an aneurysm on the internal carotid system which has filled with clot. If the angiograms reveal an aneurysm and it is already eight weeks or more since the original subarachnoid haemorrhage, the risk of further intracranial haemorrhage is probably about 20%, though the figures on which this estimate is based are not large. If the aneurysm lies below the level of the anterior clinoid processes it is best treated by carotid ligation after an angiographic test has demonstrated that both cerebral hemispheres can be adequately supplied from the carotid system of the opposite side. It is safer to ligate the common carotid than the internal carotid, though in patients in the younger age groups in whom angiography has demonstrated an adequate collateral circulation from the opposite side the latter operation carries little risk. So far as is known to date carotid ligation is effective in preventing further attacks of haemorrhage. In some cases the angiograms will show not an aneurysm but an angiomatous malformation of the central hemisphere as the cause of the subarachnoid haemorrhage. For this condition carotid ligation is useless.

Boeck's Sarcoidosis

Q.—What are the microscopical appearances of lymph nodes affected with Boeck's sarcoidosis, and what are the prognosis and treatment in this condition?

A.—There is usually a well-defined mass of endothelioid cells with little or no tendency to caseation or calcification and few or no giant cells and no surrounding reaction. A diagnosis cannot, however, be made on histological appearances alone. Treatment is by calciferol in a dosage of 100,000 to 150,000 i.u. daily over long periods, but care must be exercised and biochemical control is desirable. Disturbances of calcium metabolism and of renal function may occur. Prognosis is good; in the majority of cases the disease resolves or becomes stationary.

NOTES AND COMMENTS

Home-cured Tobacco and Amblyopia.—Dr. A. E. BURROUGHS (Oswestry) writes: With reference to the question headed "Home-cured Tobacco and Amblyopia" ("Any Questions?" Jan. 22, p. 163), most of the tobacco amblyopic patients I have seen in a long ophthalmic experience have been pipe smokers over 60 years of age, and retired—therefore having time on their hands, and not much to do, so smoking to excess. I have not seen more than two cases of amblyopia in men smoking only cigars. With regard to home-cured tobacco, the midribs of the leaves should always be removed, and if the dried leaves be then soaked in several changes of water nearly all the nicotine is dissolved out. This soaking does not affect the taste of the tobacco.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 19 1949

THE SECRETARY REPORTS

PROPOSED TERMS FOR HOSPITAL STAFFS

The proposed terms and conditions of service for hospital medical and dental staffs just issued by the Ministry are published in full in the following pages. The object of these notes is not to comment on the proposals but to draw attention to some of the more important points and to their implications. These notes are in no way a substitute for the full and detailed scheme of proposals which should be studied by every consultant and specialist as well as by other hospital officers.

The scales of remuneration proposed by the Government are, of course, based on the scales recommended by the Specialist Spens Committee. Two adjustments are made in the conversion of the Spens proposals to the Ministry's proposals. Roughly speaking, a betterment factor of 20% is added, and then a deduction of 8% is made in respect of the Government contribution to superannuation (to compound these two figures an increase of approximately 11% is needed). In fact, the betterment which has been applied varies from 18.8% to 22.4% in the case of specialists and from 17% to 20.5% in the case of trainee specialists. The rates of remuneration are to be retrospective to July 5, 1948, for those who were in the hospital service on that date. The incremental date for such officers is July 5, the first increment being due on July 5, 1949.

Specialists

Once a practitioner is recognized and appointed as a specialist his salary proceeds automatically by incremental stages to the maximum of £2,750 (non-residential). Specialists taken over on the appointed day will be placed at the level on the scale which they would have reached had the Service been operating throughout their specialist career. Allowance can be made for service with H.M. Forces. There is no definition of a specialist. The effect of this is that the decision by a board of governors or a regional hospital board to appoint a practitioner to a specialist post on a hospital staff confers specialist status. To this extent the number of specialists is controlled by the establishment of specialist posts as well as by the fitness of an applicant to fill such a post.

Special Awards

It appears that the Ministry accepts the recommendation of the Spens Committee that 4% of all specialists in the Service should receive additional remuneration of £2,500 per annum, 10% additional remuneration of £1,500 per annum, and 20% additional remuneration of £500 per annum, though it is not clear what significance should be attached to the words in para. 1(b) of the Ministry document: "... having regard to the desirability that 4% of all specialists ...". The special awards will be subject to superannuation, so carrying the Government contribution of 8%, but no betterment as such is paid on them. As superannuation is applied to the special awards it is inferred that they will continue until the age of retirement.

Trainee Specialists

The Trainee Specialist section needs no amplification except to stress that promotion from one grade to another will not be automatic, each grade demanding a distinct level of ability and experience.

House Officers

The rates for house officers of £350, £400, and £450 per annum are subject to a deduction of £100 a year for residential emoluments, each post being tenable for six months.

Hospital Medical Officers

The grades of Junior Hospital Medical Officer and Senior Hospital Medical Officer were not the subject of specific recommendations in the Spens Report. The junior grade is for posts of lesser responsibility in hospital including, no doubt, senior resident posts not graded as trainee specialist posts. Senior Hospital Medical Officers, on the other hand, are defined as senior officers performing clinical duties who are not of specialist status and not trainees, a scale of £1,300 per annum at the age of 32, rising by annual increments of £50 to £1,750 (non-residential), being recommended. This scale, unlike the Junior Hospital Medical Officer scale, will be used—by the application of a formula—for part-time as well as whole-time hospital posts. Presumably this grade will be used for certain practitioners whose hospitals were taken over on the appointed day but who are not graded as specialists. For example, it may include former whole-time officers in the municipal hospital service, some medical officers of infectious-diseases, tuberculosis, and venereal-disease services, and members of former voluntary hospital staffs not graded as specialists. It is understood that it is intended that this group shall decline in dimensions as the years proceed. The application of the Spens formula (see below) to part-time members of hospital staffs not graded as specialists yet continuing with their hospital work at the age of 41 will result for most such practitioners in an annual payment per weekly half-day worked of approximately £200 a year. The decision whether a practitioner on a hospital staff is of specialist status or not will be a matter for boards to determine on the advice of Review Committees now at work. It is significant that, to the extent to which such practitioners are graded as Senior Hospital Officers and not as specialists, to that extent will the aggregate number of special awards decrease, for the number is directly related to the number of specialists.

Medical Superintendents and Deputy Medical Superintendents

Further consideration is promised of the position of medical superintendents of mental hospitals and mental deficiency institutions. For the rest, some medical superintendents and deputies will no doubt be graded as specialists. Those so graded will be remunerated as specialists for the proportion of their time they devote to their specialty and as administrative staff for the proportion of their time which they devote to administration. The one qualification to this is where the proportion of time devoted to administrative duties is small, in which case the specialist remuneration will obtain. In other cases the effect of this proposal in the case of the specialist administrator devoting more than a small proportion of his time to administration is that his remuneration will be less than the specialist level and so may be less than that of practitioners on his staff devoting the whole of their time to their specialty. There is a scale for hospital administrative staff which in effect is the scale applied to secretaries of hospital management committees. This is a range of remuneration between £580 and £1,700, the appropriate place in the range being determined on a points system related to such factors as the number of beds. This is the scale which is to be applied to medical superintendents engaged wholly in administration; subject to the proviso that those who were transferred under Section 68 of the Act and who were receiving salaries better than those now introduced are entitled to retain their previous salaries on a personal basis for so long as they remain in the same appointment or another appointment of the same or greater responsibility as the one they held at the appointed day. As new medical superintendents engaged whole-time in administration are appointed, their remuneration will be on the scale applicable to the lay secretaries of hospital management committees.

Part-time Specialist Appointments

There is to be no clocking in and clocking out. Before the permanent contract is entered into an assessment will be made

of the amount of time necessary to perform the duties attaching to the post, this time assessment taking into account practically all varieties of service as well as travelling time. But it will exclude time spent in emergency calls to patients in beds in the charge of the specialist (except where any exceptionally heavy liability to recurring emergency work of this sort is anticipated). It will also exclude the time spent in committee work or in the care of private patients and any domiciliary visiting for which separate fees are payable. The additional sum completed, it will be divided by $3\frac{1}{2}$ hours to give the number of notional half-days, the specialist being given the benefit of "the marginal overlaps." If, in the case of an individual specialist, the number is x , his remuneration will be

$$\frac{x}{11} + \frac{\frac{1}{2}x}{11} \text{ or } \frac{x}{11} + \frac{\frac{1}{2}(11-x)}{11},$$

whichever is the less, of the appropriate whole-time salary. In other words, the specialist calculated as doing x sessions a week will get x elevenths of the annual salary applicable to him plus one-quarter of the resultant figure except where the number of sessions is high, in which case the element of addition is shaded down so as to keep the remuneration of a part-time officer less than that of a whole-time officer. An overriding maximum of $9\frac{1}{2}$ elevenths is applied to all part-time officers, though this maximum does not include payments for exceptional consultations for a board with whom the practitioner is not in contract, payments for work as locums, and payments for domiciliary visits. A similar formula is applied to those graded as senior hospital medical officers.

There are provisions in paragraph 5(c) of the proposals for additional payment for exceptional consultations for specialists, retired consultants, and general practitioners. There is provision for paying a locum at the rate of 5 guineas per half-day during a specialist's temporary absence where other arrangements cannot be made.

Boards are given discretion, with the Minister's consent, to offer a higher rate of part-time remuneration in special circumstances.

Domiciliary Visits

In general the rate is £4 4s. per consultation, with an additional £2 2s. where an operative procedure, other than an obstetric one, is undertaken or where the specialist uses his own electrocardiograph or portable x-ray apparatus; there is an additional fee of £4 4s. for an obstetric operation. An additional £1 1s. will be paid for a journey of over 20 and up to 40 miles radius, £2 2s. for a journey of over 40 and up to 60 miles radius, and so on, with an additional £1 1s. for every 20 miles. The maximum remuneration for domiciliary visiting, apart from travelling and additional mileage payments, is 200 guineas in any quarter or 800 guineas in any year, whichever the specialist prefers. No special payment is to be made to whole-time specialists for domiciliary work.

General Practitioner Staffs

There are special sections devoted to the remuneration of general practitioners on the staffs of hospitals in that capacity and to general practitioners employed at hospitals (paragraphs 8 and 9).

Tenure of Post

There is no fixed tenure of post to be specified in the contract. The board is the body which appoints and the body which terminates an appointment. There is no statement of the reasons for which a board can properly terminate an appointment. Where a board is proceeding to terminate an appointment of a specialist he is entitled to send a full statement to the Minister, who would, after consulting the board, place the case before a professional committee (consisting of representatives of the Ministry and representatives of the profession, under the chairmanship of the Chief Medical Officer) for their advice. In the light of the advice of this professional committee the Minister will confirm the termination of service, or direct reinstatement, or arrange some other solution. This procedure is to be completed before the board's decision to terminate the appointment is carried into effect.

Strictly speaking, there is no right of appeal conferred on the practitioner; nor does the document say that a board can dismiss only with the permission of the Minister. Once the

board is in process of terminating an appointment, the specialist affected can invite the Minister to intervene. But it seems the process of dismissing must have begun.

Leave

On the subject of annual leave, compassionate leave, and sick leave there can be no substitute for a meticulous scrutiny of the details of the Ministry's document (paragraph 16).

Expenses

The general principle is laid down that travelling, subsistence, and other expenses are to be paid to meet the actual disbursements of practitioners and not to be regarded as a source of emolument or reckoned for pension purposes. Some more important points are as follows:

(a) Officers will be classified as regular users or casual users, according to whether their annual official mileage is estimated to exceed 2,000 miles or not.

(b) The regular user, whatever the horsepower of his car, will be paid an annual allowance of £52, with 3½d. a mile in addition.

(c) Casual users will receive no annual allowance but will be paid 7½d. a mile for the first 3,120 miles per year and 3½d. a mile thereafter.

(d) Where an officer uses a private motor-car in circumstances where travelling by a public service would be appropriate, the mileage allowed to him is 1½d. a mile, irrespective of the type of vehicle.

(e) Subsistence allowances are at one rate if the practitioner's remuneration is £760 a year or more and at another rate if the practitioner is receiving less than £760 a year.

Medical Examination on Appointment

The passing of a medical examination is a condition of appointment of all officers within the scope of the N.H.S. superannuation scheme, other than those who are transferred under the Act. The superannuation scheme itself makes no provision for a medical examination. Nor has there been any suggestion yet of a medical examination for those entering the general practitioner service.

It will be observed from the wording of paragraph 18 of the Ministry's document that the passing of a medical examination is a condition of appointment, as distinct from a condition of entry to the superannuation scheme. In practice this will mean that, on obtaining a registrable qualification and seeking a post as junior house officer, a practitioner will be required to satisfy an examining doctor that he is "free from any physical defect or disease which now impairs his capacity satisfactorily to undertake the duties of the post for which he is a candidate." This is not without the danger, however small, that a practitioner may find himself on the *Medical Register* without the possibility of obtaining house appointments or any other posts in the hospital service.

Appendices

Appendix A deals with the subject of remuneration of whole-time clinical posts in medical and dental schools and part-time clinical teaching posts. In the case of the latter, no rates of remuneration are given, it being stated that they will be remunerated by the university or school in recognition of their teaching duties "at a rate which appears to the university or school to be appropriate to those duties."

In Appendix B there are listed the services which are within the scope of the hospital and specialist services and those which are not. Included among those which are not within the scope, and for which, therefore, remuneration may be received, are examinations and reports required by employers on employees, reports required in connexion with legal actions, examinations and reports for coroners, life insurance reports, certificates under the Blind Persons Act, attendance at court hearings as medical witnesses, lectures given to nurses, and services as members of medical boards.

Appendix C describes what comes within the ambit of "study" leave, which incidentally cannot be claimed as a right, defining different kinds of leave with pay or expenses, with pay but without expenses, and without pay or expenses. It deals generally with the question of payment of expenses, imposing maxima which regional hospital boards and boards of governors are required to observe.

National Health Service

PROPOSED TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL AND DENTAL STAFF

NOTES. (a) *The terms and conditions of service set out in this document apply to England and Wales. They apply also to Scotland subject to minor adjustments to meet different circumstances in that country.*

(b) *All salary scales will apply equally to men and women, and uniformly throughout England, Wales, and Scotland.*

(c) *Under the National Health Service Superannuation Scheme, over and above any salary specified in this document the employing authority will be paying a contribution equal to 8% of the salary into the superannuation fund. The employee's contribution (6%) will be deducted from remuneration.*

1. Specialists

(a) Main Scale for Staff Specialists at Hospitals, including Dental Specialists

(1) Specialists appointed at age 32:

£1,700 . £125-£2,075 × £150-£2,375 × £125-£2,750 per annum non-residential.

(2) Specialists appointed at age 31 or earlier to start at £1,550 or £1,400 respectively.

(3) Specialists first appointed after age 32:

the hospital authority to be able to fix the starting salary at any of the four next incremental points in the scale,

(i) by reason of age, special experience, and qualifications,

(ii) by reason of age alone, where seniority has been lost because of service with H.M. Forces,

provided that the starting salary shall in no case be higher than the specialist would receive on age alone.

(b) Special Distinction Awards

An Advisory Committee on Awards for Consultants and Specialists has been set up to advise the Minister of Health and the Secretary of State for Scotland which specialists engaged in the National Health Service should receive awards for professional distinction, having regard to the desirability that 4% of all specialists in the Service should receive the highest award (£2,500 per annum in addition to the "basic salary"), a further 10% should receive the second award (£1,500 per annum), and a further 20% the third award (£500 per annum). These awards will be paid as an element of remuneration additional to the main scale and will be superannuable.

2. Trainee Specialist Grades (including Dental)

(a) *Grade 3* (as defined in the Spens Report on the Remuneration of Specialists: posts obtained normally not less than one year after registration and held normally for one year only):

£670 per annum non-residential.

(b) *Grade 2* (posts obtained normally not less than two years after registration and held normally for two years):

£775 per annum non-residential in the first year;

£890 per annum non-residential in the second and any subsequent years.

(c) *Grade 1* (posts obtained normally not less than four years after registration and held normally for three years):

£1,000 per annum non-residential in the first year;

£1,100 per annum non-residential in the second year;

£1,200 per annum non-residential in the third year;

£1,300 per annum non-residential in any subsequent years.

NOTES: Trainee specialists not to proceed from one grade to another by automatic promotion. Each grade of post demands a distinct level of ability and experience. A trainee specialist in a lower grade to be considered on merit, along with other applicants, for a vacancy in a higher grade.

A trainee specialist holding an appointment in Grade 1 and subsequently appointed to a Grade 2 post to be paid the higher salary appropriate to Grade 2 (i.e., £890 per annum) whilst he holds the post in that grade.

3. Other Non-Specialist Grades

(a) Junior House Officer (including Dental):

£350 per annum non-residential for the first post held;

£400 per annum non-residential for the second post held;

£450 per annum non-residential for the third and any subsequent post held;

with, in each case, a deduction of £100 per annum in respect of residential emoluments. Each post to be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) *Junior Hospital Medical Officers*, who have held house appointments but who are not trainee specialists, and who have less responsibility than other hospital officers of non-specialist status:

£700 (for an officer appointed not less than two years after registration) × £50-£1,000 per annum non-residential.

(c) *Senior Hospital Medical Officers*—senior officers performing clinical duties who are not of staff specialist status but are not trainees:

£1,300 per annum (at age 32) × £50-£1,750 (non-residential),

the position on this scale to be determined by age (subject to paragraph 10(b) below).

(d) Medical Superintendents and Deputy Medical Superintendents

The objective will be to reduce to a minimum the time to be given by medical staff to administrative duties, and to enable them to devote their energies to clinical work in their appropriate grade. Subject to further consideration in the case of mental hospitals and mental deficiency institutions, medical superintendents and deputies to be remunerated for clinical work as specialists or senior hospital medical officers according to their grading; for administrative work, to be remunerated at the appropriate rate for hospital administrative staff; where, however, a whole-time officer is engaged almost wholly in clinical work and gives only a small proportion of time to administrative duties, his appropriate clinical remuneration not to be affected.

4. Transferred Officers

Officers who were transferred under Section 63 of the National Health Service Act, 1946, and who immediately before July 5, 1948, were receiving salaries better than those now introduced, to be entitled to retain their previous salary on a personal basis for so long as they remain in the same appointment or another appointment of the same or greater responsibility as the one they held at the appointed day; but otherwise to conform to the new rates of remuneration on taking up a new appointment or on promotion.

5. Part-time Appointments, etc.

(a) Part-time Specialist Appointments

Before offering a part-time specialist appointment the board to assess in terms of hours per week what is the average amount of time required by an average practitioner to perform the duties attaching to the post. In assessing the average amount of time to perform the duties attached to the post, to take into account

out-patient clinics, ward rounds, operating sessions, laboratory work, and so on in their hospitals, including occasional visits to outlying hospitals for consultation, diagnosis or operative work. Also to include time given, e.g., as consultant adviser to the board on special branches of the service or by way of "pastoral visits" to cottage hospitals; and time necessarily spent in travelling from home or private consulting-room (whichever is the nearer) to the hospital or hospitals served (unless the journey is one which he would undertake irrespective of his work for the board). To exclude time spent in emergency calls to patients in the beds in their charge (except where any exceptionally heavy liability to recurring emergency work of this sort is anticipated), or in committee work, or in care of private patients in pay-beds or as out-patients. Also to exclude domiciliary visiting, for which special fees are payable (see paragraph 6 below).

The object is to express this aggregate number of hours per week as a number of notional "half-days" per week. It will not be necessary at any time to "clock in" the actual number of hours worked on any particular day or in any particular week by any particular specialist—the number of "half-days" is merely the means of expressing the duties attaching to the post in terms which enable remuneration to be calculated without meticulous adjustments up or down from time to time.

To arrive at the number of notional "half-days" from the aggregate of hours so assessed, the total to be divided by $3\frac{1}{2}$, the specialist being given the benefit of the marginal overlaps. In other words, the relation of "half-days" to hours to be as follows:

No. of hours weekly	No. of notional half-days on which salary will be reckoned
Up to $3\frac{1}{2}$	1
Over $3\frac{1}{2}$ and up to 7	2
" 7 " " " $10\frac{1}{2}$	3
" $10\frac{1}{2}$ " " " 14	4
" 14 " " " $17\frac{1}{2}$	5
" $17\frac{1}{2}$ " " " 21	6
" 21 " " " $24\frac{1}{2}$	7
" $24\frac{1}{2}$ " " " 28	8
" 28	9

The part-time salary to be determined by applying to the number of half-days calculated in this way the formula recommended in the Spens Report on the Remuneration of Consultants and Specialists, i.e., the part-time salary to be the following proportion of the whole-time salary appropriate to the specialist:

$$\frac{\text{number of half-days}}{11} + \frac{\text{one-quarter of number of half-days}}{11}$$

$$\text{or} \quad \frac{\text{number of half-days}}{11} + \frac{\text{one-quarter of } (11 - \text{number of half-days})}{11}$$

whichever is the less, subject to the maximum referred to in (e) below.

[Example of application of above:

A physician divides his time as follows:

Work	Estimate of time required by an average practitioner	Total weekly time (in hours)
Out-patient clinics	2 hrs. weekly + $\frac{1}{2}$ hour's travelling in each case*	4 $\frac{1}{2}$
" Pastoral visits " to cottage hospitals	One day of seven hours fortnightly, including travelling*	3 $\frac{1}{2}$
Irregular hospital visits	2 hours weekly, including travelling*	2
Charge of beds	9 hours weekly, + $\frac{1}{2}$ hour's travelling daily for 6 days*	12
Adviser to Board	8 hours monthly	2
	Total	24
		= 7 "half days"

For this the physician would receive eight-elevenths of the appropriate whole-time remuneration, i.e., $\frac{7}{11} + \frac{(11-7)}{44} = \frac{8}{11}$.

(b) Part-time appointments as Senior Hospital Medical Officer

The above formula for arriving at part-time salaries to be applied to all part-time appointments as Senior Hospital Medical Officer.

*Travelling time would of course depend on the particular circumstances of the individual concerned.

(c) Exceptional consultations

Specialists, who have no contract with the board, but who are called in exceptionally to hospitals or clinics for a special visit (e.g., because of their unusual experience or interest) to be paid at the rate of 5 guineas per visit (including any operative work, etc.).

As a normal practice, retired consultants to be offered honorary (unpaid) appointments in respect of exceptional calls on their services of this kind which would give them in return the right to use private pay-beds from time to time (see paragraph 13 below).

A general practitioner not on the staff of a hospital but called in exceptionally to render a specific service in emergency to be paid at the rate of £2 per visit, unless he is debarred from accepting remuneration by his terms of service under Part IV of the Act.

(d) Locum tenens arrangements

Normally, leave periods to be covered by the normal contract of service providing for practitioners to deputize for each other. Payment at the rate of 5 guineas per half-day, however, to be made to a locum engaged by a board during a specialist's temporary absence when it is impossible to arrange for his work to be adequately performed by other members of the board's staff within the terms of their contract of service.

A locum engaged by a hospital authority during the temporary absence in similar circumstances of a general practitioner holding an appointment of the kind described in paragraph 8(b) below to be paid at the rate of $3\frac{1}{2}$ guineas per half-day.

(e) Maximum remuneration for part-time appointments

The maximum remuneration for part-time appointments to be $9\frac{1}{2}$ elevenths of the whole-time salary appropriate to the grade.

This maximum not to include payments made to a specialist in respect of exceptional consultations performed for a board with whom he is not in contract; payments made in respect of work as locum tenens; and payments for domiciliary visits, referred to in paragraph 6 below.

Where a specialist holds part-time appointments with more than one board, which together are not equivalent to a whole-time appointment, this maximum to apply to the aggregate remuneration from all the boards concerned.

(f) In special circumstances a board, with the Minister's consent in each case, to have discretion to offer a higher rate of part-time remuneration than that normally applicable.

6. Domiciliary Visits

(a) Payment to be made separately for domiciliary visits by part-time specialists, but no additional payment for whole-time specialists (the basis being that the whole-time duties will be adjusted to include domiciliary visiting where required). Payment to be on the following basis:

Fee for consultation, 4 guineas, with an additional fee of

(1) 2 guineas where any operative procedure other than obstetric is undertaken or where the specialist uses his own electrocardiograph or portable x-ray apparatus;

(2) 4 guineas for an obstetric operation;

the additional fee of 2 guineas or 4 guineas to be payable once only in respect of each patient for the current illness.

(b) Boards to make payments, additional to the fee for the visit and to the normal travelling and subsistence expenses, of 1 guinea for a journey of over 20 and up to 40 miles radius, 2 guineas for a journey of over 40 and up to 60 miles radius, and so on, with an additional guinea for every 20 miles.

(c) Maximum remuneration under this head (excluding travelling and subsistence allowances and additional mileage payment) to be 200 guineas in any quarter or 800 guineas in any year, whichever the specialist prefers.

7. Clinical Specialists engaged in Teaching

See Appendix A.

8. General Practitioners on the Staffs of Hospitals in that capacity (part-time)

(a) General practitioner hospitals (cottage hospitals)

Remuneration in respect of services rendered other than those paid for by the executive council: the hospital management committee to create a staff fund by making a payment of £25 per annum for each bed (other than private pay-beds) occupied on the average in the hospital, the fund to be shared among the general practitioner staff as they may themselves determine.

It is expected that general practitioner hospitals should have an open staff.

(b) Part-time medical officers of convalescent homes or other types of hospital where no other rate is appropriate

£175 per annum per weekly "half-day" up to a maximum of £1,575 per annum, the "half-days" being assessed as in paragraph 5(a) above.

9. General Dental Practitioners employed at Hospitals

£150 per annum per weekly "half-day" up to a maximum of £1,350 per annum, the "half-days" being assessed as in paragraph 5(a) above.

Where there is no general dental practitioner on the staff of a general practitioner hospital the general dental practitioners of the district to be allowed at the discretion of the hospital management committee to have their patients admitted to the hospital where in-patient treatment is necessary. No contract need be entered into for this purpose as the dentist is remunerated by the executive council.

10. Determination of Salaries payable from July 5, 1948

(a) Specialists

The boards, in carrying out their review of existing staff, to ascertain the age of each specialist and the date on which he first accepted a staff appointment with full clinical responsibility. Assuming there has been no break in service, the salary payable from July 5, 1948, to be the salary which the officer would have been receiving on that date had the above system of remuneration been in operation since the date of his first appointment. In the case of specialists who were first appointed after age 32, the boards, in determining what their starting salaries would have been, to exercise their discretion as they would have exercised it had they been the appointing authority (see paragraph 1(a) (3) above).

(b) Senior Hospital Medical Officers

Boards or hospital management committees to have discretion to decide at which point in the salary scale for senior hospital medical officers existing staff should start, provided that the starting salary shall in no case be higher than that which the officer would receive were his position on the scale determined by age alone.

(c) Junior Hospital Medical Officers

Existing staff in the junior hospital medical officer grade who immediately before July 5, 1948, were receiving less than the minimum remuneration for the grade to start at the minimum of the salary scale; and those who were receiving more than the minimum to enter the scale at the salary they were receiving immediately before July 5, 1948, rounded off, at the discretion of the board or management committee, to the next incremental point in the new scale.

11. Incremental Dates

In the case of officers holding appointments at July 4, 1948, the incremental date to be July 5; in the case of new appointments or promotions, the date on which the new post was entered into.

12. Private Practice and Retention of Fees

See Appendix B.

13. Retiring Age

When an officer reaches age 65 his regular contract to come to an end, provided that

(a) the board may, with his consent, extend his contract of service (or offer a modified contract) for one year or any less period, and so from time to time until age 70, or

(b) the board may allow him an honorary contract as indicated in paragraph 5(c) above.

These ages to be reduced in respect of practitioners who are "mental health officers" under the Superannuation Regulations.

14. Tenure of Post

No fixed period of tenure to be specified in the contract of service of a specialist. Where a specialist felt that his appointment was being unfairly terminated by a board, to be entitled to send a full statement of the facts to the Minister, who would obtain the written views of the board concerned and place the case before a professional committee (consisting of representatives of the Ministry and representatives of the profession, under the chairmanship of the Chief Medical Officer) for their advice. The committee to have discretion to interview both parties if they thought fit. In the light of their advice the Minister to confirm the termination of services, or direct reinstatement, or arrange some third solution agreeable to the parties concerned, such as re-employment in a different post. This procedure to be completed before the board's decision to terminate the specialist's services was carried into effect.

15. Residential Emoluments

The above rates are non-residential. Where an officer is provided with residential or other emoluments by the hospital (i.e., the officer's main hospital), a reasonable inclusive charge to be fixed by the hospital management committee (or board of governors) for the accommodation or other emoluments (including meals), except that the charge for house officers to be a fixed rate of £100 per annum (see paragraph 3(c) above).

16. Leave

(a) Annual Holiday Leave

Officers in receipt of salaries of less than £1,000: at the rate of 4 weeks per annum (in addition to statutory and general national holidays or days in lieu).

Officers in receipt of salaries of £1,000 or more: at the rate of 6 weeks per annum (in addition to statutory and other general national holidays or days in lieu).

In the case of officers performing part-time services, leave entitlement to be based not on the actual salary but on the corresponding whole-time salary rate.

Absence for such purposes as attendance at court, etc., not to be taken into account for the purposes of annual leave.

The annual leave year to run from April 1 to March 31. New entrants to the service to be entitled to annual leave proportionate to the completed months of service during the year of entry, and thereafter on the normal scale.

(b) Compassionate leave, and any special leave other than "study" leave as defined in Appendix C

Leave without pay (normally not counting either for increment or pension) to be granted at the discretion of the board.

Leave with pay to be granted by the board with the approval of the Minister.

(c) Sick Leave

(1) Scale of Allowances

An officer absent from duty owing to illness, injury, or other disability to be entitled to receive an allowance in accordance with the following scale:

During the first year of service:

One month's full pay and (after completing four months' service) two months' half pay.

During the second year of service:

Two months' full pay and two months' half pay.

During the third year of service:

Three months' full pay and three months' half pay.

During the fourth to sixth years of service:

Four months' full pay and four months' half pay.

During the seventh to tenth years of service:

Five months' full pay and five months' half pay.

After completing ten years of service:

Six months' full pay and six months' half pay.

The board to have discretion to extend the application of the foregoing scale in an exceptional case.

(2) Calculation of Allowance

(a) The rate of allowance and the period for which it is to be paid in respect of any period of absence due to illness to be ascertained by deducting from the period of benefit appropriate to his service on the first day of his absence the aggregate of the periods of absence due to illness during the twelve months immediately preceding the first day of absence.

(b) For the purpose of ascertaining the appropriate period of benefit under Clause (1), all periods of service (without any break of twelve months) under any employing authority from whom hospitals have been transferred, any employing authority constituted under the National Health Service Act, or any local authority, in the Civil Service or the teaching service, or on national service (on call-up), or in any other service approved by the Minister for the purposes of Regulation 46(4) of the National Health Service (Superannuation) Regulations, 1947, to be aggregated, provided that if the officer was not in the service of any such authority during the twelve months immediately preceding the date on which his present employment commenced the service prior to that date to be disregarded.

(c) The allowance made to an officer during absence on sick leave when added to—

(i) the amount of sickness benefit receivable under the National Insurance Act, 1946,

(ii) the amount of injury benefit receivable under the National Insurance (Industrial Injuries) Act, 1946,

(iii) compensation payments under the Workmen's Compensation Acts where the right to compensation arises in respect of an accident sustained before July 5, 1948,

(iv) any element in compensation payments under the Employers' Liability Acts or under Common Law which is attributable to immediate loss of wages, and

(v) any amount received as a treatment allowance from the Ministry of Pensions,

not to exceed the officer's normal monthly salary, and the sick leave allowance to be restricted accordingly where necessary.

(d) The benefits to be taken into account under (c) (i)-(v) above to be those for the officer's own incapacity, including allowances for adult and child dependants.

(e) Where a married woman has exercised her option not to be insured under the National Insurance Act, no deduction to be made from her normal sick leave allowance during ordinary absence on sick leave, as she will not be receiving sickness benefit.

(f) For the purpose of this clause, twenty-six working days to be deemed to be equivalent to "one month."

(3) Conditions

(a) An officer who is prevented by his illness from reporting for duty to notify immediately the officer prescribed for this purpose by the employing authority. If his absence continues after the third day to submit forthwith a medical certificate as to the nature and probable duration of the illness. Thereafter medical certificates to be submitted at intervals of seven days or at such longer intervals as in any case may be decided by the employing authority. On his returning to duty, the officer to submit a medical certificate of fitness if required.

(b) An officer entering a hospital or similar institution to submit a medical certificate on entry and on discharge in substitution for periodical certificates.

(c) A case of a serious character, in which a period of sick leave on full pay in excess of the period of benefit under Clause (1) would, by relieving anxiety, materially assist a recovery of health, to receive special consideration by the employing authority.

(d) An allowance not to be paid in a case of accident due to active participation in sport as a profession nor in a case in

which contributory negligence is proved, unless the employing authority by resolution decide otherwise.

(e) A period of absence due to injury sustained by an officer in the actual discharge of his duty and without his own default not to be recorded for the purposes of this scheme.

(f) An officer who has received an allowance under this scheme in respect of a period of disability and recovers damages in respect of the disability to advise the employing authority forthwith, and the employing authority to be able, if they consider it equitable, to require the officer to refund a sum equal to the aggregate of the allowances paid to him during the period of disability or such part thereof as is deemed appropriate, but not exceeding the amount of the damages recovered, and, in that event, the period covered by the sum refunded not to be recorded for the purposes of this scheme.

(g) The employing authority to be able at any time to require an officer who is unable to perform his duties as a consequence of illness to submit to an examination by a medical practitioner nominated by the authority. Any expense incurred in connexion with such examination to be met by the authority.

(h) The provisions of this scheme to cease to apply to an officer on the termination of his employment whether by reason of permanent ill-health or infirmity of mind or body or by reason of age, but without prejudice to the right of an officer whose employment is terminated by reason of permanent ill-health or infirmity to receive the period of notice provided by his contract of service.

(i) If it is reported to the employing authority that an officer has failed to observe the conditions of this scheme or has been guilty of conduct prejudicial to his recovery and the authority is satisfied that there is substance in the report, the payment of the allowance to be suspended until the authority has made a decision thereon, provided that before making a decision the employing authority shall advise the officer of the terms of the report and shall afford him an opportunity of submitting his observations thereon and of appearing, or being represented, before the authority or its appropriate committee. If the employing authority decide that the officer has failed without reasonable excuse to observe the conditions of the scheme or has been guilty of conduct prejudicial to his recovery, then the officer to forfeit his right to any further payment of allowance in respect of that period of absence.

(4) Contact with a Case of Notifiable Disease

This scheme not to apply to an officer who is required to absent himself from duty following contact with a case of notifiable disease. In such a case the period of absence to be regarded as special leave with full pay.

17. Expenses

(a) General

Travelling, subsistence, and other expenses to be paid to meet actual disbursements of officers engaged in the service of the board and not to be regarded as a source of emolument or reckoned as such for purposes of pension.

In preparing claims officers to indicate adequately the nature of the expenses involved; claims to be submitted normally at intervals of not more than one month, and as soon as possible after the end of the period to which the claim relates.

(b) Travelling Expenses

Travelling expenses to be paid by the board for any journey in the board's service, provided that

(i) in the case of a *whole-time officer*, expenses incurred in travelling between his place of residence and the hospital where his principal duties lie not to be allowed except as indicated in (d) below.

(ii) in the case of a *part-time officer*, travelling between his private consulting-room or place of residence and any hospital where he is employed, whichever is the less, to be regarded as a journey in the board's service, provided that no expenses should be allowed for any such journey or part of such journey which would have been undertaken by the officer irrespective of his employment with the board.

(iii) expenses incurred in travelling from holiday leave to duty or vice versa not to be allowed unless the officer was recalled for special reasons.

(iv) taxi or cab fares to be payable only in cases of urgency or in other cases in which transport is reasonably required and an adequate public service is not available, but where these conditions are not fulfilled an officer using a taxi or cab to be entitled to claim the sum he would have been paid had he travelled by public service vehicle.

(v) an officer making an overnight journey by rail and engaging sleeping car accommodation to receive the cost, but any subsistence allowance payable to him for that night to be reduced by one-third.

Rates

(1) Except where a private car is used, the sum paid not to exceed the amount disbursed, e.g., if the practitioner is entitled to travel 1st class but in fact takes a 3rd class ticket he can only claim 3rd class fare.

(2) First class fares to whole-time officers with salaries of £760 and over, and part-time officers of corresponding status.

(c) Car allowances

Officers, whether whole-time or part-time, to be classified as "regular users" or "casual users" according to whether their annual official regular mileage is estimated to exceed 2,000 miles or not.

All regular users of motor-cars, of whatever horse-power, to be paid an annual allowance of £52 and 3½d. per mile. The annual allowance to be paid by quarterly instalments in advance. The mileage allowance to be paid monthly or quarterly. The annual allowance to continue during absences on annual leave or sick leave or whilst the car is out of use being repaired or overhauled, except that where any one period of non-user exceeds two months the sum of £4 6s. 8d. to be deducted for each complete month after the first (e.g., if a car is out of use for 3½ months, £8 13s. 4d. should be deducted from the allowance).

If at the end of the year it is found that an officer who has been treated as a regular user has not completed 2,000 miles, he should not be called upon to repay any part of the annual allowance. This does not preclude review and reclassification of any officer at any time where appropriate.

Casual users to receive no annual allowance, but to be paid 7½d. a mile for the first 3,120 miles a year and 3½d. a mile thereafter.

Where a "regular user" has contracts with more than one board which require him to make a claim to more than one board, the board with whom he has his main contract to be responsible for paying the annual allowance of £52 and for verifying from time to time from the other boards concerned that the officer is still a regular user, all the boards concerned to pay 3½d. a mile for actual mileage in the claims appropriate to them.

If an officer uses a private motor vehicle in circumstances where travel by a public service would be appropriate, a mileage allowance of 1½d. a mile to be payable irrespective of the type of vehicle.

Where other officers, or members of an employing authority, are conveyed in the same vehicle on the business of the National Health Service, and where fares by a public service would otherwise be payable, an allowance of ½d. a mile for each passenger to be payable.

The "allowance year" for the purpose of car allowance to be regarded as the year to March 31. In the first year in which an officer is authorized to use his car, a proportionate reduction of the 3,120 miles or adjustment of the annual allowance (as the case may be) to be made.

In this paragraph and paragraph (b) above, "public service" refers to railways, steamships, omnibuses, and tramways.

(d) Payment of Mileage Allowances to whole-time officers for journeys from home to the hospital where principal duties lie

Where a whole-time officer travels from his home to the main hospital either before and/or after an official journey, travels direct from his home to the place visited, or returns direct from that place to his home, mileage allowance to be payable for the whole distance travelled, subject to a maximum based on the return journey from the officer's main hospital to the place visited plus 20 miles.

Ordinary mileage allowance to be paid for the distance equal to the return journey between the officer's main hospital and the place visited. The additional twenty miles to be paid for as follows:

(i) If the officer is the holder of a current season ticket for travelling between his home and hospital—at the appropriate rate as detailed above.

(ii) If the officer is not a season-ticket holder—the appropriate rates less 1½d. a mile.

(e) Garage Expenses, Tolls and Ferries

An officer using his private motor-car for official travelling to be repaid any charges necessarily incurred for tolls and ferries, and, subject to the production of vouchers, for parking fees, and to be granted a flat rate allowance for garaging of 2s. a night if he is necessarily absent overnight in circumstances which entitle him to night subsistence allowance.

(f) Subsistence Allowances

(1) For officers in receipt of a salary of £760 per annum or over:

(i) An allowance not exceeding 30/- to be payable in respect of each night when the officer is necessarily absent from his home or main hospital on the business of the employing authority. The allowance to be reduced to 25/6 a night after the first seven nights at one place and to be further reduced after 28 nights if the stay extends beyond that period.

(ii) A night allowance to be deemed to cover a single period of absence of 24 hours.

(iii) A day allowance in respect of duties not involving a night's absence to be payable at the rate of 3/6 when an officer is necessarily absent from his home or main hospital for more than five hours but not more than eight hours, and at the rate of 8/4 when his absence exceeds eight hours.

(2) For officers in receipt of a salary of less than £760 per annum the following rates to be substituted for those in (1) above:

(i) A night allowance of 24/- (18/- after the first seven nights and up to a maximum of 28 nights in one place).

(ii) A day allowance of 2/6 for an absence of more than five hours and less than eight hours, and of 6/- for an absence exceeding eight hours.

(3) Payment of the allowances in (1) and (2) above to be subject to the following overriding provisos:

(a) day allowance not to be paid in respect of any period spent at a hospital as part of the normal duties of the officer concerned;

(b) night allowance not to be paid in respect of any period during which accommodation is provided without charge at a hospital; and

(c) day allowance not to be paid for any period during which subsistence is provided without charge at a hospital.

(4) Any meals taken by an officer at a hospital in the course of his normal duties to be charged for.

(g) Postage, etc.

Boards to reimburse any expenditure necessarily incurred by an officer on postage of telephone calls in the service of the board, through the periodical claim for travelling and subsistence.

(h) Conferences, Visiting, etc.

See Appendix C on "Study Leave, Conferences, etc."

18. Medical Examination on Appointment

The passing of a medical examination to be a condition of appointment of all officers within the scope of the National Health Service Superannuation Scheme, other than those who are transferred under the National Health Service Act. The fee for examination to be paid by the appointing authority.

The examining doctor to be asked to certify that the candidate is "free from any physical defect or disease which now impairs his capacity satisfactorily to undertake the duties of the post for which he is a candidate."

APPENDIX A

Clinical Specialists engaged in Teaching of Medical or Dental Students

1. *Whole-time Clinical Posts in Medical or Dental Schools*

As already announced by the Chancellor of the Exchequer, the rates of salary to which the University Grants Committee will have regard in making grants to universities are as follows (operating from April 1, 1949):

Professors: Within the range of £2,250 to £2,750.

Lecturers: £600 to a maximum within the range of £1,500 to £2,000 (or £2,500 for posts carrying special responsibility).

Readers: Within the range of £1,500 to £2,000 (or £2,500 for posts carrying special responsibility).

In addition, holders of these posts to hold an honorary (unpaid) appointment with the appropriate hospital board or boards, but to receive from the board payment of appropriate expenses, like other specialists, for hospital work. Also to be eligible for distinction awards, the additional remuneration being paid by the university or school and reimbursed to them by the board.

NOTE: Where exceptionally teachers (including part-time clinical professors or heads of university clinical departments) devote a large portion of their time to university work, to be paid the relevant proportion of the whole-time salary and distinction award by the same method as their whole-time colleagues.

2. *Part-time Clinical Teaching Posts*

Specialists performing teaching duties concomitantly with, or separately from, their clinical work to be remunerated by hospital boards like other specialists (including distinction awards and expenses) but in addition to be remunerated by the university or school in recognition of their teaching duties at a rate which appears to the university or school to be appropriate to those duties.

APPENDIX B

Private Practice and Retention of Fees

1. *Private Practice*

Whole-time officers not to be entitled to enter into arrangements with private patients under Section 5(2) of the Act to undertake private practice. The contract of a whole-time officer normally to provide that he may be called on to treat patients occupying Section 5 beds without additional remuneration. A part-time officer to be able to agree with a board that he will treat patients in Section 5 accommodation, in return for remuneration by the board, without charging the patients a private fee for his professional services.

2. *Payments for Professional Services not within the scope of the Hospital and Specialist Service*

N.B.—Before determining the entitlement of officers to retain payment for such services it has been necessary to consider, in the light of the Minister's statutory responsibilities under the Act, the wider question of payments from outside sources to hospitals and/or to members of hospital and medical staffs for the rendering of medical reports on patients who are receiving treatment, and or the examination, diagnosis and rendering of reports on persons referred to hospitals for these purposes only.

(a) All work of this kind to be divided into the following two categories:

Category I: work which may properly be regarded as within the scope of the hospital and specialist services provided under Section 3 of the Act; and

Category II: work which cannot be regarded as within the scope of the service but which may for convenience be done at hospitals or by members of hospital medical staff,

in accordance with the principles indicated and illustrated by reference to examples in the schedule attached to this appendix.

(b) Services which are in the first of these categories to be available free of charge to any person reasonably requiring them. Members of hospital medical staffs to be permitted to provide services which are in the second category at hospitals or elsewhere, where in the opinion of the board or committee their provision would not interfere with other hospital activities or with the proper discharge of the hospital duties of the officers

concerned; but services in this category to be available to persons requiring them (including Government Departments) only on payment of appropriate charges. Where hospital laboratory or radiological facilities are used, such charges represent two elements: (a) payment for professional services and (b) payment of hospital costs. Where hospital laboratory or radiological facilities are not required, no charge to be made for the use of hospital premises, payment being in respect of professional services only.

(c) Whether the practitioner concerned be a whole-time or a part-time officer, all charges in respect of professional services to be retained by him or remitted to him by the board or committee according as the money is received by the practitioner himself or (as is expected to be the more convenient course when the work is done in hospital) by the board or committee.

(d) Where hospital laboratory or radiological facilities are used, one-third of whatever payment is made for the item of service provided to be retained by or remitted to the board or committee, in respect of hospital costs.

SCHEDULE

Category I: Work which is within the scope of the Hospital and Specialist Services provided under Section 3 of the Act

(a) Examination and diagnosis and the furnishing of any report reasonably required in connexion therewith on a person referred to the hospital and specialist service for this purpose from a medical source for a second expert medical opinion is regarded as within the diagnostic service which it is the Minister's duty to provide. Examples are:

(i) examination and report on a person referred by a medical board of the Ministry of Pensions;

(ii) examination and report on a person referred under the National Insurance (Industrial Injuries) Act, 1946, by a regional medical officer of the Ministry of National Insurance or by a medical board or medical appeal tribunal for the purposes of that Act;

(iii) examination and report on a person referred by a medical referee appointed under the Workmen's Compensation Act, 1925, or under a scheme certified under Section 31 of that Act;

(iv) examination and report on a person referred by a medical recruiting board of the Ministry of Labour and National Service;

(v) examination and report on a person referred by a medical interviewing committee set up by the Ministry of Health to advise disablement resettlement officers of the Ministry of Labour and National Service on the working capacity of disabled persons;

(vi) examinations and reports on members of H.M. Forces or their families referred by medical officers of His Majesty's Forces who are treating them;

(vii) examinations and reports on patients referred (in connexion with treatment) by medical officers of education authorities or local health authorities. (N.B.—Reports required on employees by these authorities in their capacity as employers are included in category II(a)(iii) below.)

(b) X-ray examination of any person resorting to or referred to a mass radiography unit, and the furnishing of a report, if required, of the result of such examination, to be undertaken as part of the diagnostic service provided under Section 3 of the Act.

(c) Examinations and the furnishing of written reports on the mental or physical condition of offenders referred by courts under Sections 24 and 26 of the Criminal Justice Act, 1948, to be undertaken as part of the diagnostic service provided under Section 3 of the Act.

(d) The furnishing of a report to a patient who is under treatment at the time when the report is asked for, or with his consent to an interested third party, when the information required can be given without a special examination of the patient by reference to hospital records or from knowledge acquired in the course of attendance on the patient, is regarded as work which arises directly out of the provision of treatment under Part II of the Act. Such work is therefore within the scope of the hospital service. (N.B.—If a special examination of the patient is required, or the information

requested cannot be given readily from knowledge of the case, the work would fall within category II below.)

The following are examples of reports or certificates which it would normally be possible to provide without special examination of the patient:

(i) progress reports required by the Ministry of Pensions on a pensioner who is receiving hospital treatment;

(ii) reports required by employers (including Government Departments and local authorities) on employees who are receiving treatment (e.g., reports required in connexion with sick leave, superannuation or retirement questions, etc.). (Employees who are *not* receiving treatment are referred to under category II(a)(iii) below);

(iii) the "first" certificate of the cremation certificates required by relatives, where the deceased had been receiving hospital treatment. (N.B.—The "first" certificate would normally be given by the practitioner who had attended the patient in hospital, and would not involve a special examination. For the "second" certificate see (a)(x) of category II below.)

Category II: Work which is not within the scope of the Hospital and Specialist Services provided under Section 3 of the Act

(a) The following are examples of examinations, reports, etc., which, *when they do not fulfil any of the conditions referred to in paragraphs (a), (b), (c) and (d) in category I above*, are outside the scope of the hospital and specialist service:

(i) any report on a patient not under treatment at the time the report is asked for, or any report involving special examination of the patient other than those in (a), (b), (c) of category I;

(ii) x-ray examinations and reports for prospective emigrants;

(iii) examinations and reports on candidates for admission to training colleges for teachers;

(iv) examinations and reports required by employers (including Government Departments and local authorities) on employees or prospective employees. (N.B.—These would, therefore, normally be in category II where the employees or prospective employees were not receiving hospital treatment but were referred to hospitals or to members of hospital medical staffs specially for the purpose of examination and report.)

(v) examinations and reports on private citizens in connexion with legal actions;

(vi) examinations and reports for coroners;

(vii) examinations required for life insurance purposes;

(viii) certificates required under the Blind Persons' Act;

(ix) attendance at court hearings as medical witnesses;

(x) the "second" certificate of the cremation certificates required by relatives, where the deceased had been receiving hospital treatment. (N.B.—The "second" certificate would not be given by the practitioner who had been attending the patient. For the "first" certificate see (d)(iii) of category I.)

(b) Other work in this category includes:

(i) lectures given by members of hospital medical staffs to nurses, etc., or to the lay public;

(ii) services performed by members of hospital medical staffs for Government Departments as members of medical boards;

(iii) general practitioner services given by a hospital medical officer under Part IV of the Act to members of the hospital staff who are on his "list."

APPENDIX C

"Study" Leave, Conferences, etc.

"Study" leave (as defined in this appendix) to be granted in accordance with the following scheme. The scheme to be *provisional* and subject to reconsideration when experience has been gained of its operation.

General Rules

1. Study leave must be for the purposes of study (including search), teaching, examining, taking examinations, visiting clinics, or attending meetings or conferences of a wholly scientific or clinical character.

2. Where the purpose of study leave is to enable the officer to undertake work for which he will receive fees (e.g., teaching and examining) the leave should normally be without pay or expenses.

3. Where study leave is granted with pay the officer must not undertake any remunerative work without the special permission of the leave-granting authority.

4. Study leave cannot be claimed as a right.

5. Study leave can be added to periods of ordinary leave.

A. For short periods, i.e., not exceeding 7 days. (Normally such study leave would be granted for periods of 1 or 2 days, but in exceptional cases leave up to 7 days may be granted.)

1. Without pay or expenses—at the discretion of the hospital management committee or board of governors.

2. With pay but without expenses—at the discretion of the regional hospital board or board of governors, though authority may be delegated to a hospital management committee.

3. With pay and expenses—at the discretion of the regional hospital board or board of governors, subject to the rules governing the payment of expenses.

B. For periods exceeding 7 days but not exceeding 3 months (13 weeks).

1. Without pay or expenses—at the discretion of the regional hospital board or board of governors.

2. With pay but without expenses—at the discretion of the regional hospital board or board of governors.

(a) Any period of such study leave in excess of 3 weeks will involve a surrender of one day's ordinary leave for every additional day of study leave granted, e.g., an absence of 5 weeks will involve the surrender of one week's ordinary leave; a period of 9 weeks' leave will involve the surrender of 3 weeks' ordinary leave.

(b) For this purpose ordinary leave, not exceeding 3 weeks in all, may be carried forward from the immediately preceding leave year.

3. With pay and expenses—at the discretion of the regional hospital board or board of governors, subject to the foregoing and the rules governing the payment of expenses.

NOTE: (a) Not more than one period of leave under B 2 or 3 may be granted to one officer in any one leave year.

(b) Where an officer is employed by more than one board the leave must be approved by all the boards concerned.

C. For periods exceeding 3 months (13 weeks).

1. Without pay or expenses—at the discretion of the regional hospital board or board of governors.

2. With pay but without expenses } to be referred to

3. With pay and expenses } Ministry for decision.

II. Payment of Expenses

1. Where officers are teaching, examining, attending meetings or conferences or visiting clinics, etc., at the instruction of the regional hospital board or board of governors, no question of study leave arises, and expenses will be paid in the usual way and at the usual rates. Expenses in connexion with taking examinations (fees, travelling, subsistence) will not be paid.

2. Where officers have applied for study leave with pay for any of the normal reasons and the board is of opinion that the leave is of advantage to the service, the cost of travelling and/or subsistence may be defrayed wholly or in part at the usual rates.

3. While it is desired to give regional hospital boards and boards of governors the maximum amount of discretion in the granting of study leave, it is nevertheless necessary to obtain a fairly uniform policy in the matter of defraying expenses. For this purpose boards should limit their annual expenditure within the budgets already approved under both heads (i.e., 1 and 2) as follows:

Teaching hospitals—

(a) Undergraduate—£500-£1,200 according to size and circumstances.

(b) Postgraduate—up to £1,200 according to size and circumstances.

Regional hospital boards (including hospital management committees in the region)—

(a) Oxford and Cambridge	£1,200
(b) Newcastle Leeds Sheffield Liverpool Bristol Wales	}	£1,600
(c) Metropolitan regions Manchester Birmingham	}	£2,000

(a) Where the expenditure of a board for the year 1949-50 is likely to exceed the total stated, and it is not possible to meet the additional cost from "free moneys" at the disposal of the board, application should be made for permission to increase the amount allocated within the budget for these purposes.

(b) The foregoing estimates relate to expenditure on behalf of medical and dental officers.

(c) Regional hospital boards and boards of governors may combine to defray the total or part cost of an officer's travelling or other expenses.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Correspondence

Selfish Attitude

SIR,—As one of the "Bevan Boys" may I be permitted to express my view on the fight we have with the executive councils and the local medical committees, with whom the former work in consultation?

It is very regrettable that in our profession we should find members who do not practise the charitable virtue of "live and let live." Many of us have known to our sorrow the tyranny with which some local medical committees act, sometimes supported unnecessarily by executive councils in refusing an application from a doctor. In some instances there are doctors in the area with a number of patients on their lists exceeding the maximum number permitted by the Act, yet an executive council will support such selfish local medical committee to say that the area is sufficiently or over-doctored.

Unfortunately sometimes the applicant is ignorant of the reason for his being refused permission. The official intimation in my case was worded that my application had not been supported by the — executive council. This ignorance of the reason is a handicap for the doctor, for it makes an appeal difficult. In my case, accidentally, which was fortunate, I got to know the reason. The profession may be surprised to learn that it was chiefly the nightmare of the possibility of having to pay the dreaded basic salary to help set a new doctor—called an outsider—on his way.

It was with particular satisfaction, therefore, that one read in the *Supplement* of Feb. 19 (p. 85) that an authority like Dr. H. Guy Dain publicly administered a timely reproof to those selfish doctors. We read in the Press how doctors bemoan their long and arduous hours of work since July 5, 1948, but, let a new doctor attempt to go to such an area, suddenly these tired, opulent, ready-to-drop doctors will discover that they still have reserve energy to put up resistance against a newcomer. If this selfish attitude were allowed to assert itself unchecked it is sure to make co-operation and good relations impossible in our profession.

May I submit the following suggestions to the Association on behalf of the "Bevan Boy" doctors? (1) That the doctor

applying to an executive council be notified of the time, place, and date at which his application will be considered, so that he can avail himself, if he so desires, of the opportunity of learning at first hand how the decision was arrived at; alternatively, that the Medical Practices Committee be asked to inform such a doctor of the grounds of his being refused permission. This obviously will enable the doctor to know how to prepare his appeal. (2) That executive councils be required to give accurate and full facts as are available at the material time to any doctor making inquiries about an area.

It is desirable that the executive councils should be not only strictly impartial, but manifestly so.—I am, etc.,

Lancashire.

E. A. SHANU.

Graduated Capitation Fee

SIR,—The present suggested scheme of capitation fee for G.P.s does not take into consideration the principles that more experienced practitioners should be paid more than inexperienced practitioners, and that young active men can work longer hours or at a more rapid rate than the more elderly. I feel that insufficient attention has been paid to these problems and that sliding scales for different patients on the same doctor's list and mileage allowances to rural practitioners are but patches to prevent the newly launched Service from sinking.

The normal expectation of years in general practice is probably 40—e.g., from age 25 to 65. No man of 65 should be forced to work as hard after 40 years' general practice as he did at 25, but until a new system of payment is introduced economic circumstances will compel him to do so. This could be solved by the following method: (1) Have a basic capitation fee of, say, xs. (2) For every year after registration add 1/40 of xs. (3) Maintain the present limit of lists of 4,000 up to the age of 50 and thereafter scale it down to 2,000

Age of G.P.	Maximum No. on List	Capitation Fee in Shillings	Income in Shillings
25	4,000	x	4,000x
35	4,000	x + 10/40 x	5,000x
45	4,000	x + 20/40 x	6,000x
55	3,000	x + 30/40 x	5,250x
65	2,000	x + 40/40 x	4,000x

This would help to solve the problem of distribution of doctors. Young and vigorous doctors would be encouraged to work hard in the less popular areas and as they grow older would probably gravitate to the more attractive district where the increased capitation fee would balance the reduction in their lists. It is also seen from the table that the middle aged G.P. with maximum financial responsibilities, education of family, etc., is more amply rewarded for his experience while the elderly practitioner, by reducing his work to a bare and having a double capitation fee, can remain alive and have a reasonable chance of enjoying his retirement without prematurely sclerosed arteries.—I am, etc.,

Hove, Sussex.

A. MACFARLANE.

Whitley Council Machinery

SIR,—It appears that the local authority associations are still preventing the start of negotiations for members of the Public Health Service. If precise proposals have been put forward and accepted for a Medical Whitley Council, why cannot commence with consideration of salaries of regional hospital board medical officers, and the other public health salaries will follow?

Regional medical officers are committed to the Whitley machinery and to my knowledge no barriers exist to prevent these now being considered. Practically all the medical officers are ex-public-health officials, and it is of interest to note that appointment to regional hospital board posts was invariably at the bottom of the salary scale with no consideration for former placing on local authority scales.

In order to avoid the anomalous situation which has already arisen under the Whitley machinery in adjusting board management salaries to a higher level than regional board officials, prior to even considering the latter, it would appear only correct that, in considering public health salaries, you should start at the "top" and work down. It is cold comfort

to a medical officer transferred to these more responsible regional posts to anticipate that they shall be left behind—like the cat's tail!—I am, etc.,

Dundee.

G. C. TAYLOR.

Sliding Scale Unfair

SIR,—I fail to see the fairness of the suggestion for a sliding scale capitation fee. The doctor with 3,000 to 4,000 N.H.S. patients is probably a keen, hard-working, good, and popular doctor. He cannot be a lazy and bad doctor for so many patients to choose him. The doctor with only 1,000 N.H.S. patients is either a lazy and/or "bad" doctor, or working in an attractive neighbourhood where there are, in consequence, a large number of doctors. Exceptions of course there must be, such as very sparsely populated rural areas, etc.

On entering practice a number of us had to choose a relatively unattractive place where the financial side was good, although the work harder. I fail to see why now we should be paid relatively the same as those living in more attractive places. Most of us have only accepted our old patients on our N.H.S. lists, and to receive more for Mrs. Smith who was in our first 1,000 than Mrs. Jones who was in our fourth 1,000 seems ridiculous. The sliding scale would benefit and encourage the lazy doctor, with the present high taxation. By all means see that the doctor with 2,000 patients has a decent living wage, but see that the doctor with twice as many patients receives twice as much. Taxation will do the "unfair" adjusting!

Let us strive for initiative in our work, avoiding all of us being brought down to the same level; more the work, more the pay—otherwise it cannot be fair.—I am, etc.,

Ely, Cambs.

J. B. BAMFORD.

Cost of the N.H.S.

SIR,—Dr. Ffrangcon Roberts omits to mention in his article on "The Cost of the N.H.S." (*Journal*, Feb. 19, p. 293) certain important aspects of the problem. It must be seen in the light of total Government expenditure, and only then can we decide if the amount of money is being well spent. The Labour Party made promises in 1945 about extending essential social, educational, and health services. But one by one these promises have been excused and reduced in scope. Instead, it seems that it will take a quarter of a century to clear the housing lists, no new schools have been built in the London area, and no health centres are to be built within a reasonable time. This major strategy is of great importance to anyone interested in the purpose of his profession, and discussion about it in the *Journal* is not out of place. The budget these days is entirely one of peace and war arithmetic. The U.N. charter demands that a certain amount of military strength is required for peace. But the £760 million which we intend to spend on arms is far beyond our needs or even our ability. Mr. Bevan's £230 million plus £85 mill on is dwarfed by this sum, but has carried much more opposition.

One need only take an afternoon stroll in any one of our big cities to see how money is being wasted on unnecessary building, for instance. But we know how desperate are the folk on the housing lists and we know that their basic needs are being put behind the building of a new South Bank of the river and a £12 million aeroplane. No one quarrels with Dr. Roberts's attack on "luxury medicine," but most of your readers can give examples all over the country where a little more essential equipment would make all the difference to a competent service. Cuts in this sort of expenditure must be fought tooth and nail, and the *Journal* could do a great service in publishing details of fact contrasting wastage and needs wherever possible.—I am, etc.,

London, N.W.3.

C. F. HINGSTON.

Supplementary Ophthalmic Service

SIR,—The totalitarian pattern is unfolding—sentence before trial, mass punishment, the deprivation of the many in retaliation for the possible delinquencies of the few. The Minister is to reduce the Supplementary Ophthalmic Service fee from 1½ guineas to 25s. because an investigation carried out on 5% of practitioners in certain areas only revealed that an unspecified number of this 5% had earned more in consulting fees

than was thought seemly, and it had therefore been assumed that the time taken for the consultation had been less than half an hour.

No charge has been made that the work in any instance has been carelessly or indifferently carried out; no allegation has been made that inaccurate prescriptions have been given; and no statement has been made by patients expressing dissatisfaction with their reception, treatment, or the results of such treatment.

In the first place there was no expressed or implied contractual obligation that the actual consultation must be one of half an hour. That may have been in the Minister's mind but was not committed to paper. What was agreed was that the practitioner should give—in his own rooms, using his own equipment, and assisted by his own auxiliaries—to patients under the S.O.S. a consultation, for which the recognized private fee is 3 guineas, for 1½ guineas.

The Minister has not advocated a 'ca' canny policy in any other branch of medicine. In the hospital service, for example, whether in out-patient clinic or operating theatre, the practitioner, in order to implement the Service and to cope with the enormous demands made upon it, must work to capacity. No complaint is made by the authorities, for there he is paid on a sessional basis, and the more patients he deals with the better value he is giving to the Minister.

If too much is being paid to a few practitioners then it might be reasonable to suppose that either individual action could be taken or an arbitrary limit or ceiling could be imposed, as in the cases of dentists, general practice, domiciliary visits, and weekly sessions.

The sequence, however, is clear: the original estimate for ophthalmic services was £2 million; the revised estimate is £12½ million; the Treasury jibs; the Minister quakes; and the unorganized and inarticulate doctor pays.—I am, etc.,

Liverpool.

A. MCKIE REID.

Display of Hearing-aids

SIR,—As an otologist interested in hearing-aids since sitting at the feet of the late Dr. Phyllis Tookey Kerridge, I feel that all medical men will very strongly endorse the words of Mr. O. C. Leadbitter (*Supplement*, Feb. 12, p. 78). Surely it flavours of totalitarianism to forbid hearing-aids made by reputable firms from being demonstrated to patients attending hospital clinics? At these clinics it has been the practice to show and test patients only with those instruments which have been made by firms holding the certificate of ethical trustworthiness issued by the National Institute for the Deaf. Now the Government "Medresco" is available (at the moment in very small numbers, and with questionable efficiency of its mass-produced leads, earpieces, etc.) it seems only fair to patients to allow them the choice of this free aid (when they can get it) or a good proprietary aid where its sale is ethically correct and its financial liabilities fully explained and understood.

This Government should not refuse to allow comparison and competition with its own products, even though it persists in its refusal to allow any financial help towards the purchase of a proprietary article. Everyone will be pleased if the present Minister of Health "kills" the charlatan hearing-aid firms who have waxed rich on wicked advertisements and tricks, but there is no justice in classifying the reputable firms with the bad ones. A grave disservice is done both to the good firms and to the deaf public.

A point about the Medresco which may not be known to all is that this Government-sponsored aid—i.e., financed by public funds—is being sold abroad. The charge is less than that of good "proprietary" aids. In view of the enormous waiting-lists in this country it might be considered justifiable to expect the Government to allow reputable proprietary firms the foreign market, and so hasten the slow delivery of Medresco aids in this country.—I am, etc.,

London, W.1.

IAN G. ROBIN.

Dangerous Drugs Act: Restoration of Authority

The Home Office announces that the authorities granted by the Dangerous Drugs Regulations under the Dangerous Drugs Act, 1920, have been restored to Dr. John Joseph Coghlan.

Association Notices

B.M.A. LIBRARY

The normal Library hours will be resumed on April 4. Times of opening and closing will be: Monday to Friday 9.30 a.m. to 6 p.m., Saturday 9.30 a.m. to 12.30 p.m.

ELECTION OF MEMBERS OF COUNCIL

Notice is hereby given that nominations of candidates for election as members of Council, 1949-50, (a) by the following Branches, (b) by Public Health Service members, and (c) by women members must be forwarded in writing so as to reach me not later than Saturday, April 23, 1949.

Twenty-two Members by Branches in Great Britain and Northern Ireland

	No. of Members of Council to be Elected by Group
Group A.—North of England	1
Group B.—East Yorks; Yorkshire	1
Group C.—Yorkshire and Cheshire	2
Group D.—Lincolnshire	1
Group E.—Essex; Suffolk	1
Group F.—Berkshire, Bucks and Oxford; Birmingham; Staffordshire	1
Group G.—North Wales; Shropshire and Mid-Wales	1
Group H.—South Wales and Monmouthshire	1
Group I.—Metropolitan Counties	4
Group J.—Bath, Bristol and Somerset; Gloucestershire; Worcestershire and Herefordshire	1
Group K.—Dorset and West Hants; South-Western; Wiltshire	1
Group L.—Southern; Surrey	1
Group M.—Kent; Sussex	1
Group N.—Aberdeen; Dundee; Northern Counties of Scotland; Perth	1
Group O.—Edinburgh; Fife	1
Group P.—Glasgow and West of Scotland (Glasgow Division)	1
Group Q.—Border Counties; Glasgow and West of Scotland (Five County Divisions); Stirling	1
Group R.—Northern Ireland	1

Public Health Service Members

Two members of Council are nominated and elected by members of the Association employed in the Public Health Service as defined in By-law 1 (3). Candidates must be members of the Public Health Service as so defined.

One Woman Member

One woman member of Council is nominated and elected by women members of the Association.

Nominations

The nominations must be on the prescribed forms, copies of which can be obtained on application to me. A notice will be published by the Council in the *British Medical Journal* (Supplement) on May 7, 1949, of the candidates nominated. Where contests occur, voting papers will be issued on May 14, 1949, containing the names of all duly nominated candidates, from the Head Office, British Medical Association, Tavistock Square, London, W.C.1, to each member in the Group, or to the Public Health Service members, or to women members. A notice will be published by the Council in the *Supplement* of June 4, 1949, giving the results of the elections where there have been contests.

CHARLES HILL,
Secretary.

Meetings of Branches and Divisions

COVENTRY DIVISION

An Ordinary General Meeting of the Division was held on Feb. 8, with Dr. A. F. Wright in the chair. Dr. Clayton, M.O.H. for Coventry, introduced the subject "Health Centres" and outlined the developments of proposals. He was followed by Mr. D. Goldfinch, architect to the Birmingham Regional Hospital Board and consulting architect to the Birmingham Health Committee for Health Centres, who gave an interesting address on the planning of health centres. Slides were shown of different plans, and particular interest was evinced in plans which Mr. Goldfinch had prepared for health centres at Leeds and Birmingham.

The address was much appreciated, and an enthusiastic vote of thanks was accorded to Mr. Goldfinch on the proposal of Dr. C. F. Turner.

Diary of Central Meetings

MARCH

- 22 Tues. Subcommittee on Training of Assistants, 11.30 a.m.
- 22 Tues. Committee on the Postgraduate Education of General Practitioners, 2 p.m.
- 22 Tues. Joint Subcommittee on Association of General Practitioners with Hospitals, 2 p.m.
- 23 Wed. Council, 10 a.m.
- 24 Thurs. Ethical Rules Subcommittee, 12.15 p.m.
- 29 Tues. Special Representative Meeting, 10 a.m.
- 30 Wed. Special Representative Meeting, 10 a.m.

APRIL

- 4 Mon. Joint Committee of B.M.A. and National Veterinary Medical Association, 2 p.m.
- 6 Wed. Health Centre Committee, 2 p.m.
- 11 Mon. Armed Forces Committee, 2 p.m.
- 12 Tues. Proprietary Medicines Committee, 11 a.m.

Branch and Division Meetings to be Held

The following meetings have been arranged for consideration of (a) Report of Council on the Constitutional Position of the Association, and/or (b) Report of Council on Remuneration of General Practitioners in the National Health Service, and/or (c) Instruction of Representatives to Special Representative Meetings on March 29 and 30:

BLACKBURN DIVISION.—At Town Hall, Blackburn, Tuesday, March 22, 8.15 p.m.

CHelsea AND Fulham DIVISION.—At Fulham Town Hall, S.W., Friday, March 18, 8.30 p.m. for 8.45 p.m.

HASTINGS DIVISION.—At Ball Room, Castle Hotel, Wellington Square, Hastings, Sunday, March 20, 3 p.m. All medical practitioners in the area of the Division are invited.

HUDDESFIELD DIVISION.—At Huddersfield Royal Infirmary, Tuesday, March 22.

KINGSTON-ON-THAMES DIVISION.—At Public Assistance Offices, 35, Coombe Road, Kingston-on-Thames, Friday, March 18, 8 p.m. for 8.30 p.m.

MACCLESFIELD AND EAST CHESHIRE DIVISION.—At Macclesfield General Infirmary, Sunday, March 20, 12 noon.

NORTH MIDDLESEX DIVISION.—At Prince of Wales Hospital, Tottenham, N., Sunday, March 20, 3 p.m.

PORTSMOUTH DIVISION.—At Royal Beach Hotel, Southsea, Sunday, March 27, 6 p.m.

SALISBURY DIVISION.—At Old Manor, Salisbury, Sunday, March 20, 2.30 p.m.

SOUTH ESSEX DIVISION.—At Nurses' School, Oldchurch Hospital, Romford, Friday, March 18, 9 p.m.

WILLESDEN DIVISION.—At Willesden General Hospital, Harlesden Road, London, N.W., Tuesday, March 22, 9 p.m. All medical practitioners in the area of the Division are invited.

WINCHESTER DIVISION.—At County Hospital, Saturday, March 19, 3 p.m.

BATH, BRISTOL AND SOMERSET BRANCH.—At Bristol General Hospital, Guinea Street, Bristol, Wednesday, March 23, 8.30 p.m. Clinical meeting.

HENDON DIVISION.—At Hendon Hall Hotel, Wednesday, March 23. Dr. Helen Mackay: "Infant Feeding."

KENT BRANCH.—Tennyson-Smith Golf Cup: preliminary rounds must be played before May 31 and the final round before June 14. Competitors should send entries to their Divisional secretary by March 31 stating handicap and the day of the week most convenient for playing. The winner for each Division will compete in the final round.

MID-CHESHIRE DIVISION.—At Nurses' Pre-training School, Greenwood Street, Altrincham, Sunday, March 27, 3 p.m. Mr. A. Lawrence Abel: "Some Common Diseases of the Rectum and Anal Canal," with a cinematograph film of the abdomino-perineal operation for carcinoma of the rectum. All medical practitioners in the area of the Division are invited.

OXFORD DIVISION.—At Maternity Lecture Theatre, Radcliffe Infirmary, Oxford, Wednesday, March 23, 8.15 p.m. Address by the Rev. Leslie D. Weatherhead: "The Church and Medicine."

PORTSMOUTH DIVISION.—At Royal Beach Hotel, Southsea, Friday, March 25, 9 p.m. Annual Medical "Family Ball."

REIGATE DIVISION.—Golf competition at Tandridge Golf Club, Oxted, Thursday, April 28, 2 p.m. Those intending to play should notify Dr. Laing, Brambletye, Limpsfield, as soon as possible, giving telephone number.

WESTMINSTER AND HOLBORN DIVISION.—Joint meeting with Chelsea and Fulham and Kensington and Hammersmith Divisions at Postgraduate Medical School of the Royal Cancer Hospital, 24, Onslow Gardens, Fulham, S.W., Wednesday, March 23, 8.30 p.m. Professor A. Haddow: "Recent Progress in the Chemotherapy of Cancer." Open to all medical practitioners in the area of the Divisions.

WIGAN DIVISION.—At The Hollies, Wigan Lane, Wigan, Thursday, March 24, 8.15 p.m. Clinical meeting. Lecture by Mr. R. L. Hartley: "Breach Presentation and its Management." To be illustrated by a film.

LONDON SATURDAY MARCH 26 1949

THE PROPAGATION OF MOUSE TUMOURS BY MEANS OF DRIED TISSUE*

BY

W. E. GYE, M.D., F.R.C.P., F.R.S.

Director of the Imperial Cancer Research Fund

My first duty is to say that anything which is new in this lecture is the joint work of my colleagues, Dr. A. M. Begg, Dr. James Craigie, F.R.S., Miss Ida Mann, F.R.C.S., and myself. I have great pleasure in thanking them for their permission to mention researches for which we are all jointly responsible.

Most of us have heard the remark made that too much and too little is known about cancer. We know so much now about starting cancers by physical and chemical means and so much about the chemistry and biochemistry of cancer that the literature has become confused. But we do not yet know the cause of cancer, and of course we cannot, except in early favourable cases, cure it with certainty; and all this appears to be lamentable. Are we quite certain that we have studied carefully enough the work of the pioneers of cancer research—that we have not missed some clue which was clearly revealed forty or more years ago?

A brief survey of the early work of the Imperial Cancer Research Fund, which is representative of the researches of the earliest workers in experimental cancer research, is useful and rewarding.

The work which proved that the familiar animal tumours of mice, rats, and other small mammals are pathologically and biologically of the same nature as tumours of man may be passed over, though even now there are diehards in the ranks of the profession who apparently consider that no work counts unless done on man. Similarly the statistical work of Bashford, the study of the zoological distribution of cancer by Murray, and the variety of histological forms of the disease may for present purposes be neglected. Let us confine our attention for the moment to a consideration of the prime interests of the pioneers like Jensen, Bashford, Ehrlich, Leo Loeb, Borrel, and the many others who helped to lay the foundations of cancer research.

First of all Bashford clearly asked himself the question, What do I mean by the cause of cancer? He knew, like all the medical world of his time, that soot caused an excess of skin cancer in chimney-sweeps, and that coal-tar was responsible for much skin cancer. Indeed, in the famous memorandum on research which Bashford drew up for the Committee of the Fund one of the items specifically mentioned—this was in 1902—was the proposal to test whether Pott's observations on the carcinogenic properties of soot on man applied also to mice. For various reasons this was not carried out; it was left for Passey to do in 1920. As everybody knows, soot does start cancer in mice.

Bashford in his inquiries into the ethnological distribution drew attention to the occurrence of squamous epitheliomas of the abdominal skin of the natives of

India who wear the Kangri basket for warmth. He arrived at the obvious conclusions that long-continued application of heat leads to the occurrence of cancer and, more important still, to the obvious error of the Cohnheim hypothesis of the origin of cancer in cell rests, since, so far as he could determine, cancer of the abdominal skin was confined to those natives who wore the Kangri basket, and it is unlikely that these were the only men who had skin rests in the abdominal wall. He also wrote a great deal about betel-nut chewing and buccal cancer. But to Bashford, as to all the early workers in cancer, soot and tar and Kangri baskets were remote causes of the disease: they promote or precipitate cancer but play no further part.

The First Experimental Tumour

The first tumour produced experimentally was by the application of x rays to the root of the tail of the rat. This was done by Clunet, in France. It is of course only the deliberate application to a small animal of the same process which the pioneers of radium and x rays did unwittingly to themselves in the course of their professional work. Nobody could suppose that the tumour incidence was independent of the x rays; and nobody could believe that the x rays continued to act after the tumour had started or, in the case of the rat, could have any effect on the long succession of tumours in an unlimited series obtained by grafting small pieces in healthy rats. Bashford especially, and the contemporary workers incidentally, always distinguished sharply between what I have usually described as remote or adjuvant causes—chemical, physical, or parasitic—which lead to cancer and the intracellular continuing cause. This continuing cause is related to the pathological nature of cancer and is, in the sense in which we say that the tubercle bacillus is the cause of tuberculosis, the cause of cancer.

But at this point comes the real difficulty of the subject. Bashford and his colleagues could not find anything bacterial or chemical in tumour tissue that could start a new tumour. Any extract, freed of tumour cells, failed to cause the formation of a new tumour; likewise any tumour even partially dried was inactive. The tumours, in Bashford's sense, appeared to be causeless—that is, there was no continuing cause. Any procedure, however mild, which destroyed the life of the cancer cell destroyed all activity of the tumour after its inoculation into an appropriate animal.

Tumour-grafting

These findings corresponded beautifully with the findings of the process of grafting tumours. When a small fragment of a mouse tumour is placed under the skin of another mouse it was found—and this has been confirmed by workers all over the world—that the non-malignant tissues, the blood and lymph vessels and connective tissue

*An Imperial Cancer Research Fund Lecture delivered at the Royal College of Surgeons on March 22.

which constitute the stroma of a tumour, die rapidly; the central cells of the implanted tumour mass die more slowly, the peripheral cells of the graft alone surviving; a new stroma is formed by the new host, and this stroma nourishes the surviving malignant cells, which grow and multiply and form the daughter tumour. Bashford concluded, after a vast amount of work, that "cancer can only be transmitted experimentally by processes which allow of the continued growth of the tumour of one animal in other animals of the same species." He could find no evidence, nor could anybody else, which upset this conclusion, and therefore it appeared to him that it is not permissible to seek for the cause of cancer outside the life processes of the cells.

This naturally led Dr. Murray, Bashford's first assistant, to study cells, normal and malignant, with the greatest care to determine whether there is any difference which might account for the properties of malignant cells. Murray, who had worked for several years with Boveri, was naturally interested in the speculations which might usefully be summarized under the term "mutation," but he could find no evidence which justified any belief or confidence in such speculations. Thus the Fund's scientific staff arrived at the position in 1914 that cancers are, in a phrase familiar at that time, just "personal experiences" with no cause except possibly some intracellular distortion which in our then state of knowledge was undiscoverable. The situation, one of extreme pessimism, is illustrated by Ehrlich's reply to a young man who wished to do cancer research: "I have wasted 15 years of my life in cancer research. Until some fundamental discovery is made revealing the nature of life itself not a step forward will be made in our knowledge of cancer."

The First Chicken Sarcoma

In 1910 there came into the possession of Dr. Peyton Rous, of the Rockefeller Institute, a hen bearing a tumour which histologically was universally diagnosed as a spindle-cell sarcoma. This diagnosis was changed the following year—not by Rous—when Rous proved that cell-free extracts contained an agent which was capable of starting the tumour afresh in appropriate chickens. Here was an entirely new fact. All the laborious efforts of workers to do just this with filtrates of mouse, rat, and guinea-pig tumours had failed. The first chicken sarcoma examined by Rous succeeded, and pathologists and surgeons interested in cancer at once denied the malignant nature of the chicken tumours. The agent which multiplies with the growth of the tumour is now recognized as a virus. Electron-microscope photographs have been taken, and the sizes revealed by such photographs are in fair harmony with sizes deduced from experiments with collodion filters. The virus is more or less spherical and occurs in clumps in the tumour cells.

Now we know of several hundred filterable tumours of the domestic hen. They are of different structures: some, but very few, are simple spindle-cell tumours resembling the Rous sarcoma; others include chondromas, osteochondromas, fibrosarcomas, myxosarcomas, muscle-cell tumours, and so on.

There is one strange character possessed by all these tumours which must be mentioned. When a tumour is propagated by grafting with living cells it is to be expected that the daughter tumour, if derived entirely by growth and multiplication of the implanted malignant cells, would be of the same histological type as the original tumour. With the propagation of tumours by means of cell-free filtrates the new tumour is literally new; it is made up of the host's cells which have been infected by the inoculated virus. But it has universally been found that the inoculated

virus can start a tumour only of the kind from which it is derived. Thus a spindle-cell tumour always gives rise to a spindle-cell tumour, an endothelioma to an endothelioma, and so on. The virus is so specialized in its effects that it represents in itself all the qualities and properties of the cell from which it is derived. Nevertheless, an immune serum made by injecting virus from one tumour will neutralize the viruses from other types of tumour, which indicates a common antigenic element.

Filterable and Non-filterable Tumours

It will clearly be seen from this brief account of various sorts of tumours that there is a fundamental difference of a strange kind between filterable virus tumours and the non-filterable mouse tumours; the tumours of chickens, the adenocarcinoma of the frog, the Shope papilloma of the rabbit, and now the mammary cancers of inbred mice all have a virus as a continuing cause, whilst the vast majority of tumours of the small mammals, and presumably of man, apparently have no continuing cause.

If one dwells exclusively on the non-filterable tumours one is driven to theorize and even to accept almost impossible explanations of cancer and to dismiss the tumours from which a virus can be obtained as a disease *sui generis*. But this cannot be done convincingly; for the filterable tumours of chickens possess all the properties which everybody acknowledges as being those of cancer and none other except this one property of transmissibility with filtrates and dried tissue. Manifestly if mouse tumours which have hitherto resisted such cell-free propagation could be so propagated, and especially if newer methods had to be worked out to achieve this success, the apparent fundamental dichotomy of tumours would disappear and we should then be able to include such tumours among the filterable tumours without any strain in our minds. We should be able to regard tumours in general as being of one sort, as collections of cells carrying an active virus as the intrinsic cause.

My colleagues and I have considered cancer literature very carefully and have come to the conclusion that two facts discovered long ago are possibly the key to the general problem of cancer causation. I shall now deal with these in turn.

Transformation of Stroma of Epithelial Tumours

The first fact is the occurrence of sarcomatous transformation of the stroma of epithelial tumours. This was observed independently by Bashford and Ehrlich, and was worked out by the late Professor Haaland in our laboratories and by the late Dr. Apolant in Ehrlich's laboratory in Frankfurt. It was shown by histological methods that the spindle-cell tumour arises from normal stromal connective-tissue cells and is not, as sometimes happens in animal and human tumours, an alteration in shape and appearance of the epithelial malignant cells. In other words, the epithelial cells influence the normal well-behaved connective-tissue cells, which then assume malignant properties. Either something passes from the malignant cell to the normal cell, or the normal cell just imitates the neighbouring malignant epithelial cell. Can we assume that a virus passes and becomes gradually adapted to the normal cell? This becomes more probable when we consider the frequency of this occurrence in the inbred strains of mice.

It is now common knowledge that by brother-sister mating of selected mice it is possible to get homozygous strains of mice in which 90% or even more of the females develop mammary cancer. When one of these tumours is transplanted in the normal stock of the same strain the graft always takes; transplantation is easy and certain. It

was observed by Dr. Gorer at the Lister Institute in 1937 that transplants of mammary cancers in inbred strains show sarcomatous transformation very readily—in about 70%—whereas in ordinary non-inbred mice it is an infrequent occurrence. We have considered this fact very carefully and have adopted the working hypothesis that the process of inbreeding for cancer is quite different from inbreeding for unit characters such as coat colour; these are incidental to such breeding. We have looked upon the process as a means of selecting the most active or virulent strain of virus, which has now been shown in these tumours. Certainly unless the tumour incidence is carefully watched and a main cancer line is kept the incidence of tumours falls from 90% to 40 or even 20%; and this fall is independent of the brother-sister mating. It is due, as W. S. Murray has proved, to a change in what he calls the "tumour inciter"—i.e., the virus—which presumably loses some of its pathogenicity.

Effect of Cold

The second fact is one which was discovered by Ehrlich and published in 1907. It is this: that cancers, both sarcomas and carcinomas, can be kept at the low temperature of -10°C . for as long as two years, and when transplanted again give rise to the same tumour. With the exception of my late colleague Dr. W. Cramer, all who have repeated the experiment have concluded that the cancer cells have survived this prolonged freezing. Cramer was more cautious, and gave very cogent reasons for his doubts. It must be remembered that cells which are kept at a temperature of -10°C . are not just frozen *en bloc*. This temperature is cold indeed, but its action on cells is disintegrative. Water is turned to ice, but the salts in the cells do not come out with the water until a temperature of -21.1°C . is reached. Thus the internal medium of the cells is a strong solution—15 to 20%—of brine. The cells are "cured" as bacon is "cured"; nevertheless this experience of Ehrlich's has been uniformly, except by Cramer, interpreted as a marvellous example of the resistance of cancer cells to adverse conditions.

Further, it is quite well known that malignant cells which are kept at ice-box temperature, around 0°C ., lose their capacity to start tumours again in a few days' time. The truth is, of course, that the failure of the early workers to find a continuing cause in tumours bit so deeply into the mind that there was no inclination to look at facts dispassionately. Moreover, the experience of histopathologists of the nineteenth century, especially that of Ribbert, had an enormous influence on the thinking of experimental workers.

Reinvestigation

We have reinvestigated the whole subject. The first step was a comparison of the effects of cold on normal tissues. The method lay readily to hand. Several years ago Miss Mann investigated the growth of embryonic tissue in inbred mice. It was already known that embryonic tissue of laboratory stock mice survives for some days in mice which are not inbred; the embryo tissue and the tissues of recipient mice are different antigenically, and those reactions which are set up against foreign proteins come into play very soon and lead to the death and destruction of the implanted embryonic tissue. In homozygous mice in which the tissues are identical chemically no such reactions occur; the embryonic tissue is not resisted, and consequently it grows to form an embryoma which persists practically indefinitely. The cells are at home, and the recipient mice accept them readily. Consequently it is an easy matter to determine whether cold destroys normal embryonic tissue and to prove the effects by simple grafting of such treated tissues into the same homozygous strain.

After prolonged and repeated experiments Miss Mann has proved quite conclusively that normal embryonic tissue is killed after less than an hour's exposure to a temperature of -79°C ., whereas malignant tissues survive such a temperature for a period of more than one year—it may be, so far as we know, indefinitely.

The second stage in the investigation was an examination microscopically of grafts of malignant tissue that had been transplanted into a number of mice which were killed at various intervals from hours to days. This form of investigation is designed to find what happens to the graft, to see whether the tumour which forms after inoculation of refrigerated tumour tissue into appropriate animals is derived from surviving cells—i.e., a continuation of the tumour by growth and division of the original cells—or whether it is a new tumour of the recipient mouse's own tissues. This form of experiment I had already carried out 20 years ago, and the same results were noted in this repetition. With tumours which have been subjected to a temperature of -79°C . the whole mass of implanted tissue shows no normal cells; they stain yellow with picric acid after a sojourn of two days in a mouse, or a structureless pink with eosin; the cells and nuclei are structureless; the mass of necrotic tumour tissue becomes surrounded by reaction tissue, becomes shrunken, and eventually disappears.

With sarcomas the new tumour forms in the capsule of tissue which is derived from the host. Occasionally when refrigeration is very short, a matter of minutes, an obvious malignant cell, best recognized when carcinomas are used, is found in the mass, and from this cell a daughter tumour arises by growth and multiplication of such a surviving cell. This observation, made during the time Cramer was studying the effects of refrigeration, led to a sense of insecurity, especially to one who was Bashford's pupil. The final conclusion we have reached from these studies is that malignant cells, like embryonic cells, are readily killed by extreme cold, but that dead malignant cells are nevertheless capable of starting a new, strictly new, tumour in virtue of the intrinsic virus which they contain. Comparisons with normal tissues and histological studies, however, do not give the certitude which is necessary when the issues are as important as they are in this work.

Tumour Transmission

While some of these researches were in progress Dr. Craigie, with Dr. Begg, studied the effects of extreme division of the tumour tissue and of the action of various diluents on the finely divided tumour tissue.

Normally in cancer laboratories tumour tissue is broken up or emulsified by using fine scissors to make a mince which will pass easily through a needle of very wide bore. This was not good enough for the quantitative work needed in these researches. Dr. Craigie therefore designed and had made in the Fund's workshop a new and improved tissue-mincer by which suspensions of cells in diluents such as distilled water, glucose solutions, glycerin, saline, etc., could be obtained sufficiently finely divided to pass through the finest bore of needle (26 gauge). The results obtained by injection of such fine emulsions of frozen tissue cannot be interpreted simply as being the consequence of survival of cells on freezing. For example, many diluents such as distilled water, 40% glycerin, and 40% glucose which one would expect to be lethal to cells do not prevent tumour formation, and, contrariwise, diluents such as peptone which would not be expected to kill cells on freezing do inhibit tumour growth. The whole matter is difficult and complicated, and is an obvious subject for more research. But it can be stated quite definitely that

long-continued exposure to a low temperature, as long as one year, does not affect the capacity of tumour tissue to start tumours again when injected into appropriate animals. Indeed, since we know from histology that all or nearly all cells—we can never exclude the possibility of one cell escaping microscopical attention—are killed by keeping at a temperature of -79°C ., and also that tumours kept a year are often more active than corresponding fresh tumour tissue, it is in the highest degree improbable that the tumours which form after inoculation of refrigerated tissue are a mere grafting of living cells. They are much more likely to be strictly new tumours brought about by the infective action of the intracellular cause which has hitherto escaped attention.

But on this slightly uncertain note we could not end. We realized, none more definitely, that it was necessary to transmit a tumour with tissue which had been completely dried. To this we therefore turned our attention. During the past 14 years most of the mouse and rat tumours have been dried by one method or another and no success has been obtained in any single experiment. A new apparatus for drying small amounts of tissue, seldom more than a gramme, was designed by Dr. Craigie and made for us by the Glass Printers Company of Harrow. A description of it is in the scientific press. The essential improvement in this apparatus is the absence of any constriction in the path that water vapour must follow and in the power of the "backing pump." With this apparatus we have succeeded in propagating three mouse sarcomas with perfectly dry tissue. The tumours are as follows:

1. A sarcoma which was started in the inbred mice known as C57 Black by injecting about 1 mg. of the pure chemical compound methylcholanthrene. The chemical was injected in 1941; in the early months of 1942 tumours formed. From one of them transplants were made into six normal C57 mice. The tissue inoculated grew in all the mice; from one, a further transplant was made. This process of perpetuating the tumour has now been carried on for seven years; the serial number of tumour is now nearly 200. Thus about 200 transmissions by grafting have been carried out, and during these years the tumour was dried and filtered again and again in attempts to propagate the tumour acellularity. All these attempts failed. Even tissues which were deliberately used before drying was complete and whilst the tissue was still damp failed to give rise to tumours.

2. A sarcoma of the inbred strain R3 which arose by infection of the connective-tissue stroma of a carcinoma. This is the most malignant of our transplantable tumours. It was separated from the carcinoma by rapid transfers by Dr. Ludford. It is made up of spindle cells and multinucleated giant cells; around the tumour there is usually a glairy fluid in which disintegrated cells can usually be found.

3. A sarcoma of the homozygous strain C3H. This again arose during the transplantation of a sporadic mammary carcinoma and was also purified by early transplantation of the carcinoma by Dr. Ludford.

Experimental Results

It is best to take the methylcholanthrene tumour first. It is the least malignant of the three but has been tested most often for transmissibility with cell-free extracts during the past seven years. Even now, using our most efficient drying apparatus, we have so far been unable to obtain active dry material of a tumour fresh from a mouse. To obtain active dry tissue it has been necessary to subject the tissue to the low temperature of -79°C . for five to eight weeks before drying. Even then, as the following table shows, it is not yet possible to obtain regularly active material.

It will be observed that in one experiment of this group only one tumour developed in eight mice, and this did not appear until the 24th day after inoculation. This experience has been found in other experiments. In others again, in which variations have been made in experimental methods,

the results were entirely negative. But as a summary we can affirm quite definitely that it is possible to obtain perfectly dry tumour tissue which will start the tumour afresh.

Expt.	Tumour	Time of Freezing at -79°C .	No. of Mice	No. of Tumours	Time of Appearance
406	C48 in C57 black	35 days	7	6	17 days
G13B	" " "	52 "	18	13	16-31 "
434	" " "	53 "	12	9	16 "
G26	" " "	105 "	8	1	24 "

It is a matter of some importance to propagate tumours in series with dry tissue. This has been started, but owing to the time needed for refrigeration before drying we have succeeded so far only in carrying through two generations; the third generation has only just been tested.

When we come to the much more malignant R3 and C3H sporadic tumours we find that both of these are capable of yielding active dry tissue when fresh tumour is dried. In two successive experiments with the R3 tumour we obtained from dry tissue of fresh tumour (derived originally from frozen material) eight tumours out of ten mice inoculated, tumours appearing 14 to 33 days later; and one tumour out of six mice, the tumour appearing in 14 days. In an experiment with the C3H strain, fresh tumour tissue dried under the optimum conditions attained so far gave six tumours in 12 inoculations, the tumours appearing in 15 to 27 days.

Even with these very malignant tumours of the R3 and C3H strains of mice it has been found that preliminary freezing is helpful. For example, in three successive experiments with the R3 tumour it was found that tissue which had been frozen 28 days gave six tumours in six mice inoculated, the tumours being observed at 11 days; tissue frozen 34 days and then dried gave 10 tumours in 10 inoculated mice, the tumours being palpable in eight days and large on the 13th day; and tissue frozen 75 days, dried, and the dry powdered tissue then inoculated into six mice gave six tumours in 11 days.

We have no proof of numerous possibilities which may happen to tissue which is refrigerated for long periods of time. It is possible that low temperatures denature an inhibitory protein, thus liberating virus and making it available even after drying. The only merit this speculation possesses is that in the filterable tumours of chickens it is possible under favourable circumstances to demonstrate the presence of an inhibitory substance. This has been particularly well shown by J. B. Murphy, of the Rockefeller Institute. We have no complete proof of any of our numerous private speculations on this point; we are content merely to state what is the fact. It is possible that with more perfect methods these difficulties will vanish and speculation will become unnecessary.

At present the only conclusion from the whole work which is of vital and abiding interest is that it is no longer justifiable to put the normally easily filterable tumours of chickens in a separate class and turn a rather scornful eye on them. This work has now brought tumours of mice—average tumours found in all well-equipped cancer laboratories—into the same class. They have, as was to be expected, a continuing cause, and, since the continuing cause of chicken sarcoma is a virus, probably it is viral in nature. We have not yet transmitted other mammalian tumours with dried tissues, nor indeed have we seriously attempted to do so; but we think we are justified in making the contention that the negative results of the past are merely negative and have the value only of negative experiment which is the result of imperfect technique. If the pioneers of cancer research, men like Jensen, Ehrlich

Bashford, and many others, had by chance succeeded in transmitting mouse tumours with perfectly dry tissue the situation in cancer-thinking would have been entirely different, and we should have been spared the confused speculations which now dominate cancer research.

There is one final point I wish to refer to—namely, whether viruses are of intrinsic or extrinsic origin. It is now almost the custom to consider the viruses of the filterable tumours as particles of chemical nature made by the infected cells. Indeed, this mode of thinking has now gone so far that the word "virus" has been objected to, though the grounds of objection do not appear to us to be valid. We are not wedded to a word; they may be called anything so far as we are concerned. It is more important to discover perfect ways of getting and handling them, to find out how they act, and to learn if possible how to control them. The problem of discovering the nature of viruses, whether made by cells or of extrinsic origin, is not confined to cancer viruses; it is a part of the general virus problem. There was a time when the bacteriophage was allied to cancer viruses as being a product of the bacterial cell, but that has now passed. The argument concerning biogenesis or abiogenesis of the Pasteur-Bastian period does not interest us, and its repetition now, with viruses taking the place of bacteria, seems to be sterile from the beginning.

Conclusion

The experimental evidence described above points to the conclusion that cancer has a continuing cause and that this, in mammals as in birds, is a virus.

LONG-TERM CARDIAC OBSERVATION OF CHILDREN

BY

R. KEMBALL PRICE, M.D., M.R.C.P.

(From the Cardiac Department, Royal Sussex County Hospital)

The proper assessment of cardiac signs found in a child is of considerable importance to its future. Many children in whom murmurs are heard have no disability, and the greatest danger is that their activities may be restricted and the seeds sown for the development of cardiac neurosis. In rheumatic heart disease a normal school life with games can often be allowed when the disease is inactive, even when valve lesions are known to be present. With the advance of cardiac surgery it is desirable that cases for which it may be necessary should be diagnosed as early and as accurately as possible and submitted for operation at the most suitable time.

The choice of a career which will not need to be changed on account of a disability that is likely to increase should be made before leaving school. It is difficult for one who has done nothing but manual labour to find a sedentary occupation in middle life, and this can be avoided by choosing suitable employment from the start. For these and other reasons there are great advantages in children with cardiac abnormalities being under regular observation at cardiological centres. There are many questions in cardiology which can be settled only by watching patients over a period of years. J. W. Brown (1939) has done much in this way to increase our knowledge of the natural history of congenital heart disease. By similar observation much may be added to our understanding of the course of rheumatic heart disease.

What happens in the years between the acute or sub-acute phase seen in the child and the young woman who is discovered to have mitral stenosis during pregnancy?

Is the development of the stenosis due to recurrent activity of the rheumatic infection, or, once started, does the narrowing progress steadily without evidence of further activity, or are both factors at work? What happens to the innocent murmurs so common in childhood? At what age do they disappear?

A Cardiac Clinic for Children

With these considerations in mind a children's cardiac clinic was started eighteen months ago, and a report of the first 200 cases is here given. Apart from its intrinsic interest, the appreciation of doctors, parents, and, not least, the children themselves is encouraging and makes the clinic a happy one. As an investigation of this kind requires observation over a period of many years it is desirable that the observer should start while young enough to allow continuity of at least twenty years. It is with the idea of encouraging others who may be interested to take up such work that this preliminary report is presented.

The work has been made possible by the willing co-operation of the local school medical authorities. An afternoon is set aside and four to six children are seen by appointment each week. The number attending on each occasion is kept small so that full and unhurried examination may be made. It also means that no one is kept waiting very long—a point which makes them more willing to come again when asked.

Children showing any cardiac abnormality whatsoever at routine school examinations are placed on a list and referred to the clinic. The net is purposely cast wide to include all conditions, ranging from innocent murmurs to serious heart disease. A careful history is taken, followed by clinical examination, electrocardiograms, and cardioscopy. Twelve-lead electrocardiograms consisting of V1-6 and augmented unipolar limb leads in addition to the standard leads are now being taken in all cases, and routine phonocardiograms are to be started shortly.

If the child is very nervous or fretful the blood-pressure reading, electrocardiography, and cardioscopy may be postponed until the next attendance, as it is considered important that its memory of the visit to the cardiac department shall not be unhappy. This greatly facilitates subsequent examination. Teleradiographs are taken in cases showing abnormality on screening. Blood counts and sedimentation rates are done in certain cases. A report is sent to the school medical authorities and to the patient's own doctor. Arrangements are made for re-examination after an interval of six or twelve months or sometimes earlier.

Report of First 200 Cases

The distribution of the 200 cases is shown in Table I. There were 96 boys and 104 girls. It will be seen that approximately 40% had, or were suspected of having,

TABLE I.—Distribution of Cases

Cases with Organic Heart Disease.

I. Congenital malformations (44):	
Fallot group (one with congenital heart-block)	7
Pulmonary stenosis	10
Ventricular septal defect	6
Patent ductus arteriosus	3
Coarctation of aorta	3
Atrial septal defect	3
Congenital heart-block	1
Observation—congenital heart disease	11
II. Rheumatic Heart Disease (37):	
Mitral stenosis (six with active disease)	21
Mitral stenosis and aortic incompetence	2
Observation—mitral valvular disease or cardiac enlargement	14
Cases without Organic Heart Disease (119):	
Innocent murmurs	56
Physiological third heart sound	5
Decreased sternum	1
Splitting of first heart sound	1
Anaemia	1
Displacement (scoliosis, 1; pulmonary fibrosis, 1)	2
Irregularities (sinus arrhythmia, 1; extrasystoles, 2)	3
No abnormality detected	10

organic heart disease. The remaining 60% are classified under the most prominent feature discovered. Innocent murmurs provide the majority. Many of those with murmurs also showed a third heart sound, but unless the triple rhythm was the only feature cases were not classified under it. Those with organic lesions are divided into congenital malformations and rheumatic heart disease, the former showing a slight predominance.

The "observation" group is useful and may well prove the most important over a long period. In it are placed cases that cannot be passed as normal at the first examination, but in which the signs are so slight that a definite diagnosis of heart disease is not justified. It will be of great interest to see which way these cases develop—whether the suspected abnormalities disappear, or whether a clear pattern of heart disease emerges. The group is also used for cases of congenital heart disease in which the nature of the lesion is obscure. With increasing experience more accurate diagnosis becomes possible and fewer have to be placed in this group, but there will always be a number in which a complete diagnosis cannot be made during life.

CASES WITH HEART DISEASE CONGENITAL MALFORMATIONS

Fallot Group.—Ages ranged from 5 to 16 years. With one exception these seven cases had all been diagnosed as having heart disease in infancy; development was poor and disability varied from moderate to considerable. All showed varying degrees of enlargement on cardioscopy, but the "cœur en sabot" which has been described as characteristic of this condition was seen only twice. Blood pressure tended to be low. The expectation that all such cases will show steadily increasing disability is not supported by follow-up studies. Of six cases, four showed improvement during the first year of observation, one remained the same, and one showed increased disability and was referred for operative treatment. The improvement in two was striking: one who could walk only a few yards when first seen can walk a mile; another who used to squat had not done so for six months and was walking well. Bearing in mind the limited improvement that can be expected from a successful operation, it is desirable that surgical treatment should be reserved for those whose disability is very great and in whom progressive deterioration is occurring.

Pulmonary Stenosis.—In the majority of these ten cases the heart lesion was discovered at examination for some other purpose, and in half of them remained unnoticed until the first routine school examination at the age of 5. Disability was generally slight and physical development fair. Because of the impressively loud murmur there is a tendency to restrict the activities of such children far more than is necessary. Most of these are now playing games happily without symptoms.

Ventricular Septal Defect.—Like the preceding group these children's murmurs were usually discovered accidentally and all but one had been forbidden to play games. Of the six children in this group the only one to complain of shortness of breath was later found to have a mid-diastolic murmur and is really a case of mitral stenosis. Electrocardiograms were normal apart from slight prolongation of the P-R interval in one, and prominent S waves in lead I in two. Screening revealed slight right-sided enlargement in three; the rest were normal. All are now living an ordinary school life.

Patent Ductus Arteriosus.—One of the three cases in this series—a boy aged 9—has no symptoms. He is being watched but not operated upon meantime, as I agree with the view expressed by Benn (1947) that in symptomless cases the risk of operation may be greater than the risk of

bacterial endocarditis or heart failure. The other two cases showed unusual features and are here briefly described.

One of these two patients was a girl aged 13½, the condition of whose heart was first noticed during pneumonia at the age of 4. Subsequently she suffered from recurrent respiratory infections and was often away from school for long periods. At one time she was in hospital for a year, and later attended school for half-days only. She had an over-anxious mother and there is some doubt if all this care was really necessary. Her general condition was poor, and in addition to signs of pulmonary fibrosis there was considerable cardiac enlargement with the typical machinery murmur below the left clavicle. Blood pressure was 160/30 at rest and 170/0 at exercise. In view of her poor general condition and the size of her heart it was thought that there might be some other heart condition as well as the patent ductus. She was therefore seen by Sir John Parkinson, who agreed that operation was advisable, as the prognosis without it was bad and might bring great improvement. She was operated upon at the London Hospital by Mr. Vernon Thompson, who found a short and very wide ductus (8 mm. in length and 11 mm. diameter), which was tied. She made an uninterrupted recovery, and her general condition has since improved greatly. Six months after operation a systolic murmur developed in pulmonary area and has persisted unchanged (six months later). Such murmurs are sometimes heard after operation for patent ductus arteriosus, and no satisfactory explanation for them has yet been given. They are not always evidence of recanalization.

The other patient, a girl, had had a patent ductus tied at age of 7 on account of poor physical development. She made a satisfactory recovery and was in excellent health for a year after operation. She then began to get attacks of pain across the sternum, associated with severe dyspnoea and cyanosis. They had no relation to exertion or food, but were associated with a slight rise of temperature. The attacks became more frequent, she lost weight, and her general condition deteriorated. The heart sounds remained closed and electrocardiogram and x-ray film were normal. Blood cultures were negative and there was no evidence of embolism. The attacks were puzzling, but they were considered cardiac in origin and it was thought that bacterial infection must have occurred, possibly in the stump of the ductus. After a few weeks course of penicillin her general condition improved greatly. She has gained weight, and the attacks, though still occurring, are milder and much less frequent.

Coarctation of the Aorta.—It is probable that this condition is very much commoner than has been thought, when it becomes a routine to palpate the femoral artery in all cases showing hypertension or neck pulsation. In more cases will be found. Of the three cases, two, aged 15 and 9, are symptom-free. The third, aged 7, is easily tired and has had cramp in the legs at night for the last two years. Her blood pressure is normal. She was diagnosed by Dr. J. W. Brown at the age of 2½. The Crawford operation of resection of the coarctation and end-to-end anastomosis of the aorta is a severe one, and in symptomless cases the operative risk may well be greater than the danger of rupture of the aorta, bacterial aortitis, or heart failure. A remote risk of the operation may be from weakness at the suture line when atheromatous changes occur in the aorta. For these reasons it would probably be wise to reserve operation for young patients showing symptoms of cardiac embarrassment or ischaemia of the legs, because in them the prognosis without operation is bad enough to warrant the risk.

Atrial Septal Defect.—All three patients were girls. In diagnosis the radiological appearance of enlargement of pulmonary artery, including its right branch, with pulsation of the pulmonary vessels, was found the most useful sign. One had mitral stenosis as well (Lutembacher's syndrome), and she and one other had some shortness of breath on exertion. The third had no symptoms. This condition rarely causes heart failure before adult life and is usually

to be recognized in childhood unless cases with murmurs are examined radiologically.

Observation: Congenital Heart Disease.—In this group of eleven cases are three with loud systolic murmurs internal to the apex. No thrill has been felt, but it is considered probable that they are cases of ventricular septal defect. Two other cases show cardiac enlargement on screening. In another it is probable that the disability is entirely due to bronchitis and that the heart is normal. The remaining five cases are suspected of having pulmonary stenosis, atrial septal defect (2), patent ductus arteriosus, and the Eisenmenger complex. When the diagnosis is considered to be established they will be placed in the appropriate groups.

RHEUMATIC GROUP

This group comprises all the cases of proved and suspected mitral stenosis, those with a history of rheumatic fever or chorea with a noticeable systolic murmur, and those suspected of having active rheumatic infection. No cases of aortic incompetence without mitral stenosis have been seen in this series, though it is expected that in some of the cases of slight cardiac enlargement an early diastolic murmur may be heard on future examination.

Mitral Stenosis.—Of the 21 proved cases of mitral stenosis 13 were girls and 8 boys. Seventeen were between the ages of 10 and 15. Fourteen gave a history of rheumatic fever or chorea. In seven no history suggestive of rheumatic infection could be obtained. The commonest physical sign was a systolic murmur at the apex, which was heard in all. The first heart sound was loud in 15 and mid-diastolic murmurs and presystolic murmurs were heard in 14 and 6 respectively. The diastolic murmurs were always better heard lying than standing, and best when lying on the left side after exercise. On cardioscopy 16 showed enlargement of the left auricle in the right oblique position with barium in the oesophagus. Two others showed slight general enlargement with a straight left border, and three were normal on screening. None had severe disability, and, provided there had been no recent rheumatic activity, they were not restricted beyond what they could do in comfort. Two who had active carditis were admitted to hospital. Another, when apparently well, developed an acute infection with consolidation of the left lower lobe and died in a week.

Of the 13 cases under observation for mitral stenosis 8 are females and 5 males. Seven gave a history of rheumatic fever or chorea and had systolic murmurs with or without a loud first sound. Three had systolic murmurs with cardiac enlargement on x-ray examination. Three others had systolic murmurs only, but of such a character that these could not be passed immediately as innocent murmurs. It should be emphasized that the cases in this group are not restricted in any way whatsoever, but are being watched at intervals of six to twelve months to see how they develop.

CASES WITHOUT HEART DISEASE

These cases are most important, for they are healthy children whose whole lives may be blighted by a mistaken diagnosis of heart disease. A few examples may be quoted.

Girl aged 7; parents told "heart bad" when she was 2 years old. Never allowed games or drill, and spent one day a week in bed.

Girl aged 14. Examined on account of nose-bleeding at 5; told "valvular trouble." Since then had never been allowed games, drill, swimming, or dancing.

Boy aged 14½. Heart examined at 4; no games or drill since.

All these children have healthy hearts and are now playing full games without distress.

Innocent Murmurs.—These account for nearly half the total number of cases. They have been classified and their characteristics described by Evans (1947). The majority are better heard in the reclining posture. They have a soft blowing character and are usually diminished or abolished by deep inspiration. They do not occur early in systole, and a gap can often be detected between the first sound and the murmur. It is hoped that phonocardiography may assist in distinguishing these murmurs more clearly. Table II

TABLE II.—96 Healthy Children with an Innocent Murmur

Type (Evans's Classification)	No.	Boys	Girls	Third Heart Sound Present
Murmur of reclining posture ..	90	54	36	71
Murmur of upright posture ..	4	—	4	1
Parasternal murmur ..	2	1	1	2

shows the great preponderance of murmurs better heard in the reclining posture and the high proportion in which a physiological third sound was heard in such cases.

Triple Rhythm.—A third heart sound was heard in 100 cases. In five it was the only sign. In 83 it occurred in healthy hearts, in 3 with congenital heart disease, and in 14 cases under observation for possible rheumatic or congenital disease. The distribution is shown in Table III.

TABLE III.—100 Cases of Triple Rhythm

Cases without Heart Disease (83):				
Alone	5
With innocent murmurs	75
With anaemia, scoliosis, and pulmonary fibrosis (1 each	3
Cases with Congenital Heart Disease (3):				
Atrial septal defect	2
Coarctation of aorta	1
Cases under Observation (14):				
For mitral valvular disease	8
For congenital heart disease	6

Depressed Sternum.—Only one case occurred in this series. Evans (1946) has pointed out that with this deformity the heart may be flattened between the spine and the depressed sternum. This may give rise to a systolic murmur and also give an impression of cardiac enlargement by outward displacement of the apex beat. This apparent cardiac enlargement may be noted on cardioscopy in the antero-posterior position, but the true cause may be suspected from the unusual translucency of the cardiac shadow and be proved by examination in the oblique position. With deeper depression of the sternum the heart may be dislocated to the left, causing great displacement of the apex. The condition is harmless, and is important only as a possible cause of unnecessary invalidism.

Splitting of the First Heart Sound.—It is surprising that this was heard only once among 200 children, for it is a common sign. Its importance lies in the fact that it is often mistaken for the presystolic murmur of mitral stenosis. Splitting is best heard in the upright posture over the lower sternum; the first sound is not loud and there is none of the crescendo quality of the true presystolic murmur. It is in fact a simple splitting and not a murmur.

Displacement of the Heart.—Scoliosis is the commonest cause of displacement of the apex beat in children, and when this is outwards it may give rise to a suspicion of cardiac enlargement. The condition is usually recognized by observing that one shoulder is higher than the other. It is most easily seen on screening, when by rotating the patient to correct the deformity the normal size of the heart is apparent.

Other Factors

Blood Pressure.—This was recorded in 180 cases, and the results were examined to see whether there was any striking difference according to age, sex, or the presence of heart disease. The numbers are too small for statistical

analysis, but it was found that in healthy children under the age of 10 the systolic blood pressure was less than 100 mm. Hg in 60% of boys and 30% of girls.

Electrocardiography.—Only standard leads and CR1 were taken in the majority, as twelve-lead cardiograms were not started until late in the series. The more complete records should help in the assessment of right or left ventricular preponderance. It is not proposed to give here a detailed description of the present findings, but two observations can be made. Sinus arrhythmia of a degree easily perceptible to the eye without measurement was seen in 97 out of 195 cases. Of these, 68 out of 117 were in healthy hearts, 14 out of 42 in the congenital group, and 15 out of 36 in the rheumatic group, including three with active carditis. This supports the view that sinus arrhythmia is of no value in helping to determine the condition of the heart.

It has been suggested that a physiological third sound, prominence of the pulmonary artery on cardioscopy, and inversion of the T wave in CR1 may be linked as a triad of physiological right ventricular preponderance. The direction of the T wave in CR1 was therefore studied in 94 cases showing a third heart sound. It was inverted in 12, diphasic (—+) in 32, flat in 1, diphasic (+—) in 5, upright in 42, and bizarre in 2.

Radiological Examination.—The ease with which the cardiac silhouette can be seen in children contrasts pleasantly with the difficulty so often encountered in obese adults. The child's heart tends to look a little larger in relation to the size of the chest. Cardioscopy is of great assistance in attempting to separate the congenital malformations and in the early diagnosis of mitral stenosis. It is also of value as a check on clinical observation, and in more than one case in this series the appearance of cardiac enlargement led to re-examination, with the discovery of signs that had been missed before.

Restriction and Cardiac Invalidism

The proportion of those whose activities had been restricted on medical advice is shown in Table IV. In those without heart disease it was encouraging to note that

TABLE IV

Group	No.	Activities Restricted on Medical Advice				Total
		No Symptoms	Slight Symptoms	Moderate to Severe Symptoms	Unnecessary Cardiac Invalidism	
Healthy hearts ..	119	29	9	1 (neurosis)	39	39
Congenital ..	44	17	7	7	24	31
Rheumatic ..	37	16	2	8 (6 active)	18	26

although in the first hundred of the series 26 out of 55 had been restricted, in the second hundred only 13 out of 64 had had their activities curtailed. In view of the rapidity with which a cardiac neurosis can develop it is surprising that such a high proportion of those restricted had remained symptom-free. In contrast was a girl, referred on account of an innocent murmur, who complained of shortness of breath for the first time during the fortnight while waiting for an appointment at the cardiac department.

What limitation should be placed upon the activities of children with heart disease is a more controversial subject. All would agree that while any suspicion of active rheumatic infection exists rest should be advised, and in certain cases of congenital heart disease with severe disability there is no choice, for the heart itself imposes limitations. Patients with coarctation of the aorta in which a sudden strain may prove fatal should also have their activities limited.

These cases, however, are in the minority, and there are large numbers of children with gross signs of definite heart disease who have little or no limitation of exercise tolerance. Should they be prevented from enjoying the activities in which they are so keen to take part? On this subject we have the authority of Sir James Mackenzie (1917), who stated: "Children with a heart the efficiency of which is impaired will not injure it by over-exertion. Children are very sensitive to distress provoked by cardiac inefficiency and will themselves abstain without being told. . . . I cannot recall a single instance where I could reasonably attribute heart failure to a child's voluntary exertions. The same reasoning applies to the games of boys and girls; when they exert themselves and find pleasure in doing so it may be taken for granted that no harm results."

If this opinion is accepted—and I think it should be—the restriction in all those cases without symptoms or with only minimal symptoms becomes unnecessary, and these children may be allowed to indulge in games, their own feelings being the best guide. It is my opinion that from a cardiac point of view the only valid reasons for stopping a child's normal school activities are active rheumatic infection or disease causing cardiac embarrassment of a degree which makes exertion uncomfortable.

Discussion

The main objectives are that children with heart disease shall lead as full and happy lives as possible, and that no suspicion of heart disease shall be allowed to remain in the minds of those who are healthy. Too often the child with some innocent or benign cardiac condition has been kept from games, drill, swimming, and dancing—in fact all the pleasures of school life. School medical officers may change, and newcomers are chary of questioning the judgment of their predecessors. Once the child has been placed on the restricted list few dare to raise the ban, and it may be treated as an invalid through the whole of its school life. It is not surprising in these circumstances that it grows up neurotic.

It is not advocated that children with severe disability should be driven to undertake activities which they can perform only with difficulty. Even those with impaired efficiency may be able to join in all but the more strenuous forms of competitive sport. The majority of these children who have been deprived of physical exercise in school are most anxious to join in with the others, and in unofficial games are often reported to be above average in the activity they display. They resent bitterly not being allowed to lead a normal life, and their joy at being told that they can do so knows no bounds. It is inevitable that such liberation of children who have been over-protected for years will sometimes cause parents to wonder whether the past restriction has been really necessary. Such difficulties are encountered only in the early months, and disappear when all cases are being referred to a cardiac clinic as soon as an abnormality is noticed and before restriction is instituted.

It might be thought that this work should be confined to centres where all the more specialized investigations such as angiocardiology, kymography, and cardiac catheterization with blood gas analysis, are available. The proportion of cases in which these are necessary for diagnosis is small, and while they add to the observer's interest they are not often essential for the benefit of the patient. It will be agreed that cardiac surgery should be undertaken only at a very few centres, so that a small number of surgeons may acquire the necessary experience to perform these operations with the greatest efficiency. When these special investigations are considered necessary they could be carried out at such a centre before operation. It would

is impossible to provide enough of these highly specialized clinics to examine more than a small proportion of the children with cardiac abnormalities. It should not be difficult, however, to cover the country by a series of centres, so that every child in whom any cardiac abnormality is suspected should have the benefit of examination and supervision by a physician specializing in cardiology. In this way much unnecessary cardiac invalidism would be prevented.

Summary

The work of a children's cardiac clinic is described, and a report presented of the first 200 cases seen.

It is suggested that the setting up of similar clinics in areas where they are not already in operation would add to our knowledge and be of great benefit to the children.

I should like to thank Dr. John Matthews, senior school medical officer, Brighton, for his willing co-operation, and Miss V. Amato, radiographer to the department, for her technical assistance.

HOG-STOMACH EXTRACT AND CASEIN HYDROLYSATE IN PEPTIC ULCER

BY

A. W. KAY, M.D., F.R.C.S.

R. A. JAMIESON, F.R.C.S.

AND

W. E. SMITH, M.A., M.B., Ch.B.

(From the Peptic Ulcer Clinic, Western Infirmary, Glasgow)

It is notoriously difficult to evaluate the results of treatment in a disease such as peptic ulcer which follows an irregular course of relapse and remission. A spontaneous remission (especially if it should last for several weeks) is apt to be falsely attributed to the method of treatment in operation at the time. A system of study has been evolved in this clinic which would seem to avoid such a fallacy. The purpose of this paper is to describe the experimental method used to illustrate its application by reporting an investigation of two forms of treatment recently advocated—namely, the administration of hog-stomach extract and of casein hydrolysate.

Method of Study

The test substance is administered for three months and then withheld for three months, this sequence being repeated without reference to the presence or absence of dyspepsia. By the end of twelve months there are available for comparison two test periods and two control periods, during which (in the absence of benefit from the test substance) relapses can be expected with equal frequency. It is to be noted that relapses normally terminate spontaneously, and consequently the first improvement after the beginning of therapy must be discounted.

There can be little doubt that, in general, relapses tend to be more frequent in winter than in summer, and for this reason it was felt that the clinical trial should cover the period of a full year. The possibility was foreseen that in

the periods between the administration of the test substance the patients might regard themselves as untreated. To minimize this the proposed plan of treatment was explained at the start; partly through this explanation, and partly through conversation with other patients undergoing the same test, the control periods came to be accepted as an integral part of a planned course of treatment. Finally, patients were interviewed at the same intervals of time during the test and control periods so that the records might have the same degree of precision.

All the patients selected for study had radiological evidence of duodenal or gastric ulceration, and in each case the periodicity of relapse and of remission was well defined. Every patient had had symptoms for many years (average 12½ years) and the chance of spontaneous cure was considered to be remote. No change was made in the customary dietary habits of the patients save in one small group treated by intensive casein hydrolysate therapy (see below). Alkalis were permitted when pain was severe.

Hog-stomach Extract

The beneficial effects of feeding human gastric juice from normal subjects to patients with peptic ulcer have been described by Morrison (1945a). In an attempt to explain the prompt relief of symptoms it was suggested that the normal gastric mucosa is capable of elaborating a principle which protects the stomach from self-digestion and peptic ulceration. Developing this hypothesis, Morrison (1945b) was successful in preventing the occurrence of cinchophen ulcers in dogs by feeding them a preparation extracted from the mucosa and submucosa of the hog's stomach and duodenum. This was done with the intention of providing the "protective factor."

We present the results of a clinical trial of "pepsac," a commercial extract of fresh hogs' stomachs, in patients with peptic ulcer.

Dosage.—Pepsac was administered in doses of one tablespoonful (approximately 30 g.) three times a day in any vehicle palatable to the individual. In order to avoid destruction of any thermolabile active principle the temperature of the mixture was not allowed to exceed blood heat.

Results.—Observations were made on 41 patients (33 duodenal ulcer, 7 gastric ulcer, 1 stomal ulcer), with the following results:

Incomplete trial	8
? Incomplete trial or ? failure	7
Failure	17
Benefit	9

The patients given an incomplete trial include six who could not tolerate the preparation and two who defaulted. Seven patients continued to have severe disability, and the trial was abandoned in favour of in-patient hospital treatment; it is a matter of opinion whether these should be classified under "incomplete trial" or "failure." The 17 patients classed as failures (15 duodenal, 2 gastric) experienced no improvement in either the frequency or the severity of their relapses. In the remaining 9 patients (5 duodenal, 3 gastric, 1 stomal) some degree of benefit was obtained: in four of these the relapses became shorter and the remissions longer, and in five the periodicity was unchanged but the attacks were said to be less severe. The chart provides a diagrammatic representation of the clinical progress in two experiments and illustrates the method of study. During the period of investigation only one patient failed to gain weight.

Comment.—In most cases the addition of pepsac to the diet led to no symptomatic improvement despite a gain

in weight. Although the preparation is clearly nutritious there is no evidence that it contains an anti-ulcer factor.

Casein Hydrolysate

Co Tui *et al.* (1945, 1946, 1947) found that hyperalimentation, with protein hydrolysate promptly relieved peptic ulcer distress. This benefit was ascribed to the ease with which protein hydrolysate can be assimilated and used for tissue-building, and also to its properties as an antacid.

We present the results of a clinical trial of "casydrol" in patients with peptic ulcer. Casydrol is an enzymic hydrolysate of fat-free whole milk containing approximately equal parts of amino-acids (with polypeptides) and readily assimilable carbohydrate.

Dosage

In one group of patients one heaped tablespoonful of casydrol was given three times a day (approximately 50 g. daily). This amount was considered to be adequate, as our patients regarded casydrol as "medicine" and took it in addition to their normal diet.

In a second group we departed from the method of trial described above in order to repeat the experiments of Co Tui *et al.* (1945). For this purpose seven patients were given casydrol exclusively for seven days. Hourly feeds consisting of four tablespoonfuls of casydrol in warm water were given from 7 a.m. until 9 p.m. The daily intake of casydrol was 600 g., providing a yield of 2,160 calories. On completion of this seven-day intensive course patients were given normal diet with a casydrol feed between meals. For this experiment seven male patients suffering severe duodenal ulcer pain were admitted to hospital. This was considered necessary, as it seemed unlikely that even the conscientious peptic ulcer patient would adhere to hourly feeding of a rather unpalatable mixture in the absence of supervision. Although in hospital, these patients were ambulant for the greater part of each day.

Results

1. Casydrol as a Supplement to Normal Diet.—Casydrol therapy was given to 16 patients (13 duodenal, 3 gastric). Four patients defaulted after six to eight weeks of treatment, during which symptoms had remained unchanged. These patients were regarded as having had an incomplete trial. Ten patients who continued to have pain while on treatment and in whom there was no improvement in the periodicity of relapse and remission were considered to be failures. In two cases a severe relapse was curtailed by the administration of casydrol, but in only one was the remission longer than usual. All patients gained weight

on casydrol therapy, the increase varying between 1½ and 21 lb. (0.68 and 9.53 kg.).

2. Casydrol as Sole Source of Food Nitrogen.—Brief summaries of the seven cases treated by intensive casydrol therapy follow.

Case 1.—Man aged 30. Pain was relieved on the fifth day of treatment, and he remained symptom-free on return to the plus casydrol. Pain recurred on the 14th day, and he had a haematemesis on the 30th day. Weight gain, 2 lb. (0.91 kg.) (Failure.)

Case 2.—Man aged 28. Pain remained unchanged in frequency and in severity at the end of the seven-day course of treatment. Gained 2½ lb. (1.13 kg.). (Failure.)

Case 3.—Man aged 25. Symptom-free after 48 hours' treatment. Dismissed without pain on the eighth day. Weight gain, 1½ lb. (0.68 kg.). (Improvement.)

Case 4.—Man aged 34. Symptom-free on the fifth day of treatment. Severe recurrence on the last day of treatment. Continuous pain for the next six weeks. Gastrectomy advised. Weight gain, 3 lb. (1.36 kg.). (Failure.)

Case 5.—Man aged 42. Very severe pain, unchanged after three days' treatment. Gastrectomy performed for duodenal ulcer. (Failure.)

Case 6.—Man aged 31. Pain still present after treatment but less frequent and less severe. Improvement maintained for six weeks. Weight gain, 4 lb. (1.81 kg.). (? Improvement.)

Case 7.—Man aged 45. Pain unchanged after seven-day course of treatment. Weight gain, 1½ lb. (0.68 kg.). (Failure.)

Comment.—The addition of casydrol to the customary diet led to symptomatic improvement in only two out of 12 patients despite a gain in weight in all. Co Tui reports that in 27 cases with pain as the presenting symptom hyperalimentation with "amigen" and "dextri-maltose" as the sole source of nourishment gave complete relief to 24 patients within 48 hours. We have been unable to confirm these results using casydrol. Casydrol and amigen are both enzymic protein hydrolysates: each gramme of casydrol yields 3.6 calories and each gramme of amigen yields 3.7 calories.

Summary

A method of clinical trial well suited to the evaluation of peptic ulcer therapy is presented.

The results of treating peptic ulcer with a commercial preparation of hog's stomach fail to support the assumption that this substance contains an anti-ulcer factor.

Treatment with a commercial preparation of protein hydrolysate was carried out by giving it as a supplement to the ordinary diet or, alternatively, by giving it intensively for a short period as the sole source of nourishment. The patients gained weight, but their dyspepsia did not improve.

We are indebted to Benger's Ltd. and Genatosan Ltd. for providing a generous supply of casydrol and for providing information on its composition.

The Ministry of Health states that some management committees have been making a free issue to patients of sweets or tobacco or paying pocket-money in cash in hospitals where this was established practice before the appointed day. Except in mental hospitals, and mental deficiency institutions, this should now cease and patients should be expected to pay for tobacco or sweets supplied to them (i.e., bought on their behalf). Patients who have no means of their own (and no pension or benefit from the Ministry of National Insurance) may receive from the National Assistance Board a comforts allowance of 5s. a week, and such cases should, if the patients wish it, be referred to the area officer of the board. The Minister suggests, also, that the committee or board might consider providing from their "free" money sweets—and pocket-money in appropriate cases—for children in their hospitals.

HYPERINSULINISM DUE TO AN ISLET-CELL ADENOMA

A CURE, WITH METABOLIC STUDIES BEFORE AND AFTER OPERATION

BY

W. G. DUNCAN MURRAY, M.B., Ch.B.

(From the Aberdeen Royal Infirmary)

Hyperinsulinism due to an islet-cell adenoma of the pancreas is not a common condition. From 1931, when an operative cure was first recorded by Carr *et al.*, until 1945, only 56 cases of cure had been reported (Walker and Boger, 1945). Some cases have since been recorded, but the diagnosis is occasionally missed simply because the condition is not kept in mind. In many of the published cases the initial diagnosis was wrong and the condition was confused with narcolepsy (Walker and Boger, 1945), cerebral tumour (Womack, Gnagi, and Graham, 1931), and psychosis (Lups, 1944). Sendrail (1947) discussed the history of this condition and gave an exhaustive review of the older literature.

The following case is reported because the history was the key to the diagnosis, and the standardized insulin-tolerance test of Fraser and Smith (1941) was performed. These authors standardized this test for the diagnosis of endocrinological disorders of glucose metabolism. Many writers (Fraser, MacLay, and Mann, 1938; Fraser, Albright, and Smith, 1941; Burtness, Koehler, and Saint, 1941; Sendrail, 1947) have stressed the importance of the response to insulin injection in the diagnosis of hyperinsulinism, but a search of the literature has failed to reveal a case in which the standardized intravenous test has been carried out.

Case History

A 40-year-old housewife was admitted to Aberdeen Royal Infirmary on July 19, 1947, for investigation. The history was obtained from the patient and her husband, both of whom were good witnesses.

Nine months before admission she began to have occasional periods of drowsiness in the mornings and difficulty in waking. These attacks lasted for one to two hours and she was well for the remainder of the day. Her husband noticed a change in her behaviour during the attacks: she often wandered aimlessly about the house and wept for no apparent reason. Retrograde amnesia was occasionally associated with the drowsiness.

The attacks became more frequent, and on one occasion, three months before admission, she suffered from general weakness of the legs and was unable to move her right arm. She was given a whisked egg and milk and quickly recovered. Her physician prescribed amphetamine sulphate, one 5-mg. tablet to be taken at 6 a.m. and another at 8 a.m. She took these daily for eighteen days, and during that time and for two weeks after she was free from symptoms.

Ten days before admission she had a three-hour period of amnesia with automatism. During that time she wandered outside to the washing-house, lit the boiler fire, and did a considerable amount of washing. Her husband found her in a dazed condition, with a burn of her arm and parts of her clothing charred. He took her indoors and revived her by giving her food.

For one week before admission she had periods of drowsiness every morning, but now they were more severe and lasted up to eight hours. During an attack she had never been seen to shake or go stiff, to have incontinence, or to bite her tongue. In addition to the burn she had only once fallen and hurt herself. There had been no personality change apart from the abnormal behaviour during the attacks. At no time had she had the sensation of warmth or sweating associated with the drowsiness. Her appetite, though poor, showed no change, and her weight remained constant.

There was nothing of note in the family and personal histories. She had two healthy children aged 18 and 10 years.

Physical Examination.—The patient was fairly well nourished; height, 5 ft. 3½ in. (161 cm.); weight, 9 st. 7 lb. (60.5 kg.). She was intelligent, but often her actions were of a childish nature. No abnormality was found on physical examination. Her blood pressure was 126/66. There were no masses or tenderness in the abdomen. No signs of hypothyroidism or other endocrine disorder were present. Urinalysis was negative, and neither sugar nor urobilinogen was present.

Special Investigations.—X-ray examination showed no abnormality of the bones of the skull. No abnormal shadows appeared in the abdominal skiagram and no abnormality of the alimentary tract was demonstrated by barium meal. In particular the duodenum was normal. The visual fields were full and the fundi normal. Fasting blood-sugar estimations were carried out from July 21 (Chart 1). The cerebrospinal fluid showed

CHART 1.—Fasting blood-sugar levels before and after operation, with incidence of hypoglycaemic attacks.

no abnormality, but the sugar content was 42 mg. per 100 ml., the blood-sugar level at the same time being 100 mg. per 100 ml. The blood Wassermann reaction was negative. Blood examination showed: haemoglobin, 102%; red cells, 5,010,000; colour index, 1.02. The red cells were normal and no macrocytosis was present. Plasma chloride as NaCl was 525 mg. per 100 ml.; plasma cholesterol, 200 mg. per 100 ml. The basal metabolic rate was minus 16.

Description of the Attacks

Spontaneous.—These varied in detail from day to day, but followed the same general pattern. The patient appeared to wake normally, but soon fell into a drowsy condition and appeared to be asleep. She resisted attempts to wake her and would turn away, pull the bedclothes over her head, and curl up in bed. She showed some perseveration and repeated such phrases as "I'm all right," "I'm not asleep," and "Leave me alone." Occasionally when left alone she chattered to herself. Her speech at all times was clear. She would not carry out orders to move arms or legs or to sit up, and at times tended to be negativistic, gripping her eyes tightly when attempts were made to open them. There was no significant change in pulse or blood pressure; skin colour and temperature remained the same and at no time during an attack was sweating a feature. During the more severe attacks twitching of the facial muscles and tremors of the fingers and eyelids were seen. The pupils were dilated and reacted briskly to light. The muscles appeared hypotonic; the muscle reflexes were exaggerated, but muscle clonus could not be elicited, and the plantar responses were flexor. The attacks were quickly terminated by administration of carbohydrate, either by mouth or intravenously, without the patient's knowledge. Retrograde amnesia was present.

Induced.—Only during the insulin-tolerance test were the spontaneous attacks fully reproduced, but in addition sweating and the sensation of warmth were present. There was no retrograde amnesia after the hypoglycaemic attacks that occurred during the glucose-tolerance and insulin-tolerance tests and it was possible to elicit the following symptoms. The most constant of these were increasing frontal headache and blurring of vision. Less severe were the weakness, lassitude, and increasing hunger; the latter was present only in the glucose-tolerance tests, and may have been due to the length of the total fasting

period (eighteen hours with only 50 g. of glucose) or to the fact that meantime other patients were being fed.

Specific Investigations

Glucose-tolerance Tests.—Glucose, 50 g., was given after a twelve-hour fasting period, and blood-sugar estimations were carried out every half-hour for six hours. The blood-sugar

CHART 2.—Glucose-tolerance test before operation.

though the symptoms were aggravated, there was no change in the blood-sugar level (Chart 2).

Insulin-tolerance Test.—This was carried out as recommended by Fraser and Smith (1941). The patient was given extra carbohydrate for four days before the test was carried out. Insulin in the dose of 3.7 units per square metre of body surface was given intravenously and the blood-sugar levels were estimated at intervals (Chart 3). Normally the maximum fall to about 50%

CHART 3.—Insulin-tolerance test before operation. Dotted line shows composite normal from six cases.

higher is the index. **Report**—120th minute sample, 81% of fasting sample (normal=90–110%). Index of hypoglycaemia responsiveness, 449 (normal=470–620). **Interpretation:**—The curve shows hypoglycaemia unresponsiveness. In the absence of evidence of hypopituitarism, adrenocortical insufficiency, liver disease, or marked emaciation from anorexia nervosa this finding is suggestive of hyperinsulinism.

From the history and investigations a clinical diagnosis of organic hyperinsulinism was made and surgical treatment advised.

Operation

On Aug. 20 an operation was performed by Mr. G. Gordon Bruce. Glucose, 50 g., was given at four hours and one hour before operation. The anaesthetic used was nitrous oxide, oxygen, and ether, the latter because it tends to raise the blood-sugar level. The abdomen was opened by a right paramedian incision and the gastro-colic omentum was divided. The stomach was then hooked up by two malleable retractors and the transverse colon displaced downwards, exposing the entire anterior surface of the pancreas. At this point a bluish tumour mass about 2 cm. in diameter immediately became visible, lying slightly to the left of the midline on the lower border of the pancreas near the junction of the tail with the body of the pancreas. This lower border was freed so that the tumour could be held between the finger and thumb, a series of chain

sutures of fine linen was inserted into the pancreas, and the mass was excised by cutting freely into the surrounding tissue. The gap in the pancreas was then sutured and the gastro-colic omentum closed. A soft rubber drain was left *in situ*.

Pathological Report.—"The tumour is 7 mm. in diameter and is embedded in normal pancreatic tissue. There is no true capsule to the tumour, but the surrounding pancreatic tissue is flattened and compressed. The tumour is vascular, and the cells show acinar formation. There is no evidence of malignant change. Special staining methods fail to demonstrate that the tumour cells are of the β cell type. **Diagnosis:**—benign islet-cell adenoma."

Post-operative Progress

There have been no more drowsy attacks, and the patient is well (sixteen months after operation). Immediately after the operation blood-sugar estimations were carried out at approximately four-hourly intervals, and after an initial rise to 187 mg. per 100 ml. and a fall to 162 mg the blood-sugar level rose steadily to a maximum of 197 mg at the twenty-fourth hour, though nothing but sips of water were being given. The hyperglycaemic period lasted four days and was accompanied by slight glycosuria for two days. After four days the fasting blood-sugar level fell to normal (average 86 mg. per 100 ml.). Convalescence was uneventful, apart from a small pancreatic fistula which discharged for five weeks.

Forty days after operation the following tests were carried out:

Glucose-tolerance Test.—This showed a normal response, although at the third hour the blood sugar fell to a low level (Chart 4).

Insulin-tolerance Test (Chart 5).—**Report:**—120th minute sample, 92% of fasting sample. Index of hypoglycaemia responsiveness, 488. **Interpretation:**—Curve shows: insulin resistance (maximum fall in blood sugar delayed beyond thirty minutes after intravenous insulin), and normal hypoglycaemia responsiveness.

CHART 4.—Glucose-tolerance test after operation.

CHART 5.—Insulin-tolerance test after operation. Dotted line shows composite normal from six cases.

Discussion

The present case illustrates the steps by which a diagnosis of organic hyperinsulinism can be arrived at, first by the demonstration that the patient's symptoms are due to spontaneous hypoglycaemia, and then by the elucidation of the special features that distinguish organic hyperinsulinism from other causes of spontaneous hypoglycaemia.

Of the three main causes of spontaneous hypoglycaemia mentioned by Conn (1940)—hepatogenic hypoglycaemia, functional hyperinsulinism or cryptogenic hypoglycaemia (found in persons of unstable personality and almost always associated with psychoneurotic symptoms), and organic hyperinsulinism from an adenoma or carcinoma of islet tissue—the first two could be excluded. There was no clinical evidence of hepatic insufficiency and the glucose-tolerance test did not show the high plateau curve characteristic of liver disease. The intolerance to fasting, with hypoglycaemic blood-sugar levels, the lack of correlation of the attack with previous ingestion of a carbohydrate meal, and the patient's stable personality before the onset of the

present attacks excluded the condition of cryptogenic hypoglycaemia.

The occurrence of hypoglycaemia unresponsiveness in the insulin-tolerance test, with restoration of a normal response after removal of the islet-cell adenoma, indicates a causal relationship and affords confirmation of the suggestion of Fraser, Albright, and Smith (1941) that organic hyperinsulinism would be expected to produce hypoglycaemia unresponsiveness in the insulin-tolerance test.

This case is typical of the cases of islet-cell adenomata already reported and illustrates many points. It shows the successful results of surgery in hyperinsulinism due to islet-cell adenomata. Medical treatment is indicated in cryptogenic hypoglycaemia but is dangerous in organic hyperinsulinism. A high-carbohydrate diet tends to fatten the patient and so makes for a poor operative risk later. Repeated prolonged hypoglycaemic attacks can cause permanent damage to the central nervous system. These tumours show a tendency to become malignant and there should be no delay in attempting operation.

From this case it would appear that the coma, muscular twitches, and altered behaviour—equivalent to Himwich's (1944) cortical and subcortical phases of hypoglycaemia—were due to the low blood-sugar level. The symptoms such as lassitude, headache, and visual disturbances would seem to be due to adrenaline secretion reflexly induced by a sudden fall in the blood-sugar level. The small dose of adrenaline given during the glucose-tolerance test seemed to aggravate the symptoms of hypoglycaemia without altering the blood-sugar level. This case also showed that amphetamine sulphate could temporarily relieve the hypoglycaemic attacks, presumably by raising the blood-sugar level.

A short post-operative period of hyperglycaemia has been found in cases in which blood sugars have been estimated. This would appear to be due to the partial depression of the activity of the normal islets, while the requirements of the body were covered by the adenoma. The insulin resistance after operation may be due to persistence of a high level of the insulin antagonists, such as the glycotropic factor of the anterior pituitary.

Finally, the case illustrates the great importance of accurate differential diagnosis in cases of spontaneous hypoglycaemia, the difficulty of attempting to diagnose hyperinsulinism by the glucose-tolerance test alone unless this is prolonged for several hours, and the value of the insulin-tolerance test in diagnosing organic hyperinsulinism.

Summary

A case of organic hyperinsulinism is reported. The condition was cured by the removal of an islet-cell adenoma. Glucose-tolerance and insulin-tolerance tests were carried out before and after operation. The usefulness of the latter in the differentiation of hyperinsulinism from other causes of hypoglycaemia is emphasized.

I wish to thank Professor John Craig for permission to publish this case, and Professor J. Young and Dr. W. M. Davidson for the pathological report. I am indebted to Dr. Ian A. Anderson for carrying out the insulin-tolerance tests and for his help and guidance so freely given.

RINGWORM OF THE SCALP

TREATMENT BY X-RAY EPILATION WITHOUT SUBSEQUENT LOCAL APPLICATION

BY

F. L. LYDON, M.B., M.R.C.P.

Dermatologist, Ringworm Clinic

T. STEPHANIDES, M.D., D.M.R.D.

Assistant Radiologist

AND

T. M. ROBB, M.R.C.S., L.R.C.P., D.M.R.T.

*Director, X-ray Department
Lambeth Hospital, London*

The many ingenious attempts made by various schools to increase the efficiency of local treatment in cases of tinea capitis have so far been unsuccessful, and the latest report by Brain *et al.* (1948) on the effect of fungicides in penetrating bases, although suggestive, must be evaluated in the light of further experience before we can hope to dispense with epilation by x rays as the method of choice in these cases.

Sequeira, Ingram, and Brain (1947) state that "it must be realized that they [x rays] have no parasitocidal action, but are simply used to remove the hair, after which continuous treatment must be applied to the bald scalp in order to eradicate the fungus before the hair grows." Again, Becker and Obermayer (1947) say: "It is the long period between epilation and regrowth that gives roentgen irradiation a superior advantage over all other methods of epilation, for during this time the surface of the scalp can be rendered antiseptic. . . . After epilation is complete local treatment . . . is carried out vigorously until no evidence of the disease can be found."

It can be seen from the preceding quotations that x-ray epilation is regarded only as ancillary, and that it is the local application of fungicides that really brings about cure. The late Mr. G. Stebbing, Director, X-Ray Department, Lambeth Hospital, however, believed that local treatment was unnecessary, and it has been the policy at the Lambeth Clinic to treat all cases of tinea capitis by the following method.

Method

X-ray epilation is carried out by the four-field technique (four main fields and one subsidiary field), the following factors having been worked out by Dr. L. H. Clark.

Victor KX10 Apparatus.—K.V.P. 100. Half-value layer 1.6 mm. Al. Tube current 7mA. Primary volt reading 75v. (selector switch—high). F.S.D. 19.5 cm. Open field 16.6 in. (42 cm.) diameter.

Dose.—Four main fields: 500 r skin dose (backscatter factor. 1.24). Subsidiary field: 124 to 160 r according to the size of the patient's head, the average being 142 r. In very small children this, of course, is omitted.

Instructions to Patients.—The patients are simply instructed to wash the scalp with soap and warm water from the fifteenth day after treatment until epilation is complete. A cotton cap is provided by the department, and the patients are advised to make another like it. The patient wears one of these caps while the other is sterilized by boiling on alternate days.

After-care.—Inspection is carried out by the clinic about three weeks later, and thereafter as is considered necessary. Local application of ung. adipis lanae is prescribed to soften

and facilitate the removal of any scabs or scales that may be present. The occurrence of secondary infection is treated on general principles, but these cases were few in this series, which indicates the high standard of the school medical organization in detecting cases at an early stage.

With the factors given above, epilation has always been on the whole satisfactory. Occasionally small tufts of hair have remained in the centre of a well-epilated area or towards the periphery of the scalp. In most cases the hairs are loose and can be easily removed by a pair of forceps. Sometimes, however, these tufts resist extraction, but since infection of these hairs is not present, as shown from the following results, recontamination of the growing hair never follows and they can be ignored. No complications result from therapy except occasional headache and vomiting on the night of treatment, and there were no cases of alopecia, local or general.

Review of Cases

To check the results of treatment carried out on the lines described above, follow-up cards were sent to 103 patients whose epilation dated from eight months and over requesting them to attend the x-ray department for review. These 103 cases comprised: 71 with a laboratory diagnosis of *Microsporon audouini*, 27 with a laboratory diagnosis of ringworm fungus, and 5 diagnosed on clinical grounds and by Wood's light.

Forty-eight of these patients responded in person and were examined by us clinically and by Wood's light. They all proved to be free from infection and their hair and scalp were in excellent condition. Of the remaining 55 patients, 13 had left London and could not be contacted, and 42 were examined at their schools by the courtesy of the medical officer of the S.E. and S.W. divisions, who kindly forwarded reports on the condition of these patients. All without exception were completely well and their hair and scalp were described as being in a healthy state.

From these figures it can be stated that out of 103 patients with ringworm of the scalp who received no treatment other than x-ray epilation 90 (87.37%) showed no signs of relapse after an interval of time ranging from eight to twenty-four months. These 90 were made up as follows: 68 cases of *M. audouini* infection, 19 of ringworm fungus, and 3 diagnosed clinically and by Wood's light. It should be added that as no complaints have been received concerning the other 13 cases it can be assumed on fairly certain grounds that they too have remained free from relapse. This being so, the total percentage of cures may have reached 100.

Time Lost from School.—To date it has been our policy to keep the children away from school for about two to two and a half months, when the new hair showed signs of regrowth. We feel that in view of the above results an earlier return is possible, as the loss of a full term is often a serious handicap to these children. Perhaps, with a good epilation, six weeks would be sufficient in the great majority. Further work will be necessary, however, before a final decision can be taken on this point.

Summary

One hundred and three cases of tinea capitis treated solely by x-ray epilation are reviewed after an interval of eight to twenty-four months.

The results show that local application of fungicides is unnecessary—at least in cases of *M. audouini* infection. It may be added that the fact that the cases were consecutive and were free after the lapse of such an interval is ample justification of the view of the late Mr. G. Stebbing, who held that local

treatment was unnecessary, and that although x rays were not parasitocidal they either had the power to reduce the vitality of the fungus or brought about some tissue change which made it less easy for chance spores remaining to contaminate the new crop of hair.

FULMINATING MENINGOCOCCAL SEPTICAEMIA

AN ACCOUNT OF THREE CASES, WITH ONE RECOVERY

BY

PETER TURNER, M.B., B.S.

AND

R. V. DENT, M.B., B.Chir., M.R.C.P.

Resident Physician, General Hospital, Rochford, Essex

Fulminating septicaemia is one of the rarer manifestations of meningococcal infection. It occurred in 24 (3.4%) Banks's (1948) series of 706 cases, and American authors give its incidence as about 1% (Sweet, Dowling, and How 1947).

Though it may be preceded by a few days of mild infection of the upper respiratory tract, the onset is usually sudden, with fever, rapid respirations, and cyanosis, simulating early pneumonia. Petechiae appear within a few hours and quickly enlarge to form purpuric blotches. Peripheral vascular failure occurs early, with a rapid feeble pulse, very low blood pressure. Meningism is absent at first, may appear terminally. In untreated cases death occurs 24–36 hours. Necropsy often reveals adrenal lesions, the most striking of which is massive bilateral haemorrhagic destruction (sometimes known as the Waterhouse-Friderichsen syndrome).

Since 1940, reports of successful treatment with sulphamides and adrenal cortical extract have been published. With the additional help of penicillin Banks (1948) believes 50% of cases may recover.

We saw three sporadic cases within a year at a general hospital. One of these recovered.

Case 1

A female laundry worker aged 21 was quite well till 2.30 p.m. on Jan. 27, 1946, when she awoke with pains in her legs, which grew rapidly worse and spread to her whole body. Her throat became sore, and during the morning dark blotches appeared on her trunk and limbs.

She was admitted to hospital at 3.30 p.m., and was seen by a well-built woman, gravely ill. The temperature 102° F. (38.9° C.), pulse 112, and respirations 24. Purpuric blotches involved the face, neck, trunk, and limbs, and also buccal mucous membrane and conjunctivae. The pulse rapid, feeble, and regular. Blood pressure was 75/55. There were no signs of meningism and the urine was normal. White blood cells totalled 15,000 (83% polymorphs). Bleeding clotting times and capillary resistance were normal.

Her condition deteriorated rapidly, the pulse became inextinguishable, and the blood pressure too low for estimation. She sank into a coma, and a trace of neck rigidity was noted. Pupils were irregular and the limbs flaccid. At 5.15 a.m. on Jan. 28 the cerebrospinal fluid was turbid. Cells numbered 12 (99% polymorphs). Gram-negative intracellular diplococci

were found in deposit. Culture was sterile. She died at 6.40 a.m., 28 hours after the onset.

Necropsy was performed by Dr. D. J. O'Brien five hours after death. Widespread partly confluent intracutaneous haemorrhages from pin-point size to 15 cm. diameter were seen. There was thin pus over both cerebral hemispheres, but not at the base of the brain. Petechiae were present in parietal and visceral pleura, pericardium, and peritoneum. A small fleshy thymus gland was found. The spleen was twice the normal size. The right suprarenal was congested; the left had small haemorrhages in the medulla. No lesion of the muscles was noted.

Microscopical Examination.—The thymus was normal. The adrenals showed congestion of all capillaries but no frank haemorrhage. Cells of outer layers of cortex of both glands appeared necrotic. Diplococci were seen in films of the pus over the brain, and meningococci (Type I) were cultured from the heart blood.

Death was considered to be due to fulminating meningococcal septicaemia.

Case 2

A boy aged 3 was taken ill at midday on Oct. 11, 1946. At 7 p.m. he was febrile and breathless, and was sent to hospital as a case of early pneumonia.

On admission at 10.30 p.m. he looked severely ill, with grey cyanosis. The temperature was 104° F. (40° C.), pulse 160, and respirations 44. There was a trace of neck rigidity. The lungs were normal. A petechial rash was seen on the upper part of the trunk. During the next hour this rash developed with great rapidity until the whole trunk and limbs were covered with purpuric blotches. A clinical diagnosis of fulminating meningococcal septicaemia was made, and courses of penicillin, 30,000 units intramuscularly three-hourly, and oral sulphadiazine, 1 g. followed by 0.5 g. four-hourly, were begun. C.S.F.: crystal-clear; pressure, 120; no cells; protein, 20 mg. per 100 ml.; no organisms seen; culture sterile. Penicillin, 15,000 units, was injected intrathecally.

At 8 a.m. on Oct. 12 his condition was obviously much worse. The temperature was 106° F. (41.1° C.), pulse uncountable, and respirations 72. Blood pressure was too low for estimation. Neck rigidity was definite and Kernig's sign positive. C.S.F.: turbid; pressure, 140; cells, 3,200 per c.mm. (99% polymorphs); protein, 180 mg. per 100 ml.; no organisms seen; culture sterile. Penicillin, 15,000 units, was injected intrathecally. White blood cells numbered 33,000 (polymorphs 80%). Scrapings from a purpuric patch were cultured, but pathogenic organisms were not isolated. It was now thought that acute adrenal insufficiency might well have developed, and though the child appeared moribund it was decided to try the effect of administering adrenal cortical extracts (22 hours after the onset). The possibility of the cellular reaction in the C.S.F. being the result of previous intrathecal penicillin was also considered.

At 10 a.m. desoxycortone acetate, 5 mg., was injected intramuscularly. An intravenous infusion of 5% dextrose in normal saline was set up, and three-hourly intravenous injections were given by the infusion tubing of: 2.5 ml. of "eucortone"; 0.1 ml. of 1 in 1,000 solution of adrenaline hydrochloride; and 0.5 g. of soluble sulphadiazine. At 2 p.m. the temperature was 99.4° F. (37.55° C.), pulse 120, and respirations 48. Very great improvement was obvious. His colour was rosy, the pulse was easily felt, and the blood pressure was 100/60. Mild neck rigidity and Kernig's sign were still present.

On Oct. 14 there was no return of peripheral vascular collapse. A trace of oedema of hands and feet was present, which was considered to be due to excess of adrenal cortical extract and saline. Infusion and eucortone were therefore discontinued, after totals of 4 pints (2.3 litres) and 45 ml., respectively. Sulphadiazine, 0.5 g. three-hourly orally, and intramuscular penicillin were continued. On Oct. 16 progress was satisfactory, with only a trace of neck stiffness. C.S.F.: clear fluid, sterile; pressure, 180; cells, 360 (99% polymorphs); protein, 35 mg. per 100 ml. On Oct. 18 the purpuric patches were fading, but seven of the large ones on the back and

buttocks were sloughing. Chemotherapy was stopped after a total of 1,180,000 units of penicillin and 35 g. of sulphadiazine had been given.

Convalescence was delayed by infection of the sloughed purpuric patches and of the infusion wound, but this responded to a further course of penicillin.

In May, 1947, he was quite normal for his age, the only sequelae being the scars of his infusion wound and sloughs. A radiograph of his abdomen showed no evidence of calcification of the adrenals.

Case 3

A schoolgirl aged 15 was well till Jan. 26, 1947, when she complained of a cold in the head. At bedtime she felt "shivery" and had an aching pain in the right shoulder and arm. At 1.30 a.m. on the 27th she vomited, and at 5.30 a.m. her parents observed her breathing to be rapid and shallow. She talked incoherently in her sleep. At 10.30 a.m. a rash appeared on the face and limbs consisting of "black spots which rapidly enlarged into blotches." At 2 p.m. the temperature was 102° F. (38.9° C.) and respirations were rapid. A purpuric rash was present on the face, neck, and limbs. There was no neck rigidity. Admission to hospital was requested.

On admission at 6 p.m. her temperature was 100° F. (37.8° C.), pulse imperceptible, and respirations 40. She was conscious and rational and complained only of pain in the right shoulder and weakness. Purpuric blotches and petechial spots were seen on the face, neck, arms, and legs, but not on the trunk. The heart sounds were faint—the rate was 140. The blood pressure was unobtainable. The lungs and abdomen were normal. There was dubious neck rigidity, Kernig's sign was not obtained, and the reflexes were absent.

A diagnosis of fulminating meningococcal septicaemia with adrenal haemorrhages was made, and 10 ml. of adrenal cortical extract was injected intramuscularly. Owing to the peripheral vascular collapse it was impossible to administer this intravenously; nor was it possible to obtain blood for culture and biochemical examination. Immediate preparations were made to set up an intravenous saline infusion and to begin therapy with penicillin and sulphadiazine. At 6.45 p.m., however, 20 hours after the onset of the disease, she died, remaining clear-minded to the end.

Necropsy was performed by Dr. Raeburn 20 hours after death. The body was that of a well-developed girl with an extensive purpuric rash on the face, neck, shoulders, arms, and legs. The body was free. The myocardium was pale, soft, and swollen on section. A few petechiae were seen beneath the endocardium. The entire respiratory tract was intensely congested. The mucosa of the trachea and bronchi was bright red. The lungs were markedly congested and semi-airless; minute haemorrhages could be distinguished in the parenchyma. The whole alimentary tract was congested, with numerous subserous petechiae on the stomach and small intestine. The thyroid gland, pancreas, ovaries, and kidneys were all congested. The adrenals were congested, but there was no gross haemorrhage, and the structure of the glands seemed intact. They were no more strikingly congested than the thyroid, pancreas, and kidneys, and less so than the lungs. The thymus was large and fleshy, weighing 42 g. The leptomeninges of both the brain and the spinal cord were hyperaemic, and there was a little fibrinous exudate in the sulci. The brain substance was hyperaemic and slightly oedematous. Blood obtained from the right ventricle was cultured and a profuse growth of meningococci (Type I) was obtained. The same organism was isolated from a swab taken from the sphenoid sinus.

Histological Examination.—The adrenals showed congestion of the vessels, with a number of minute haemorrhages. The spinal cord exhibited changes typical of leptomeningitis. The thymus showed normal glandular tissue, and the kidneys, pituitary, and thyroid congestion only. The lungs showed intense dilatation and congestion of the capillaries with secondary atelectasis.

Death was considered to be due to fulminating meningococcal septicaemia.

Discussion

Banks and McCartney (1942, 1943) classify fulminating meningococcal septicaemia into an encephalitic type, characterized by mental clouding progressing to coma; an adrenal type with purpuric rashes, peripheral vascular failure, and mental clearness; and a mixed type, having some of the features of the other two. Our cases are examples of the pure adrenal type, and the clinical picture is characteristic and easily recognized. Meningococci were not recovered from Case 2, probably owing to the early administration of penicillin and sulphadiazine.

In neither fatal case was there gross destruction of the adrenal glands, though congestion was seen in both and microscopic haemorrhage in one. Williams (1942) noted the absence of gross adrenal lesions in eight out of 17 clinically typical cases, and suggested that adrenal deficiency might not be an important factor in the pathogenesis of the syndrome.

Kinsman, D'Alonzo, and Russi (1946) describe a condition of "tubular degeneration" occurring in two fatal cases, without adrenal haemorrhages. The cortical cells appeared shrunken and fat globules were absent, so that the "cords" of cells usually seen looked like tubes containing fibrinous debris. They suggest that this condition is the result of adrenal exhaustion due to increased demand for the lipoid hormone during the acute infection, and, further, that irreversible damage has not occurred at this stage.

Banks (1948) states that necropsy material from all his fatal cases showed "significant" adrenal lesions. We were impressed by the dramatic improvement which followed intravenous saline and cortical extract in Case 2. Since there was no dehydration and there had been no vomiting, it is difficult to believe that the infusion of 150 ml. of saline alone accounted for this improvement. We were convinced that the cortical extract was responsible. We agree, therefore, with Banks (1948) that, though toxic and other factors may be concerned, there is justification for regarding acute adrenal deficiency as playing a leading part in the pathogenesis of this syndrome and for treating it accordingly.

The thymus gland was found to be persistent in Case 1 and larger than normal in Case 3. In both cases it was of normal microscopical structure. A similar enlargement and persistence have been recorded by Magnusson (1934) and Holmes and Cowan (1945). The rapid course of the illness makes it evident that the enlargement preceded infection and suggests the existence of a constitutional type with a large thymus and small fragile adrenals in whom resistance to meningococcal infection is lower than normal.

When a clinical diagnosis has been made treatment must be immediately instituted for septicaemia, peripheral circulatory failure, and adrenal insufficiency.

Treatment of the Septicaemia.—The meningococcus is susceptible to sulphonamides and to penicillin. It is advisable to employ both in order to control the septicaemia as rapidly and completely as possible. Any sulphonamide can be used, but, owing to the lower risk of producing renal complications, sulphamezathine is probably the drug of choice. A blood level of 15 mg. per 100 ml. should be maintained. The initial doses should be given intravenously, and for a young adult the dosage should be 4 g. immediately and 2 g. four-hourly until facilities for control by estimation of the blood level are available. Penicillin intramuscularly in full doses should be started immediately. Case 2 received 30,000 units three-hourly, but now that penicillin is more readily available much larger doses should be employed—e.g., 250,000 to 500,000 units immediately, followed by 100,000 units three-hourly. Even with such

doses it is hazardous to increase the time interval between injections, as a constant strongly bacteriostatic blood-penicillin level is essential in so serious an illness.

Peripheral Circulatory Failure.—An intravenous infusion of normal saline should be set up immediately. In acute adrenal deficiency the blood volume is reduced and the blood viscosity increased by loss of sodium and water into the tissues and by excretion into the urine. Logically the infusion should therefore be normal saline rather than plasma or whole blood.

Adrenal Deficiency.—Adrenal cortical extract B.P.C., or one of the proprietary preparations such as eucortone or eschatin, should be given intravenously as soon as possible. The initial dose should be 10 ml., and this should be repeated four-hourly until the systolic blood pressure is maintained above 100 mm. Hg. If the extract is not immediately available, desoxycortone acetate can be used in doses of 10 mg. eight-hourly, intramuscularly. Adrenaline hydrochloride, 3 min. (0.2 ml.) subcutaneously, six-hourly, can be given, but it is of doubtful benefit. Ascorbic acid 500 mg. intravenously, twice daily, may be helpful. The adrenals contain much ascorbic acid, but its function is unknown, and its therapeutic use here is empirical. Vitamin K analogue—menaphthone—one 5-mg. ampoule should be given initially to ensure a normal prothrombin level. The order of treatment should be: (1) begin intramuscular penicillin injections; (2) set up an intravenous drip-infusion of normal saline; (3) begin intravenous sulphamezathine, adrenal cortical extracts, and ascorbic acid via the infusion tubing; and (4) give adrenalin hydrochloride and menaphthone.

Summary

Three cases of fulminating meningococcal septicaemia are described. One of them, a child aged 3, recovered after treatment with penicillin, sulphadiazine, and adrenal cortical extracts.

This condition occurs sporadically as well as during epidemics and presents as a severe illness of sudden onset, with a purpuric rash and profound peripheral circulatory failure. In untreated cases death occurs in 24–36 hours.

At necropsy, adrenal lesions are always found. Acute adrenal deficiency is probably a factor in the fatal outcome.

Diagnosis must be made on clinical grounds. Treatment should be started immediately with penicillin, sulphamezathine, intravenous saline, and adrenal cortical extracts, without awaiting laboratory investigations. If it is begun early enough there is a reasonable chance of recovery without sequelae.

We are indebted to Dr. P. Hamill, under whose care these cases were admitted to hospital, for permission to publish this report and for help and encouragement in its preparation.

The Hospital Savings Association announces that Mr. Thom Denman, its general secretary, retired on March 1. His early experience was in the office of a local authority, then on the passing of the National Insurance Act of 1911 he became clerk to an insurance committee. In 1919, seeking the greater freedom and flexibility of a voluntary organization, he joined the late Dr. Gordon D. of Brighton, in founding and organizing the Sussex Provident Scheme. It was from this scheme that he developed the idea of the H.S.A. He was appointed financial secretary on its incorporation in 1922 and from the first has been responsible for all the financial arrangements. In 1939 he became joint secretary and in 1945 general secretary. His successor will be Mr. C. S. Clarke, who joined the staff in 1931 and has been deputy general secretary since 1946.

NOMOGRAMS FOR SLING AND ASSMANN PSYCHROMETERS

B1

J. B. de V. WEIR, M.A., B.Sc., M.B.

(From the Institute of Physiology, University of Glasgow)

In an annotation in the *Journal* (1948, 1, 989) it was suggested that nomograms for use with the Assmann and the sling or whirling psychrometers might be welcomed, as these are the instruments of choice for the measurement of the hygrometric properties of the atmosphere with scientific accuracy. The accompanying nomograms have been designed accordingly

FIG. 1.—Nomogram for finding the relative humidity of the air from the dry-bulb and wet-bulb readings of a ventilated psychrometer

FIG. 2.—Nomogram for finding the drying capacity or saturation deficiency of the air from the dry-bulb and wet-bulb readings of a ventilated psychrometer.

To use the nomograms a stretched thread or a transparent ruler is placed so as to lie on the readings of the dry-bulb and wet-bulb thermometers; the relative humidity and the saturation deficiency can then be read off the appropriate scales.

The depression of the wet-bulb temperature below the dry-bulb temperature is sensitive to the speed of the air passing over the wet bulb for speeds up to five miles per hour, but is practically the same for all speeds beyond this (Meteorological Office, 1940). Bell and Weir (1947) have produced nomograms suitable for use in calm conditions. Ventilated psychrometers such as the Assmann and the sling psychrometer are so arranged that an air speed past the wet bulb of over five m.p.h. is obtained artificially, and so, being independent of the natural air speed, these instruments give the most reliable results.

The hygrometric properties of the atmosphere are of importance in body-temperature regulation, especially under conditions of stress such as exist in the Tropics, in deep mines, and in operating theatres (Wynne, 1947). They are also of special interest to heating and ventilating engineers and to the textile industry.

[EDITOR'S NOTE.—It has been found impracticable to publish the nomograms here in a size that would make them really useful. They have therefore been separately printed full scale on art paper for those who are interested. Copies may be obtained from the Publishing Manager on application.]

Medical Memoranda

Ligation of the Mandibular (Inferior Dental) Artery

In deep operations on the face and the jaws preliminary ligation of the external carotid artery is not always entirely satisfactory in attaining its objective—that is to say, it does not give one a bloodless field and does not prevent venous and post-operative bleeding from innumerable oozing points; nor does it prevent the formation of a deep haematoma in a closed wound. Admittedly it controls from 50 to 75% of the bleeding, but even a remaining 25% is apt to be not only a great nuisance but a source of danger if it continues post-operatively into the mouth. Particularly is this so in the removal of sections of the mandible involving the ascending ramus.

CASE REPORT

I was faced with this problem recently in a young female patient. X-ray examinations of her lower jaw showed a ragged, eroded cavity in the centre of the bone extending well up into the ascending ramus above the point of entry of the mandibular artery. The bone was distended but there was no surface lesion. It looked malignant, and was getting larger fairly rapidly. (A subsequent pathological report stated that it was a malignant adamantinoma, which is what the clinical evidence and x-ray examination had led us to believe.)

To have obtained good access through the usual curved external incision would have involved an almost certain facial paralysis and a blind groping for the mandibular artery and vein, with a considerable probability of being unable to secure them. It was determined, therefore, to do the major part of the operation from within the mouth, and if possible to ligate the mandibular artery before it entered the lower jaw. I had reason to believe from war experience that this would not only be quite feasible but not too difficult. Search, however, failed to find any record of this ligation having been performed previously. Presumably its short course of an inch (2.5 cm.) or less from the internal maxillary artery to the foramen in the lower jaw has been regarded as inaccessible.

Operative Technique.—Operation was performed on Feb. 25, 1948, under full morphine and hyoscine premedication (Corlette system) and local analgesia (procaine and adrenaline), as follows:

1. Vertical incisions were made in the centre lines of the upper and lower lips to increase the retractability of the angle of the mouth and cheek. This procedure improves visibility and access very considerably and, anatomically and cosmetically, is preferable to a horizontal incision at the angle of the mouth.

2. Insertion of a Davis gag and opening it to the maximum extent produced a dislocation of the jaw, which served to fix it in place and also to bring the inferior dental foramen into the most forward possible position. Most of the operation was then carried out without a gag, but with medial and lateral retraction of the tongue and cheek. No packing was placed in the pharynx; continuous suction was used, and the blood remained a nice bright colour throughout.

3. A vertical incision was made through the muco-periosteum of the jaw; it extended from near the tip of the coronoid process along the crest of the alveolar ridge to the region of the first bicuspid tooth.

4. A short external incision was made along the lower border of the jaw just posterior to the mental foramen.

5. The whole of the periosteum of the jaw was stripped from the bone, except the upper part of the ascending ramus and the region of the inferior dental foramen.

6. With good retraction inwards of the internal pterygoid muscle, focal illumination, and blunt dissection, the artery, vein, and nerve entering the bone were soon located, identified, and isolated.

7. A clamp was placed on the whole bundle, silk ligatures were passed above and below and tied, and division was made on removal of the clamp; there was no sign of haemorrhage, and the jaw became visible on its inner aspect right down to the angle.

8. The ascending ramus was then divided partly with a Gigli saw and partly with bone shears, about $\frac{1}{4}$ in. (1.9 cm.) below the condyle.

9. The anterior end of the bone was next divided by a saw-cut posterior to the mental foramen and the section of jaw removed. The dislocation was then reduced without difficulty. This left a fairly dry cavity lined with periosteum.

The patient's recovery was quite placid and painless. She remembers nothing of the operation, during which she slept motionless. Penicillin was given prophylactically for a few days.

In selected cases of surgery involving the ascending ramus of the jaw this procedure may prove useful. Ligation of the nerve as well as the vessels should be sound practice in view of recent experiments by M. P. Chenilleau (*Int. Abstr. Surg.*, 1948, 86, 351), which showed that ligation of nerve-ends in animals prevented the formation of painful neuromas and also of trophic ulcers, particularly if linen thread was used instead of catgut.

I am indebted to my wife for skilful assistance. She was in fact the first to see the vessels at the foramen and to call my attention to the fact: they were even a little further forward and a little higher up than I had anticipated. I had just by-passed them on the lower side.

It is proposed to submit a fuller account of this case, illustrated by radiographs of the subsequent bone graft, for publication at a later date.

H. P. PICKERILL, C.B.E., M.S., F.R.A.C.S.

Wellington, New Zealand.

Heterotopic Pancreatic Tissue in the Ileum Causing Intussusception

Heterotopic pancreatic tissue in the wall of the ileum is rare; records of only thirteen cases can be found in the literature. Fourteen cases in which the pancreatic tissue was present in a diverticulum from the ileum are also recorded. The details of the ileal-wall cases are scanty, but intussusception occurred in three. I record a further case of intussusception caused by heterotopic pancreatic tissue in the ileum.

CASE REPORT

On Feb. 21, 1947, I was asked by Dr. J. W. Wilson, of Stirling, to see a girl aged 9½. At 2 p.m. that day she had been seized by sudden severe abdominal pain so intense as to cause fainting. The pain, colicky in nature, was felt mostly in the central abdomen and was accompanied by continued vomiting. One year previously she had had a similar but less severe attack which passed off in twenty-four hours. Examination showed slight fullness of the upper abdomen and marked tenderness and slight rigidity in the right side of the abdomen; a mass about the size of an orange was palpable to the right of and just below the umbilicus. Immediate operation was advised and the patient was admitted to Stirling Royal Infirmary.

On opening the abdomen some five hours after the onset of symptoms an ileo-ileal intussusception was found some 3 ft. (0.9 m.) up from the ileo-caecal junction. The intussusception was easily reduced. At the apex of the intussusceptum a well-defined plaque of tissue 2 by 1 cm. and some 2 mm. thick was found on the anti-mesenteric border of the bowel. This clearly had excited the intussusception. The plaque was resected, but so much narrowing of the

bowel resulted from suture that it was thought wiser to resect a small segment of the ileum. This was done, and the abdomen was closed after an end-to-end anastomosis. Recovery was uneventful.

Pathological Report.—Dr. W. W. Park, of the Royal College of Physicians Laboratory, Edinburgh, supplied the following report on the specimen: "The specimen consists of a piece of compressed tissue, 2 by 1 cm. Microscopical examination shows: (1) Large masses of well-developed glandular tissue (Fig. 1) lying closely adjacent to the gut wall, and in places growing up to and even into the muscular layers. (2) The tissue is highly differentiated into acinar structures with well-formed ducts and ductules (Fig. 2). The

FIG. 1.—Glandular tissue. (×150.)

FIG. 2.—Glandular tissue. (×400.)

cell type is uniform and moderately large, and there are no mitoses. There is no evidence of malignancy. (3) This type of growth is regarded as a developmental error, hamartomatous in type. Conventionally, tissue of this nature is designated heterotopic pancreatic tissue, although in this case, where there is no sign of any islet tissue, it would be more correct to regard it as non-specific developmental overgrowth."

I am indebted to Mr. Stanley Hay, Dr. Park's technical supervisor for the photomicrographs.

Reviews

CARDIOGRAPHY

Cardiography. By William Evans, M.D., D.Sc., F.R.C.P. (Pp. 132; illustrated 25s.) London: Butterworth and Co. (Publishers). 1948.

This book gives a fully illustrated account of electrocardiographic abnormalities and of phonocardiographic tracings. Unfortunately the author dismisses the "V" unipolar precordial and limb leads as vectors (p. 2), with which in fact they have nothing at all to do (V stands for voltage). Consequently the reader will learn nothing of the principles upon which modern cardiography is based, nor of the effect upon the cardiogram of rotation of the heart on any of its axes. Left bundle branch block is described as showing "L.A.D." The QRS complexes are wide with the T wave written in the opposite direction to the QRS" (Fig. 54, etc.). This discordant type of left branch block is due merely to a horizontal position of the heart. Concordant curves, due to a vertical position, are classified as bundle branch block, though in Fig. 118 the single precordial lead given makes it obvious that the lesion is left-sided. The author includes auricular flutter among the lower ranges of the auricular tachycardias, in which the auricular rate is stated to vary from 250 to 500 a minute. If the ventricular rate is less than 200, and the extra P waves cannot be made out, they are assumed to be buried in the QRS. In auricular flutter, however, the response to carotid sinus pressure is different and the existence of a circulating wave was proved by Lewis. The author does not mention the recent suggestion that some auricular paroxysms may be due to a circulating wave with a slower rate than in flutter because the A-V node is involved in the orbit. He gives a good account of the cardiographic changes in acute pericarditis, but does not say that pathological Q waves are absent, nor why this must be so. The section on cardiac ischaemia contains much wisdom. Some of the interpretations are open to question. Fig. 23 would seem to show premature ventricular systoles; the auricular rhythm is regular and the P waves are all upright. Fig. 132 suggests a septal infarction. Q waves are not found in lead I in uncomplicated left branch block, and the T wave is "domed." Precordial leads would have helped. It is difficult to understand why the diagnosis of 2:1 heart block in Fig. 147 is rejected. Among other things the form of the T waves in lead II would be most peculiar if P were not summated with them. But these are small blemishes in a book in which the illustrations are uniformly good and well produced, and to anyone content with the older conceptions this section can be recommended as a straightforward and clearly expressed account of cardiographic abnormalities.

Sound tracings were used by Lewis forty years ago, but since then have not attracted much attention in this country. Different types of recording instruments give differing results, and there is no agreement yet on which is the more accurate. In this section the author shows records obtained with a string galvanometer and a glass rod of various additional heart sounds and of cardiac murmurs. The records are very clear and the descriptions easy to follow, but it is rather startling to learn in Fig. 192 of an inaudible murmur.

RADIOTHERAPY

The Treatment of Malignant Disease by Radium and X-rays. By Ralston Paterson, M.C., M.D., F.R.C.S.Ed., D.M.R.E., F.F.R. Being a Practice of Radiotherapy. (Pp. 622; illustrated. 52 ss.) London: Edward Arnold. 1948.

Radiotherapy is a relatively new branch of medicine requiring an acquaintance with physics and biophysics which is unnecessary in other medical work. Physicians and surgeons tend to regard the radiotherapist as a kind of technician, and this indeed he must be; but he must also be a clinician who, like the general physician and the general practitioner, is concerned with all regions of the body and with problems of

nutrition, relief of pain, nursing, and the innumerable ways in which cancer and the metabolism of the individual are linked. The reader of Dr. Paterson's textbook on radiotherapy gains an appreciation of these two sides of the subject—a technical knowledge of the accurate administration of radiation and insight into its effects, and also the knowledge of patients necessary to every true doctor. The author considers the technical side in great detail, but the clinical aspects form a background against which the technical points may be appreciated by radiotherapists. No one without an immense knowledge and experience of cancer treatment could have attempted such a work. While Paterson is the author of the book, he refers also to the team at the Holt Radium Institute whose work has made it possible for him to write it. He is clearly the inspiration of this team and the architect of an elaborate, extensive, and efficient organization which has already published many papers and, in the last two years, accounts of the results achieved by the methods he describes here and a book on radium dosage.

Having decided from the experience of himself and others what doses of radiation he thinks are necessary to destroy cancers and to help patients in whom they cannot be destroyed, Paterson has given details of how to administer those doses, bearing in mind the technical and clinical difficulties. He has been helped with certain chapters by other authorities. Windeyer and Roberts contribute a chapter on radium beam work; Levitt discusses the treatment of blood dyscrasias; Margaret Tod helps with the chapters on reticulo-endothelial and gynaecological conditions; Dobbie teaches us a great deal about beam direction and field selection. Dr. Edith Paterson's review of the biological effects of radiation is excellent but seems to be insufficiently related to the rest of the book. Jefferson's article on tumours of the central nervous system is short but very interesting. The physics is capably dealt with by Meredith.

In his introduction the author prepares us for an account of Manchester methods based on Manchester ideas. While this gives force to the book it detracts from its value as a textbook. Calibration of apparatus, details of organization, equipment and staffing of centres of radiotherapy, the provision of isodose curves, radium charts, and lucid details in connexion with the nursing of patients are all desirable features, but some omissions strike one. For instance, the use of differentially loaded radium needles for implants and the use of radon ointment in treating necrosis are important technical advances. The heavy dosage given to the spinal cord in treating pharyngeal cancer, the insistence on treating the whole penile shaft for all penile cancer, and the dogmatic attitude to certain as yet unsettled principles of radiation biology are a few of the points one would like to argue with the author. The chapter on new radiotherapeutic agents, however, is balanced and clear.

Every radiotherapist will find the book readable and exceedingly useful. It is important that those with little experience should, as indicated by the author, realize that it is a statement of present-day Manchester principles and methods only. Radiotherapy is still a developing subject.

FRANK ELLIS.

SWISS OBSTETRICS

Lehrbuch der Geburtshilfe. By Th. Koller. Volumes 1 and 2. (Pp. 613 Vol. 1 and 1,323 Vol. 2. 110 Swiss francs.) Basle: Verlag von S. Karger. 1948.

This two-volume textbook of obstetrics forms part of "The System of Obstetrics and Gynaecology," written under the direction of Professors Anderes, Guggisberg, and Koller, of Switzerland. The publishers have maintained the exceptionally high standard for which they are well known on the Continent. The print and paper will be examined with envy by British medical authors. The excellent illustrations are derived in the main from photographs and photomicrographs, and, together with the line drawings, are a striking feature of the book.

The subject matter is of some interest, for it follows the traditional German style and contains a wealth of theory at the expense of clinical examination and operative technique. It is quite out of keeping with modern American and British

textbooks. The author has paid very little attention to original work carried out in America or Britain. This neglect is particularly striking in the chapter on implantation, and an outstanding omission is any reference to the important contributions of Caldwell and Malloy. For a modern textbook the author has emphasized puerperal sepsis too much and described foetal abnormalities in too great detail. As a standard textbook for Swiss students and practitioners the book will be held in esteem and perhaps with affection, but it is unlikely to receive much attention in either America or Great Britain.

WILFRED SHAW.

A GUIDE TO CHEMOTHERAPY

A-B-C's of Sulfonamide and Antibiotic Therapy. By Perrin H. Long, M.D., F.R.C.P. (Pp. 231. 17s. 6d.) Philadelphia and London: W. B. Saunders Company. 1948.

In this little book the author first discusses general principles and methods of administration of sulphonamides, penicillin, and streptomycin, and then the principal diseases and conditions, in alphabetical order from "abscess" to "yaws," for which they are indicated. His clear and dogmatic instructions include brief references to other forms of treatment and frequent warnings against undue reliance on chemotherapy when, for instance, surgery is also required, and against giving these drugs without adequate reason on the off-chance that they may do good.

Noteworthy features are the full discussions on syphilis and tuberculosis, the heroic system of dosage advocated for subacute bacterial endocarditis (2-hourly injections for six weeks), and the repeated warnings, because of the danger of sensitization, given against local application. He considers that the local treatment of ulcers, burns, and blepharitis with either sulphonamides or penicillin is inadvisable for this reason, which seems unfortunate. He advises the use of penicillin for controlling peritonitis due to perforating wounds but not for that produced by appendicitis, a distinction for which the reasons are not quite clear. Although in a few instances everyone may not agree with the instructions given, this book should be a useful and handy guide to the practitioner.

L. P. GARROD.

MINOR SURGERY IN GERMANY

Kleine Chirurgie. By Professor Hans Kurtzahn, revised by W. Heyn. 12th edition. (Pp. 496. M.17.50.) Berlin: Urban und Schwarzenberg. 1948.

Perusal of this book makes one feel rather sad. Here is the 12th edition of a very popular German book on minor surgery rather poorly produced and very much out of date. Though this edition has the year 1948 on the title page it might almost as well have been published ten years ago. It contains much useful information on fractures, minor operations, and the like, but shows little evidence that the far-reaching new discoveries of the last few years have reached the medical profession in Germany. It is not necessary to read far to find this out. The sulphonamides are said to be useful, but no dosage is given, and the author says of their use in erysipelas that no definite judgment can be given on their efficacy. An account of penicillin occupies thirteen lines; it is described as a drug recently developed by the Americans; about its value we are told that we must wait for a future edition for a conclusive estimation of its efficacy. No description of dosage is given nor of methods of administering it. The author does not mention it in discussing the treatment of septic infection of the fingers, or that of carbuncle, for which extirpation is said to be the best treatment. He describes old-fashioned remedies for the treatment of burns and refers to therapy by tannic acid as a recent innovation. (It was introduced in 1925.) Tannic acid is specially recommended for the treatment of burnt fingers and hands. All the recent advances in the treatment of burns are ignored. And so we could go on. In this country the chief use of this book should be to stimulate surgeons to help their brethren in Germany to learn of the wonderful new remedies of which they know so little.

ZACHARY COPE.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Proceedings of the Annual Meeting, 1948. British Medical Association. (Pp. 415. 35s., postage 1s. 3d. extra.) London: Butterworth. 1949.

The collected papers read at the Association Meeting in Cambridge last June.

Papers on Psycho-analysis. By E. Jones, M.D., F.R.C.P. 5th ed. (Pp. 504. 31s. 6d.) London: Baillière, Tindall and Cox. 1948.

In this edition nine recent papers replace some older ones.

Arterial Hypertension. By D. Ayman, M.D. (Pp. 91. 12s. 6d.) New York and London: Geoffrey Cumberlege. 1948.

A monograph reprinted from the *Oxford Loose-Leaf Medicine*.

Death in Clairvoyance. By J. Bell. (Pp. 244. 9s. 6d.) London: Longmans, Green and Co. 1949

A detective story.

Juvenile Rheumatism. By G. E. M. Scott, M.B., L.R.C.P.Ed., L.R.F.P.S. (Pp. 163. 25s.) Melbourne: W. Ramsay, Ltd. 1948.

A review of the author's experience.

The Train. By V. Panova. (Pp. 252. 9s. 6d.) London: Putnam and Co., Ltd. 1948.

A novel, translated from the Russian, about a hospital train in the U.S.S.R. during the war.

Some Common Psychosomatic Manifestations. By J. B. Murray, M.A., M.D., M.R.C.P. (Pp. 101. 7s. 6d.) London: Geoffrey Cumberlege. 1949.

An account of effort syndrome and the "low-back syndrome."

Our Plundered Planet. By F. Osborn. (Pp. 192. 10s. 6d.) London: Faber and Faber. 1949.

The author's theme is the conservation of soil fertility and the neglect of this in many countries.

Guiding Human Misfits. By Alexandra Adler, M.D. (Pp. 114. 7s. 6d.) London: Faber and Faber. 1949.

An account of the writer's experience; intended for both medical practitioners and laymen.

Hemolysis and Related Phenomena. By E. Ponder. (Pp. 398. 50s.) London: J. and A. Churchill. 1948.

A monograph on the structure and haemolysis of mammalian red cells.

Topics in Physical Chemistry. By W. M. Clark, Ph.D., Sc.D. (Pp. 738. 44s.) London: Baillière, Tindall and Cox. 1948.

A textbook for undergraduate students.

The Belsen Trial. Edited by R. Phillips, M.C., M.A., B.C.L. (Pp. 749. 30s.) London: William Hodge. 1949.

A verbatim record of the trial.

Aids to Biochemistry. By E. A. Cooper, D.Sc., F.R.I.C., A.R.C.S., and S. D. Nicholas, B.A., A.R.I.C. 4th ed. (Pp. 244. 5s.) London: Baillière, Tindall and Cox. 1948.

The book has been extensively revised for this edition.

The Mystery of Birth. By J. Oldfield, T.D., D.C.L., M.A., M.R.C.S., L.R.C.P. (Pp. 208. 12s. 6d.) London: Rider. 1948.

Discussion of many topics related to birth, sex, and heredity.

Outline of Arabic Contributions to Medicine and the Allied Sciences. By A. A. Khairallah, B.A., M.D., F.A.C.S. (Pp. 228. S2.50.) Beirut: American Press. 1946.

Annotated quotations from Arabic works; in English.

Energy and Matter. By R. L. Worrall, M.B., Ch.M., D.P.H. (Pp. 144. 10s. 6d.) London: Staples Press. 1948.

A description in plain language of some of the concepts of modern physics.

Anaemia Problems in Rheumatoid Arthritis. By F. Nilsson. (Pp. 193. No price.) Uppsala: Appelbergs. 1948.

A monograph with references.

TRANSMISSION OF SARCOMA
BY DRIED TISSUE

Cancer is so different from microbial infections that most pathologists are reluctant to accept the notion that a virus can be its cause. No one any longer disputes that some tumours are caused by viruses: first, there are various sarcomata and other connective tissue tumours of fowls; there is an adeno-carcinoma of frogs; there is Shope's papilloma of cottontail rabbits and the cancers derived from it; and finally there is Bittner's milk factor, which plays an essential part in causing mammary cancers in inbred mice and has all the properties of a virus. Towards these virus tumours pathologists take up one of two attitudes. Most of them regard them as exceptional growths, zoological curiosities. They feel that all cancers need not have the same aetiology: some are induced by carcinogenic hydrocarbons, some by x rays and other physical agents, some by parasitic worms, most by as yet undefined causes—and a small minority by viruses. The other, much smaller, school of thought, led by Rous in America and Gye in this country, emphasizes an important difference between the part played in tumour causation by a virus and by hydrocarbons and other agents. The hydrocarbon determines the onset of the tumour, but is then no longer essential for its continued growth, while the virus remains in the cancer cell and is apparently the driving force constantly imposing upon it its malignant conduct. The Rous fowl sarcoma, in Boycott's words, "has been provided for our learning and pushed under our noses by Providence," and "we should not be too shy of drawing conclusions from such . . . examples."¹

The core of the whole argument is this: Are the filterable tumours things apart, or are they essentially the same as other tumours, differing only in some quantitative manner, so that our techniques just fail (as they sometimes fail even with fowl tumours) to reveal a continuing cause separable from the living cell? In an Imperial Cancer Research Fund Lecture delivered at the Royal College of Surgeons on March 22 and published as the opening paper in this issue, Professor W. E. Gye, F.R.S., has sketched the historical background of this side of cancer research. He has shown how attempts to find a continuing cause for malignant growth within the cells of most cancers have failed again and again, until most workers believe that no such separate entity exists and that cancerous growth is nothing but abnormal behaviour imposed permanently upon the cell by some event in the past. He then puts forward evidence, even finding clues in work done as far back as 1907, that the propagation of experimental tumours need not always depend on the transplantation of intact cells. The malignant transformation of the stroma of

transplanted carcinomata has been long known; one possible explanation has been the transfer of an agent from the malignant cells to those adjacent to it. Successful transplantation with tumour tissue frozen at -10°C has been known for forty years and has been attributed to the cancer cells' tenacity of life. Similar results can be achieved with tumours frozen at -79°C ., but this fact is not nearly so remarkable as the results obtained at -10°C . At that temperature, Professor Gye points out, water crystallizes out but salts do not, and the cell is in fact pickled in strong brine. More recent work shows that suspensions of tumour cells survive in 40% glycerin or 40% glucose.

In contrast to all this are normal embryonic cells; their viability can be tested, for they continue to live as grafts in individuals of a similar inbred stock. It turns out that they are not remarkably tenacious of life, for they die after less than an hour at -79°C . Here are a number of straws pointing one way; but we lack certainty. It may be that cancer cells can withstand freezing, pickling, and other maltreatments which no ordinary cell would be expected to stand. Though histological study of long-frozen tissue reveals no intact cell, there is the chance that an odd cell has eluded observation, and, after all, trypanosomes can survive at -76°C .

But now Professor Gye and his colleagues take a step further, for they have transmitted three mouse sarcomata by means of dried tissues. It is far harder to believe in the survival of dried mammalian cells than of those merely pickled or frozen. It is known that bacterial cells can survive drying indefinitely, but their organization is very different from that of the cell of a mammal. Transmission of the Rous sarcoma by dried tissue is, along with filterability, the convincing piece of evidence that the transmitting agent is a virus. Two things have made possible the new success in a field where failure has for years beset many investigators. First, Dr. James Craigie has improved the technique of drying by the use of an apparatus of which a description is reported to be in the press. Secondly, it has been found, very surprisingly, that tumour tissue which has been frozen for some time and then dried can still reproduce a tumour on injection, while tissue dried while fresh will be inactive or at any rate much less potent. Professor Gye does not go deeply into the reason for this remarkable finding, though he suggests the possibility of gradual denaturation of an inhibitor at low temperatures. From all this work he concludes, "It is no longer justifiable to put the . . . filterable tumours of chickens in a separate class. . . . This work has now brought tumours of mice . . . into the same class. They have a continuing cause, and . . . probably it is viral in nature."

The question will be asked, "Do the facts justify this most important conclusion?" While it is probably the right one, the issues at stake are so important that the evidence must be completely convincing. It is to be hoped that future developments in this work will provide the answer to three questions: Is it reasonably certain that frozen, pickled, and above all dried tumour tissue does not contain any living mammalian cells at all? Secondly, are the results with these three sarcomata applicable to sarcomata generally? Two of the three which have now been dried

¹ *Proc. R. Soc. Med.*, 1928, 22, 55.

are sarcomata derived from malignant transformation of the stroma of epithelial tumours, and therefore perhaps more likely than the average to yield evidence of a cause separable from the cells. The third is, however, a sarcoma induced by methylcholanthrene; there is, therefore, particular significance if evidence of a virus can be found in it. The finding of a single mouse sarcoma resistant to drying would not be fundamentally important—it could be dismissed as yet another zoological curiosity. Discovery of a general principle applicable to many or all mouse sarcomata would be another story. Are three successfully dried tumours so very much better than one? Thirdly, can epithelial tumours, too, be transmitted with dried tissue? It will be recalled that as yet no carcinoma of the fowl has been successfully dried or filtered—most of them cannot even be transplanted.

Suppose the answers to these three questions turn out affirmatively and we can safely accept the conclusion that tumours in general can be propagated in the absence of viable tumour cells, where does this lead? It leads certainly to the biggest advance in cancer research for many years. It means that of current theories of the nature of cancer some 90% can be quietly relegated to the waste-paper basket, leaving investigators free to concentrate on a much more limited field through which certain obvious paths are clearly indicated. The new work does not, of course, throw light on another controversial question briefly mentioned at the end of Professor Gye's lecture—are tumour viruses of intrinsic or extrinsic origin?

Professor Gye is due to retire this summer from the directorship of the laboratories of the Imperial Cancer Research Fund. His successor, Dr. James Craigie, F.R.S., much of whose work has lain hitherto in fields other than cancer, has been a very active partner in the recent research and will be able with his colleagues to continue the work of opening up this fruitful discovery.

DELAYED ADMISSION TO HOSPITAL

About a year ago we published an article by Dr. Richard Asher on the dangers of going to bed. It will not be long before we are asked to publish an article on the dangers of not going to bed, if the present difficulties experienced by general practitioners all over the country in securing admission of urgent cases to hospital continue. The situation has become so serious in London, for example, that the Local Medical Committee, having considered a confidential report of a meeting at the Ministry of Health, passed a resolution deploring such delay and stating the deep concern of the Committee about "reports which reach it of many patients who have died whose lives might have been saved had energetic action been taken to secure medical and nursing attention for them at the time when practitioners endeavoured to obtain their admission to hospital." One of the cases that prompted the Local Medical Committee for London to take action was that of a man with chronic tuberculosis suffering from retention of urine. When the medical man in charge of this case asked the Emergency Bed Service to see that the patient

was admitted for the treatment of retention of urine he was told that the E.B.S. could not do this because tuberculous cases were the responsibility of the tuberculosis officer of the appropriate hospital board. The doctor, less concerned with administrative finesse than with the welfare of his patient, refused to accept this decision, and so the E.B.S. referred the matter to a medical officer of the Regional Board, who "confirmed that this was a case for the tuberculosis officer and not one that could be forced into hospital regardless of the tuberculosis, as a matter of life and death." The E.B.S. then inquired whether the patient's local hospital would admit him and was once more met with the objection that the matter should be referred to the tuberculosis officer. The doctor in charge of the case finally found a hospital in which the patient could be treated. A correspondent informs us that at 9 o'clock one evening he asked the E.B.S. to arrange for the admission of a patient with a perforated duodenal ulcer. At midnight he was informed that 10 hospitals had been tried but that no bed was available. He visited his patient twice during the night, and when the unfortunate man was finally admitted at 10 a.m. the next morning he was in a bad condition. Our correspondent adds: "I have been in general practice for 28 years and have never had before July 5, 1948, an experience of this kind." It appears that these are not isolated cases but that the difficulty of getting acute cases into hospital is being experienced by practitioners throughout the country. It is impossible to estimate the size of the problem, but necessary to emphasize that it exists. It is indeed a paradox that a hospital service available for the whole community under the National Health Service Act should in many cases fail at the point where hospital treatment may be a matter of life or death. If this sort of thing had happened before July 5, 1948, it would have been called a scandal and attributed to the faulty organization of the hospital services. There are probably many factors at work which make it difficult to get patients into hospital, but the principal obstacle is that no one now has the authority to insist that an acutely ill patient is immediately admitted to hospital.

From the time of Queen Elizabeth to July, 1948, the destitute sick were in the privileged position of having beds available for hospital treatment. Under the Local Government Act of 1929 local authorities were allowed by permission of the Ministry of Health to appropriate poor law hospitals as public health hospitals, and as a result a municipal hospital service evolved, the outstanding example of which was that under the control of the London County Council. Under the Poor Law the Relieving Officer had the authority to request admission to a poor law hospital of anyone coming under the designation of destitute sick or urgently ill. The Ministry of Health made it a condition for appropriation under the Act of 1929 that the public health or municipal hospitals should incur the same obligation as under the Poor Law to admit urgent cases, and the Relieving Officer was given the responsibility of insisting upon the admission of an urgent case into the municipal hospital. Under the N.H.S. Acts no one below the Minister of Health has the power to require a hospital to admit a sick person. So we have the curious situation in which a privilege

enjoyed by the destitute sick since the time of Queen Elizabeth till July 5, 1948, is now not available to them in a universal hospital service open to all. In relation to the needs of the acute sick the State Hospital Service in London is less efficient than the hospital service previously administered by the London County Council. If the Minister of Health is to fulfil his promises to the public it is imperative that he should see that the old obligation to admit acute cases is restored—and quickly.

It is true that the hospital service generally is suffering from a grave shortage of nurses, reflected in the fact that wards have had to be closed. It is possible that more persons are now seeking hospital treatment, but it is also true that before July, 1948, any hospital, however hard-pressed, always managed to find room for someone in need of life-saving medical or surgical treatment. In London an Emergency Bed Service was established in 1938 to give the practitioner immediate information on the availability of beds. The E.B.S. has not the authority to compel admission. No doubt it is now hard-pressed with requests, but it is permissible to question whether conditions allow it to operate at full efficiency. Practitioners complain that the E.B.S. does not have at any one moment an up-to-date statement of bed vacancies in London. They complain, too, that during the evening and night hours the E.B.S. tends to be of little use. In other words its service seems to be least efficient at the time when the general practitioner experiences the greatest difficulty in securing admission for acutely ill patients. Another possible cause of delay is the establishment of urgency. Any doctor may make a mistake in diagnosis, but the establishment of urgency cannot be done by a clerk who takes down over the telephone details of the frequency of pulse and respiration and of temperature. The place to establish urgency should be at the hospital, and until he or she gets there the patient should be given the benefit of the doubt. But the urgent need is for the quick re-establishment of authority to secure the immediate admission into a State hospital of an acutely ill person.

HOW OFTEN ARE WE ILL?

With the introduction of the National Health Insurance Act of 1911 it was held that valuable records for research would accumulate from the doctors' certificates of incapacity. In fact extremely little was ever done with this potential source of information on the incidence of illness in the working population except, later, in Scotland, where the Department of Health, with a smaller and more manageable number of records, published valuable analyses annually for several years before the war of 1939-45. In England and Wales brief references to the frequency of different diagnoses were for a time made in the annual reports of the Chief Medical Officer of the Ministry of Health, and important pioneer studies of sickness in particular industries, based upon insurance certificates, were issued by the Industrial Health Research Board. No analysis was ever made of the full national records, and it was frequently argued that the diagnoses were not sufficiently accurate to justify such a task. Such arguments

might equally well have applied to the analysis of the early death certificates of 100 years ago—some, no doubt, would say of to-day, too. But it is only through the continual use of the death records as a measuring rod in public health and preventive medicine that the certifying doctor has come to realize the importance of as accurate a diagnosis as he or she can give.

If sickness certificates are similarly valuable measures of the state of the public health—and it is known that they are being analysed for that purpose—there is no reason to doubt that the general practitioner will co-operate, as in registering deaths, by giving as precise a diagnosis as is possible. The system, too, has one great advantage to the busy doctor. Most requests, or demands, for statistics to-day inevitably mean yet another form to fill in. Under the National Insurance Scheme the certificate of sickness has already to be provided, and statistics of the "nature of the illness" suffered by the population and the frequency of different illnesses will merely come out as a by-product. Thus the only plea made by Dr. A. Massey, the Chief Medical Officer to the Ministry of National Insurance, in outlining the Ministry's plans in a statement published in this week's *Supplement* is for an accurate diagnostic statement—except, he recognizes, in the few cases where in the interests of the patient it cannot be done.

In this new study of morbidity the final medical certificate is the one to be used. The Ministry foresees from a working population approaching 25 millions some 7 million claims for sickness benefit a year and about three-quarters of a million claims for industrial injury benefit. It would be very wasteful of man-power and energy to analyse these huge numbers, and in accordance with modern statistical thought it is proposed to take appropriate samples. Every claim to benefit under the Acts, made in the first instance to a local office in any part of the country, has to pass promptly to the Ministry's vast record office in Newcastle. Here the claimant's "insured state" is checked and the appropriate reply returned to the local office. At some point in the ceaseless flow of these documents through the Newcastle office the final medical certificates must day by day be tapped and a representative sample drawn off. The data will then be analysed by means of punched cards and mechanical sorting to give particulars of the illnesses experienced by men and women of different ages, employed in different jobs, and living in different localities. Different times of the year are not mentioned, but this, one may hope, will also be brought into account. Short sicknesses will, of course, be seldom included, since often no claims for these can be made. Such sickness statistics, too, will present many other difficulties in interpretation. For instance, it is very unlikely that persons in the upper social classes will trouble to claim benefit at all when they are ill for a short time; thus their sickness experience will be understated, perhaps quite considerably. Until the next census—due in 1951—the numbers of persons at risk in local areas and in different occupations will be unknown, so that the required sickness rates will be lacking and only those decidedly second-best indices—proportional rates—can be calculated. But in spite of imperfections and difficulties—some merely temporary—the collection and analysis of these morbidity data, which started on Jan. 1

this year, are clearly well worth while—at the very least on the experimental basis on which Dr. Massey places them. The results of the experiment will be awaited with interest.

CHILDREN'S CARDIAC CLINICS

Cardiac clinics to which children suspected of heart disease can be referred for an accurate assessment of their true condition serve a most useful purpose. In a paper appearing elsewhere in this issue Dr. R. Kemball Price describes the working of such a clinic during its first eighteen months and points out not only how it helps the individual child but also how it aids the accumulation of knowledge of heart disease. "Innocent" or "functional" murmurs are particularly common in children, and unless their nature is recognized there is a serious danger that a child's activities may be unnecessarily curtailed, with the development of a cardiac neurosis as a possible result. Further, it is too infrequently realized that most children with inactive rheumatic heart disease and acyanotic congenital heart disease need not lead restricted lives.

Unless active rheumatic infection is present children with minor lesions of rheumatic heart disease have no symptoms, and they suffer no ill effects from being allowed to lead a full, normal life. In the case of the rheumatic child, as of the child with a healthy heart and a functional murmur, unnecessary inactivity may easily lead to needless cardiac invalidism. In fact, of Dr. Kemball Price's first 200 cases 96 had already had their activities restricted on medical advice before being seen at the clinic, and in only 15 was such restriction found necessary. Thus 81 children of the 200 referred to the clinic had suffered needless and unhealthy limitation of their activities. It is equally important that when rest is indicated children's lives must be suitably rearranged, and it is noteworthy that of the 37 children found to have rheumatic heart disease 6 had active rheumatism. While the clinic will not often find it necessary to limit the activities of a child with inactive rheumatic heart disease there is a very important service to the patient which it should perform—that is to advise on suitable occupations. As Dr. Price points out, it is difficult for a man in his thirties to change from manual work to something less strenuous, but it is relatively simple to select a sedentary occupation at the time of leaving school.

Children's cardiac clinics can be expected to provide new information on the incidence of organic heart disease, on "innocent" murmurs, audible third heart sounds, and other abnormalities. Dr. Price, for instance, found more cases of congenital than of rheumatic heart disease. While no closely comparable figures are available for large cities in this country there can be little doubt that in a completely urban area there would be a far larger proportion of children with rheumatic heart disease. This is certainly so in the United States, where, for example, Weiss¹ in Louisville found 69% of all organic heart disease in children to be rheumatic in origin, and Rauh² in

Cincinnati reported a figure of 55%. In neither of these areas is rheumatic fever regarded as prevalent. There has been and still is considerable difference of opinion about the incidence of uncomplicated congenital pulmonary stenosis, perhaps the most extreme view being that of Taussig,³ who considers it one of the rarest types of congenital heart disease. However, in Dr. Price's series physical signs suggesting this diagnosis were common.

Much useful information can be obtained by keeping these children under close observation for many years. This will provide not only a check on the accuracy of the original diagnosis but also information, which at present is lacking, about the disappearance of the "innocent" murmur, so much less commonly found in adults than in children. In addition there is still much to learn about the prognosis of both congenital and rheumatic heart disease. In the case of the latter the results of some long-term studies similar to those envisaged at Brighton by Price are now available. For instance, Ash⁴ has reported from Philadelphia the follow-up of 547 children for 16 years after the onset of the rheumatic infection. Of the 318 children with signs of heart disease at the end of the initial attack 42% had died within ten years; but on the other hand 30 of the children had lost all signs of cardiac abnormality. Of the 219 children with no clinical evidence of heart disease after the first attack only 5% died of heart disease in the 10-year period, and over three-quarters continued to have no abnormal signs. Nearly a quarter of all the children included in this study died of rheumatic infection within 10 years of the onset. Wilson and Lubschez⁵ in New York have carried their survey further having followed up 89% of 1,042 rheumatic children to an average of 14.8 years. Their results were rather better than those of Ash, since only 194 of the patients died of heart disease during the period of observation. Wilson and Lubschez calculate from their figures that a child affected with rheumatic fever has four chances out of five of living for 15 years after the onset, and a one-in-twenty chance of surviving to the age of 40.

Many more such observations as these from different regions are clearly desirable, and there is a need for similar studies of congenital heart disease now that operative treatment is available for some malformations. All too little is known of the natural history of congenital heart disease yet such knowledge is essential for the proper assessment of the risks of operation compared with those inherent in the defect itself.

EXOGENOUS HAEMOCHROMATOSIS

The term haemochromatosis, or "bronzed diabetes," normally calls to mind a rare and little understood condition in which large quantities of iron are deposited in the tissues—notably the skin, liver, pancreas, and abdominal lymph glands, though few organs escape. Varyingly ascribed to an inborn error of metabolism,¹ to copper poisoning,² and more recently to some nutritional deficiency,³ it affects males 20 times as frequently as females and is commonest between the ages of 45 and 55. The reasons why iron should accumulate in the body are not known, which is not surprising in view of the lack of information about the normal metabolism of iron. Until recently, for example, it was believed that iron was absorbed by the small bowel and excreted by

⁵ *J. Amer. med. Ass.*, 1948, 138, 794.

the colon and, in very small amounts, in the urine and bile. This belief is no longer tenable, since it is now clear that iron in the faeces represents merely the unabsorbed residue of the food iron. Recent work⁴ appears to show that the intestinal mucosa in some way controls the absorption of iron according to the needs of the body. Apart from loss of blood—e.g., by menstruation—there is no way in which iron can be eliminated in appreciable quantity,⁵ and this may help to explain why "endogenous" haemochromatosis is so much commoner in males.

Many unsuccessful attempts have been made to produce haemochromatosis in animals by the administration of large quantities of iron. Polson⁶ gave large amounts of dialysed iron subcutaneously or intraperitoneally to rabbits over periods of several years, and despite the accumulation of enormous quantities of iron in the liver no fibrotic changes occurred in this organ or in the pancreas. Cappell⁷ injected colloidal iron intravenously in mice and found that no ill effects resulted from massive deposition of iron in the liver cells. Nothing analogous to the lesions of haemochromatosis in man was seen even when very large amounts of iron were administered over long periods.

Interesting and important as these investigations were, they did not seem to have much direct application to man. At that time injection of iron was regarded as dangerous (despite the large quantities which Cappell was able to use experimentally), and the amounts given were so small that it was unlikely they could influence haemoglobin production, let alone produce haemochromatosis. However, the recent use of iron in a form which can be given intravenously in large quantity^{8,9} has reopened the question of whether haemochromatosis is a risk of such therapy. The amount of iron required to restore the haemoglobin to normal in a case of iron-deficiency anaemia with a haemoglobin of 50% is about 1.5 g., while the accumulation of iron in cases of haemochromatosis may amount to 25–50 g. It would seem, therefore, that the risk is not great, provided that excessive amounts of iron are not given and that the method is not used in cases of anaemia in which there is no iron deficiency and utilization of the iron to form haemoglobin is not possible.

Iron is administered parenterally in a less obvious form when blood transfusions are given. One pint of blood contains approximately 250 mg. of iron, so that repeated transfusion of patients who have no external blood loss, particularly those with aplastic anaemia, may introduce into the body large quantities of iron. It is not unknown for such patients to have received 100 or more pints of blood, representing a total of at least 25 g. of iron, which is as much as may be found in cases of naturally occurring haemochromatosis. Schwartz and Blumenthal¹⁰ describe five such cases in which certain features of haemochromatosis appeared, and they mention eight others previously reported in the literature. In only two out of the thirteen was clinical diabetes present, but in nine there was obvious enlargement of the liver and in twelve some degree of fibrosis was found at biopsy or necropsy. It is difficult to assess the relative importance of the primary disease and the giving of blood in producing these changes, which seem to have been relatively mild. Some haemosiderosis appears to be inevitable when there is parenteral administration of iron, but whether true haemochromatosis, in the sense of pancreatic and hepatic fibrosis and eventual failure, results

from this alone and is a real risk of such treatment remains uncertain. Some further investigation would be of value now that massive blood transfusion and parenteral iron administration have both become common forms of treatment.

CANCER MORBIDITY

Large-scale studies of the incidence of cancer and of the survival rate are scarce. It is over twenty years since the Ministry of Health published the findings of an inquiry into the natural duration of the disease and the results of surgical treatment. A recent analysis by Eleanor MacDonald¹ of 37,863 cases of cancer is an important contribution to the subject. The facts were obtained from the records of Connecticut hospitals, and every known case of cancer admitted to or attending any of the general hospitals in the State from 1935 to 1947 was included in the analysis. The disease was diagnosed microscopically in about three-quarters of the cases. Follow-up investigations were thorough, and information about patients who left Connecticut was obtained through reciprocal arrangements with physicians, health departments, and institutions in 41 other States. MacDonald believes that the results form a practically complete record of cancer among the 1,750,000 inhabitants of Connecticut during the period reviewed. The average incidence of cancer during the seven years 1940–6 was 194 per 100,000 men and 221 per 100,000 women. The incidence continued to rise during the period, even after correction for age. The changes in the incidence and death rates appear to indicate that earlier diagnosis leads to more effective treatment and consequently more survivals. In every 100,000 living females in Connecticut 805 had a history of cancer and 220 had survived five to twelve years from the onset of the disease; corresponding figures for men were 531 and 129. One of the analyses carried out was to group the survivors by stage of disease on admission to hospital according to a broad anatomical classification. For all sites combined, 25.4% of the males and 35.5% of the females who sought treatment while the disease was localized survived for five years; when regional metastases were present on admission the percentages were 9.1 in the case of males and 19.1 in the case of females, and when remote metastases were present they were 1.4 and 3.7. The chance of surviving five years varied considerably according to the site of the disease. The lowest rate of survivorship was among the patients in the group who developed cancer in the viscera contained in the chest cavity. Even when the disease was localized on admission only 3.9% of the men and 3.5% of the women survived five years.

The age distribution of patients with microscopically proved cancer differed between the sexes. For all sites combined, the age groups 50–59 in women and 60–69 in men provided the greatest number of admissions, and the mean age of the women at the time of treatment was 55.4 and of the men 59.6. For disease in most parts of the body the average age at which men obtained treatment was generally only a year or two more than that of the women, but in the group of patients with cancer of the genital tract and external genitalia the average age at treatment was 53.6 in the case of women and 66.2 in the case of men. This study shows that between 1938 and 1946 in Connecticut delay in obtaining treatment either through personal procrastination or inadequate medical advice has been significantly reduced and that there has been a corresponding increase in the proportion of patients surviving five years or more. MacDonald suggests that, although the facts are not very encouraging, continued efforts to reduce the delay will meet with further success.

RINGWORM OF THE SCALP

Small-spore ringworm infection of the hair of children under the age of puberty presents teasing problems for the clinician, the mycologist, and the biochemist. The simplest measures will cure the infection on the smooth skin, but in the hair follicle changes occur which make treatment much more difficult unless drastic steps are taken, such as by x rays, to produce epilation of the entire hair shaft and root. These changes include altered character of fungal growth with increased spore formation, altered pH of affected skin, and biochemical changes with production of a substance causing fluorescence in ultra-violet light filtered through Wood's glass. Workers in the U.S.A. have detected infection by recording pH variations when no infection was disclosed by fluorescence under Wood's light.

The incidence of small-spore ringworm infection in school-children was so high in the early part of the century that special schools were established and catered for more children than attended the normal schools. After 1910 the incidence fell, partly as the result of x-ray therapy and partly, it would seem, because of a change of phase in the natural cycle of the disease. Between the wars the incidence was very low, but there has been considerable increase in the last 10 years. Spontaneous cure does occur in a small proportion of cases. Immunity develops after the infection is cured, but some children appear to be naturally immune and will not contract the disease in spite of intimate contact with an infected child. There is no satisfactory explanation of these facts or of spontaneous cure at puberty. New parasitocidal preparations are now available for local treatment. Emulsified bases penetrate the skin more effectively, but results are not much better than those obtained with iodine in goose grease, which was employed in the last century. The same is true of the new parasitocides—the more effective producing some inflammation in the follicle, which is undesirable.

It has been generally accepted that x rays do no more than remove the hair, so that local treatment easily clears up what then becomes an infection of the smooth skin. Some doubt about the truth of this view is expressed by Drs. F. L. Lydon, T. Stephanides, and T. M. Robb in an article appearing at page 523. They have cured over 100 cases by epilation alone—the heads being washed with soap and water, and sterile caps being replaced every second day. It may be that this is sufficient treatment to cure any infection of the smooth skin, for perfect epilation saves the dermatologist with no further worries. If, however, the dose of x rays is not quite adequate, so that epilation does not leave a shining, bald surface, or if the hair is not completely removed from infected patches, then the difficulties of treatment are, if anything, increased. This does not suggest that x rays hinder the growth of the fungus or render the "soil" less suitable. Indeed, in some cases after x-ray therapy and epilation the ringworm infection appears to become increasingly active before recovery takes place.

ENJOYING THE COUNTRY

Unlike Acts of Parliament concerned with the treatment of sickness, Acts whose purpose it is to help people to lead healthy lives seldom contain the word health in their titles. Even so, it is measures such as the National Parks and Access to the Countryside Bill, which was introduced in the House of Commons last week, that in the long run will ease the load which the National Health Service has placed on the practitioner. This Bill is designed to increase everybody's opportunities of enjoying the country. National Parks are to be created by a National Parks Commission, which will begin by considering the areas recommended

in the report of the Hobhouse Committee. The Parks will be managed by committees of local planning authorities (county and county borough councils), which will have power to provide accommodation, meals, and camping sites, in addition to their duty of preserving the natural beauty of the areas. There may be some incompatibility in these two functions, but it is tempting to look forward to the time when the committees responsible for, say, the Broads and the Lake District strive to surpass each other in imaginative (and, we hope, dignified) use of the powers they possess. The National Parks Commission is also to become the guardian of "natural beauty" in any part of England and Wales and will have power to designate areas of outstanding natural beauty, which will then be made accessible to the public and will obtain protection similar to that given to the National Parks.

Another function of the Bill is to give the public access to mountain, moor, heath, down, cliff, and beach so that they may wander without trespassing; owners of land are to be compensated for depreciation. The Ministry of Town and Country Planning is empowered to buy areas of open country and hand them over to the National Trust, or some other suitable body. County councils, with the help of district and parish councils, are to survey all foot-paths and bridle-paths, and it is hoped that at the end of three years a Domesday Book of all rights of way in the countryside will have been compiled. Where necessary new rights-of-way are to be created. The National Parks Commission is to make proposals for long-distance foot-paths—such as the Pennine Way, the Pilgrims' Way, and a path right round the coast. Finally, the Bill gives powers to the new Nature Conservancy to set up nature reserves, which are defined as land managed for the purpose of providing opportunities for studying and for preserving flora and fauna or geological or physiographical features.

FELLOWS OF THE ROYAL SOCIETY

The following were among those elected to the Fellowship of the Royal Society on March 17: Ernst Boris Chain, M.A., D.Phil., University Demonstrator in Chemical Pathology, University of Oxford; distinguished for his work on enzymes of snake-venom and bacteria, and especially for his researches on penicillin and other antibiotics. Kenneth Mather, Professor of Genetics, University of Birmingham; distinguished for his contributions to genetics and particularly for his studies of polygenic inheritance. Walter Thomas James Morgan, D.Sc., Ph.D., research worker, Lister Institute of Preventive Medicine, and Reader in Biochemistry in the University of London; distinguished for his contributions to the chemistry of immunology and blood groups. David Aylmer Scott, research member, Connaught Laboratories, University of Toronto; distinguished for his contributions to the chemistry of insulin, heparin, and carbonic anhydrase. Wilson Smith, M.D., Professor of Bacteriology, University College Hospital Medical School; distinguished for his researches on the virus of influenza and on the pathology of staphylococcal infections. Frank George Young, D.Sc., Ph.D., Professor of Biochemistry, University College, London; distinguished for his studies of the part played by the hormones of the anterior lobe of the pituitary gland in carbohydrate metabolism.

Dr. A. P. Thomson, F.R.C.P., will deliver the Lumleian Lectures before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, April 5 and 7, at 5 p.m. His subject is "Problems of Ageing and Chronic Sickness."

TRILENE AS AN ANALGESIC IN LABOUR

REPORT OF THE ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

BY

F. NEON REYNOLDS, F.R.C.S.Ed., F.R.C.O.G.

An account of the investigation into the possible use of trilene by midwives as an analgesic in labour has been issued by the Royal College of Obstetricians and Gynaecologists. The report does not seem to have received the publicity in the medical press which it demands. A standard method of administration by means of the modified Freedman's inhaler was adopted and efficacy, effect on labour, and safety for mother and child were investigated.

Results of Investigation

The results, in brief, arrived at under these headings were as follows:

Efficacy.—Adequate relief can be given to a high proportion of cases—76% to 89%—without any special skill upon the part of the administrator. The degree of analgesia provided was superior to that obtained from gas and air by Minnitt's method.

Effect on Labour.—No evidence was adduced of any adverse effect upon length of labour, forceps rate, or obstetrical interference rate. No case of diminution of uterine contractions due to trilene was recorded, but in three cases out of 1,168 unexplained delay might have been attributable to the analgesic. A small proportion—4.6%—of patients became uncooperative mainly because they became too sleepy to push in the second stage. This incidence did not appear to have any relation to the duration of the trilene analgesia.

Safety to Mothers.—In the group to which trilene alone was given there was one maternal death—a rate of 0.86 per 1,000—and that on the fourth day of the puerperium in a patient with mitral stenosis. In marked contrast the death rate was more than doubled—1.96 per 1,000—in the group to whom no analgesic or anaesthetic of any sort was given.

The conclusion, as published in the report, that "there is no evidence in this series that the standard method has any influence on the maternal mortality rate" might even be described as an understatement. The paragraphs which follow this conclusion deal with the possible effects upon maternal respiration and pulse rate. No ill effects upon respiration were noticed. Possible alterations in pulse rate are referred to, but comment here is not possible since the details published are insufficient. The information given is unconvincing because the amounts of trilene administered vary to an inexplicable and almost unbelievable degree. It is difficult to reconcile 9 ml. of trilene in twenty-eight minutes, 7 ml. in three and a quarter hours, and 7½ ml. in a little more than ten minutes.

Effects on the Foetus

Foetal Pulse Rate.—The criterion of foetal distress was taken as slowing of the foetal heart rate to a hundred or below. This occurred in 3 cases among 1,168 to whom nothing else but trilene was given. The opinions reached were not unanimous. There were 18 cases in which the point arose, but in all but the three mentioned above other factors were present, such as difficult labour or the use of other non-volatile analgesics in addition to trilene; furthermore, 11 out of this 18 occurred in the same hospital, and the observer of these cases considers that the possibility of some effect on the foetal heart rate must be borne in mind.

Asphyxia Neonatorum.—Some degree of asphyxia occurred in 3.9% of babies where trilene alone was used, but a considerably higher proportion was noticed if pethidine had been administered previously.

Stillbirth Rate.—There were 25 stillbirths, again among 1,168 patients, but in no case was the analgesia considered in any way responsible. This gives a stillbirth rate of 2.14 per 1,000. In a series of 2,040 patients to whom no analgesia or anaesthetic of any sort was given the stillbirth rate was 71.56 per 1,000. The final conclusion was that there was no evidence to show that trilene influenced the stillbirth rate in any way.

Neonatal Death Rate.—In the three groups of cases investigated the lowest neonatal death rate—5.13 per 1,000—was obtained in the series of patients to whom trilene alone was given. Where no analgesic at all was used the rate was 35.94 per 1,000, but this high incidence is explained by the inclusion of a large number of premature labours. In the group to which other analgesics as well as trilene

were given, a figure of 11.80 per 1,000 was found. The conclusions were again that trilene had no influence on the neonatal death rate.

Final Conclusions

In the final summing up the observers expressed their opinions on whether the use of trilene by unsupervised midwives trained in this method would be safe. The majority—eight in number—were of the opinion that it could be safely employed with great benefit to the mother, and stated that they would be quite happy to be responsible for a district in which the use of trilene by midwives was allowed. Two were of the opinion that further investigations were necessary and that in the hands of midwives without supervision it might be used for longer periods than was commonly the case during this investigation; and two considered it unsuitable for domiciliary midwives on account of its effect on the foetus and the production of a non-cooperative state in the mother.

In spite of this large majority and of the evidence produced, the final recommendation of the observers was that this method should not be made available to unsupervised domiciliary midwives. The reasons actually given in the report are:

(1) The limits of variation of the trilene vapour/air mixture delivered by the apparatus are far too great.

(2) Under less ideal conditions or by deliberate misuse these limits can be caused to vary still further.

(3) As a result of the above and also due to varying tolerance in different individuals cases will occur where the mother will pass beyond the stage of co-operative analgesia into a state of uncooperative stupor. This has occurred in the best of hands, and in the case of less skilled supervisors this condition might easily be taken to a state of anaesthesia.

In writing this précis every effort has been made, and I think successfully, to avoid divorcing subject-matter from context, thus conveying any false impression or biased view. Certain points deserve emphasis; the most striking, perhaps, is that the lowest mortality rates in both mothers and babies are found in that group of patients to whom trilene alone was administered. So far as maternal mortality is concerned this is a finding to which attention has been drawn before, and it is of the utmost importance that this aspect of the use of analgesics should be recognized. The low stillbirth rate is extremely interesting but cannot, of course, be attributed entirely to the use of analgesics.

The adverse part of the report relates to non-cooperation of the patient due to excessive stupor and the danger of this passing into a state of anaesthesia, together with the varying strength of the trilene vapour delivered by the apparatus. It was felt that these disadvantages might be still further increased by unsuitable home conditions or by deliberate misuse. The three cases of non-cooperation and three of alteration in foetal pulse rate constitute no greater proportion of such complications than is found in patients to whom no analgesic is given.

No one is anxious to press for an analgesic which would increase the risks to mother or infant, but the outstanding features of this report are that with the use of trilene mortality rates show an absolute decline. A certain amount of risk has to be taken in childbirth anyway, and it would appear reasonable to suppose that the risks of using trilene, such as they are, would at least be offset by the consequent reduced mortalities. A risk is taken every time an anaesthetic is administered; fatalities have been reported even under gas for removal of teeth, but no one would demand minor operations being carried out without its use. Is it reasonable to take for granted that midwives would deliberately misuse the apparatus by placing the bottle in hot water or would adopt other illicit means to increase the dosage? My experience of them does not support such an idea for a moment. If the practice is known to exist, surely it can be remedied in some way other than at the cost of human suffering?

One is forced to the conclusion that the investigation upon which the report from the Royal College of Obstetricians and Gynaecologists is based produces all the evidence in favour of a trial of this method being made. I must repeat that eight out of twelve observers were of the opinion that it could be safely so used; the majority of them (number not given) stated that they would be quite happy to be responsible for a district in which trilene was available to domiciliary midwives. We have no alternative analgesic the practical application of which is so

widely possible. I would ask, therefore, that districts be chosen in which a clinical trial can be carried out upon a much wider scale than the scope of the recent investigations allowed. I believe the results would more than justify the undertaking.

We must ask ourselves whether the doubts of the few or the slight risks they envisage should prevail and thus deprive thousands of women of the relief so greatly needed. Let those who have expressed their readiness to shoulder the responsibility be allowed to take action without further delay to rectify a state of affairs which is causing national anxiety.

STRATEGY OF HEALTH EDUCATION

TELLING THE PUBLIC

The subject of a symposium arranged by the Public Health Department of the Middlesex County Council on March 14 was "The Principles and Technique of Informing the Public." The all-day meeting was attended by the public health and other staff of the council, and medical officers and health visitors from neighbouring authorities. The words of Lord Derby, who was Prime Minister in 1866, stood at the head of the programme: "Health instruction is even more essential than health legislation, for the best laws are waste paper if they are not appreciated and understood."

Dr. W. HARTSTON, deputy county medical officer of health, who presided, said that the purpose of the symposium was to give the Middlesex authorities some guidance on health propaganda. The people most in need of health education were not people of the highest intelligence nor with any wide range of ideas; they belonged to that 30% who were in grades 4 and 5 of the five intelligence groups in the Army intake during the later years of the war. Therefore the educational appeal must not be pitched too high.

Health education, Dr. Hartston continued, was bound to be a somewhat disappointing business. "Many are taught, but few learn." But if it could be imparted satisfactorily and acceptably it would rid us of most of our avoidable afflictions. He pointed to the success obtained with diphtheria immunization. That could be said to be the result of teaching and propaganda. He mentioned Harrow in his own county, with a population of over 200,000, which in the years 1946-8 had no deaths at all from diphtheria, and in 1948 no cases; yet he supposed Harrow had its share of the above-mentioned 30%. Dr. Hartston suggested that time might be bought on Radio Luxembourg to "call all lumbagos"—or any other class. This suggestion was opposed by Dr. CHARLES HILL, the next speaker, on the ground that people would say, "What is Middlesex County Council up to? Can't we keep our own backsches?"

Personal Contact

Dr. Hill began by saying that in all forms of health education the fact must be reckoned with that the vast majority of people in this country, while they had a lively interest in ill-health, had relatively little interest in the maintenance of good health. The purpose of health education was to modify that attitude. Too little was known about the prevention of disease. The public was apt to assume that there was a mass of knowledge which, but for the reluctance of those who possessed it, would be available for general assimilation. The sad and depressing truth was that there was really very little knowledge. It was perhaps no longer true that practitioners were "brought up on the rare to go out and treat the trivial," but pathology dominated the curriculum, and physiology had a long way to go before its rightful position was achieved.

Dr. Hill doubted whether health education for the over-forties was worth while. Habits of life and conduct, of eating and drinking, were then firmly laid down, so that it was beyond the power of the most enthusiastic health educator to jerk them out of their routine path. As for the means of health education, he thought that exhibitions, like lectures, were largely a waste of time, attended for the most part by the converted. As for posters and leaflets, there had been an immense improvement in recent years. Especially commendable were posters which had a touch of humour, like those

of Fougasse for the Central Council for Health Education. But the most effective medium was the spoken word—spoken by the doctor or health visitor. He hoped that eventually the burden of work on the doctor would be eased so as to give him more opportunity for these personal contacts.

For broadcasting on health subjects, or indeed on anything else, Dr. Hill laid down some simple rules: (1) Take advantage of the fact that people are interested in ill-health, and use ill-health as an opening for passing on to more positive instruction. (2) Don't despise small and unambitious jests. Don't be afraid of saying something which might not be wholly approved by an audience of medical practitioners. (3) Never mind Sir Ernest Gowers: talk English as you ordinarily talk it.

The Written Word

Mr. MACDONALD HASTINGS, editor of the *Strand Magazine*, discussed the value of the written word, remarking that what sounded well very seldom read well, and vice versa. He looked with more toleration than some on the popular press. He saw in its sensational headlines and comic strips not the signs of declining popular intelligence but the emergence into relative literacy of a population which previously had read next to nothing at all. He even excused the inaccuracy with which medical matters were often handled in the lay press. Four-fifths of it was the profession's own fault. Not once in a thousand times did a newspaper set out to print something that was false. The errors arose from the speed with which newspapers were published, the enthusiasm of individual reporters, and the absence of satisfactory liaison between the medical profession and the Press so that there were no rapid means of obtaining an authoritative opinion.

In the general discussion, in which several health visitors took part, it was suggested that the county council should have a whole-time health education officer, not necessarily a medical man. Suggestions were made for sample surveys, also for area group studies, the group being formed of medical officers, nurses, health visitors, and school teachers. The final word was with a dental officer, who pleaded that, while there might well be education directed to the prevention of caries, there should be no propaganda for more dentistry—at present.

MENTAL HOSPITAL RECORDS

A conference of the Psychological Medicine Group of the Association was held at B.M.A. House on March 7, with Dr. W. G. Masefield in the chair, principally to discuss the question of statistical returns from mental hospitals. Dr. C. P. Blacker, who has played a considerable part in devising the new system of records, said that he must not be regarded as responsible for all the final features of the system. He would have liked to see some of the questions differently framed, and he regretted the use of a hospital index card as a substitute for a case-sheet front page.

Turning to the hospital index cards now in use, he discussed the genetic and demographic questions numbered 20 to 29. The first question, concerning twins, scarcely required comment; the value of twins for genetic research was universally recognized. Another question asked whether the parents were related by blood. It ought to have been specified in the handbook of instructions that first-cousin marriages were here intended. The question was capable of bringing to light new forms of mental defect, or perhaps of disorder, in which recessive genes played a part. Question 22 asked whether the patient was related by blood to his first spouse; the question was limited because to have brought in second or later spouses would have introduced too many complications. But the question had an important bearing on the amount of consanguinity, which varied in different localities. With regard to the next question, which asked whether the spouse had been dealt with under the Acts, a wider net might have been cast by asking whether the spouse had ever been treated by a psychiatrist: but questions of interpretation of "psychiatrist" would have arisen, and there was much to be said for confining questions to simple factual alternatives.

Another question was on the age of the mother at the birth of the patient; the significance of this in relation to mongolism was well known. The answers to the questions relating to siblings would bear on the fertility of the parents of the mental hospital population, and the question on the number of the patient's children born alive would give information, though incomplete, about the fertility of that population.

This year the analysis of mental health records would now be made with Hollerith machinery instead of by the laborious pen-and-ink methods hitherto followed. Nevertheless, the labours that the new arrangements would impose on Somerset House would be immense. In time, he hoped, the bulk of the pressure would be removed if properly equipped statistical departments, perhaps linked with the departments of social medicine in the universities, were established in every region. Such regional departments could provide a statistical service to every hospital. Professor Ryle had suggested that these regional departments should be assigned dual functions—namely, a statutory function to provide the central office with whatever statistical material it might require, and an independent local function of helping the regional hospitals and other bodies and the university in their research projects.

The present format of index cards should not be regarded as immutable; indeed, he had the authority of Mr. Barter, chairman of the Board of Control, for saying that they would not be. Dr. Blacker suggested a plan whereby the Board could pursue a systematic and yet elastic programme of research by issuing to hospitals and institutions new front pages of case-sheets at intervals. It would be most advantageous if interested departments—such as social medicine and genetics—could be notified of cases interesting to them, and he was convinced that the dangers of such a system were much exaggerated. The public was accustomed to the notification of dangerous or contagious diseases; it would be but a step to accustoming it to the notification of interesting diseases or circumstances from which useful information could be gained.

Social Influences

Professor T. Ferguson Rodger addressed the conference on the value of diagnosis in clinical records in mental hospitals. At the present time, when vast decisions were frequently taken which affected the mode of life of everyone in the nation, the psychiatrist, alive to his social responsibility, was being forced into an active role. How far was the psychiatrist equipped to give advice on planning? Possibly in this country, thanks to the work of E. O. Lewis, more was known than in any other about the incidence of mental defect, but how much was known of the social conditions which gave rise to neuroses? He would like to know—he could not discover—how much loss of production, psychopathy, delinquency, how many prison cells and mental hospital beds, should be placed to the account of the bad housing conditions of the Gorbals of his own Glasgow. The present position of psychiatrists was like that of a physician concerned with individual symptomatology but not realizing the importance of sanitation.

When one thought along these lines the new index card seemed a very modest affair. In an era of planning it was probably more important to know about these things—social influences—than about genetics. For the first time entire new towns were being planned before they were built. Physical hygiene had had its say in planning them, and they ought to be in a position to provide accurate information about the requirements of mental hygiene. A town could now be planned for a low infant mortality rate; it should be possible to plan a town for a low delinquency rate. The index card was on the right lines for setting going a scheme of social research. Mental hospitals would always be the chief training centres for the psychiatrist, and careful case-taking was a necessary part of his training. They could not hope to cover all relevant factors completely, and if very detailed records were insisted on case-taking might become an end in itself; but a good clinical record should reveal the dynamics of the case and suggest the problems which were to be tackled either by psychotherapy or by social adjustment.

Professor Rodger referred to the handicap of the large variety of diagnostic classifications which had been used in the past. A great deal could still be done in following up

the after-care of patients who, while they might recover from the attack and leave hospital, presented a very different picture when next admitted. The correlation of diagnosis and prognosis might help to narrow down the very large margin of error which occurred when labels which had prognostic significance were attached. The fact that the response of the manic-depressive patient to electroplexy was so different from that of the schizophrenic was only one of the unmistakable indications that diagnosis was a highly significant procedure. "New diagnostic procedures are being introduced," said Professor Rodger in conclusion, "and research on clinical assessment will no doubt continue with the aim of achieving a better classification. In the meantime, in the evaluation of treatment, in genetic studies, in research on pathology and psychopathology, our present classification is capable, if we use it properly, of serving us well for many years to come."

Dr. Doris Odum complained of the vagueness and wooliness of the classifications at the present time. Nearly all diagnosis was descriptive, so that they were very likely, if a case took a certain course, to assume that the diagnosis had been wrong—in other words, to judge diagnosis by the end-result. Dr. Rees Thomas said that what they had tried to do in the index card was to be factual. A great many things had been left out, but one factor of great importance was left in—namely, the physical condition. The system allowed for a change of diagnosis. It had seemed a little unfair on any doctor to allow him to take an early case, make his diagnosis within a maximum of three months, and hold him down to that diagnosis for all time.

Dr. Masfield, in closing the discussion, said that the Board of Control was to be congratulated on having produced these index cards. There was nothing to stop anyone adding information to them.

MALARIA AS A WORLD PROBLEM

UNIVERSITY OF LONDON LECTURE

Professor B. G. MAEGRAITH, of the Liverpool School of Tropical Medicine, delivered a University of London lecture on Feb. 24 at Westminster Hospital Medical School, his subject being "Malaria as a World Problem."

Not enough attention, said Professor Maegraith, was given to malaria in the average medical curriculum. Yet malaria was the most widespread of human diseases, not even excepting the common cold. Its mortality was comparable with that of the influenza pandemic of 1918-19, and, while malaria was a disease which killed, it was even more a disease which produced a high morbidity. It was primarily a disease of rural areas, and it must be regarded as a great cause of world food shortages, slowing down agricultural production over vast areas. In war it interfered with strategy. In the 1914-18 war it nearly paralysed operations on both sides in the Balkans, and in the last war it was not until some control over malaria was established that the fighting in the south-west Pacific could proceed.

The lecturer went on to discuss the natural history of malaria and the methods by which it was spread. Malaria, he said, could be recognized from the earliest human records; it was common in Greece and Rome. The ancient doctors were able to separate fevers into two classes, continuous and intermittent, and the intermittent fevers must have been malaria. The organism was not seen and described until the early nineteenth century. Laveran was the first to prove in 1880 that it was present in the blood and was in fact a protoplasmic parasite. Manson argued in an article in the *British Medical Journal* in 1894 that the malaria parasite could be picked up from human blood by mosquitoes. He propounded the theory that the mosquito carried malaria. Pfeiffer, some years earlier, had also suggested that the mosquito might carry the parasite, and had mentioned this to Koch. Ross, studying avian malaria, traced the parasite from the blood of the bird to the mosquito, and from the mosquito to another bird. The final proof of the transmission of human malaria was given by Manson at the London School of Tropical Medicine when he demonstrated the complete cycle.

Methods of Control

It was on this basis that attempts to control malaria rested. If only the parasite could be destroyed in the human blood the

infection could be got rid of altogether. To this field had been brought the armamentarium of chemotherapy. Theoretically it might be possible to provide some chemical barrier beyond which the parasite could not pass, but there was at the moment no chemical substance which would destroy the parasite when it was injected. The parasite, however, underwent a phase of its development in the tissues before it entered the blood stream, and there were certain chemical substances which were of use here, the outstanding ones being mepacrine and paludrine. How effective these drugs could be was shown in the last war when, up to 1942, the incidence of malaria in the south-west Pacific was such that warfare was almost impossible; then mepacrine was introduced and used almost under duress, and the incidence of malaria fell markedly. But when it came to dealing with the control of malaria in large communities it must be admitted that chemotherapeutic means were of no real value over a long period.

The mosquito could be prevented from biting man by screening. Screening was valuable under certain special conditions, but it was a costly business and over a wide range of humanity almost impossible. Repellants had been used—substances which made the body unpleasant to the mosquito—but there was no substance which would last long enough to give real protection. One was driven to deal with the mosquito itself. It could be killed by the introduction of natural enemies, such as fish, by the drainage or control of swamps, or by the deliberate distribution of insecticide. Professor Maegraith discussed the different methods and their application in various parts of the world, and described the use of insecticides, principally D.D.T. and gammexane. D.D.T., he said, had been developed to a point where its residual activity was such that spraying need be done only once every two or three months. It had no very outstanding "knock-out" effect, but its residual effect was very important. The mosquito took a week or more to become infective after taking blood from a human subject. When exposed to these substances it could not live long enough to become infective, and so the chain might be broken. This method of residual spraying had made all the difference in rural communities. It had made the control of malaria in big territories a feasible proposition.

FAMILY PLANNING CLINICS OPPORTUNITIES AND LIMITATIONS

A medical conference was organized in London on March 12 by the Family Planning Association. It was attended by between sixty and seventy medical officers of F.P.A. clinics, of which there are now 78, run by 64 branches. Dr. HELENA WRIGHT and Dr. ANNIS GILLIE presided over the two sessions, the main subjects being the help to be afforded by the clinics in cases of marital difficulty and in the treatment of minor gynaecological conditions and subfertility.

Adjustment of Marital Relations

The subject of marital difficulty was opened by Dr. STELLA CHURCHILL. She remarked on the number of cases in which mutual satisfaction in marriage was not achieved; such failure, of course, was not to be laid wholly at the door of the wife; perhaps it derived much more often from the husband. But she addressed herself to one particular psychological cause in women—namely, narcissism, the self-regarding state. The narcissistic woman, she said, was in love with the idea of being in love, and too many got no further in marriage than that. The pity was that many of these narcissistic women were superficially attractive, but they had very little idea of the element of giving in the marriage relationship.

Dr. NOEL HARRIS referred to the distinction between cases which could be helped at the clinics and those which should be referred for specialist treatment. It was always a matter for consideration by the clinic officer whether underlying what appeared to be a superficial and temporary condition was a neurosis. A large number of what were termed anxiety states might not be linked up in any way with a neurosis but might simply be attached to a particular problem. Each person had

a constitutional pattern, and the normal personality was a blend of many types which in their abnormal manifestations were schizoid (reserved and solitary), obsessional (methodical, precise, exact), and so forth. When a marked personality type was encountered it was necessary to be on one's guard; slight obsessional tendencies might indicate a neuropathy which required more expert handling and more time than a clinic could afford.

Dr. HARRIS went on to discuss conditions of impotence in the male. These included failure of erection, premature ejaculation, and lack of sexual desire. Premature ejaculation was very frequently associated with an anxiety state, and if the anxiety was relieved and adequate instruction given the condition would pass away very rapidly. Failure of erection was much more difficult to deal with. It might be a local condition or linked up with some constitutional disturbance, though definite proof of the latter might be lacking. Very little could be done about it. The value of injections of progesterone, he thought, had not been established. Failure of erection might be closely connected with lack of sexual desire, which was much more likely to need intensive and prolonged treatment. Very probably the underlying condition was depressive. Frigidity was often associated with sexual weakness as well as with lack of knowledge of sexual technique. Finally, he touched on perversion, often misunderstood and badly dealt with, and homosexuality, which he did not think in its extreme form could be cured by any psychological treatment. It was sometimes forgotten that extreme homosexuality was at one end of a scale and normal heterosexuality at the other, and in between there were any number of intermediate grades, in some of which help could be given.

Minor Gynaecological Conditions

Dr. JOSEPHINE BARNES began by saying that gynaecology could scarcely be divided into minor and major, and that minor gynaecology could hardly be said to exist. Nevertheless, there were a number of conditions in which the clinic could afford help to the patient. One very common condition among married women was the early case of prolapse. Personally she thought that ring treatment should be resorted to very seldom; quite a number of ring ulcers and occasionally carcinoma were seen. Most cases of prolapse were better operated on. In early prolapse a measure of extreme value was physiotherapy. In cases of retroversion it was necessary to be careful what one said to the patient. So often patients came up saying that they had been told that their womb was "twisted." She preferred to tell them that the womb was tending to fall back. Very few operations for retroversion were done, but in some cases operation was worth while.

In cases of leucorrhoea the treatment should be directed to the inflammations which gave rise to it. For cervicitis by far the most satisfactory method was cauterization with the electrocautery. Various degrees of vaginitis caused leucorrhoea. The vagina had on the whole a successful defence mechanism, but once this was upset there might follow infection by various organisms. Dysmenorrhoea accounted for about half the outpatients seen nowadays; in the spasmodic type it was worth giving stilboestrol a good trial; the congestive type was much more difficult to treat. Finally Dr. Barnes touched on the early diagnosis of cancer and again stressed the diagnostic value of the clinic consultation.

Treatment of Subfertility

Mr. LINTON SNAITH considered that the task of the clinic doctor should be restricted to making the initial examination and giving reassurance and general advice. F.P.A. clinics should not be turned into minor hospital departments. There were two chief types of cases for which such clinics were ideal: cases in which there were difficulties in marriage arising from sexual maladjustment, and genuine cases of subfertility after two years or more of marriage. The clinic could in the latter cases initiate investigations and sometimes, in full co-operation with the hospital staff, deal competently with the cause. After marriage many cases came forward while as yet there was no real evidence of subfertility, and he suggested that clinics, while admitting the value of investigation, should not rush into it too

soon. The competent clinician could make a pretty good estimate of subfertility, and in many cases reassurance was all that was wanted. As for the genuinely subfertile group, those who had been married for two or three years without conception, many of these cases must be dealt with at the hospital and not at the clinic, though if investigation showed the problem to be one of marital maladjustment the help given by the clinic might be sufficient to put it right. It was surprising in how many cases the sex relationship was unsatisfactory after years of marriage.

The chief cause of subfertility was constitutional—meaning both the physical and the psychological constitution—and in the majority of cases this could not be modified, though much could be done to keep the morale of the couple high. Some of the functional causes of subfertility were obscure. He was a little critical of the various methods adopted for the treatment of tubal spasm, and was not convinced that antispasmodics had any effect. Of the organic causes tuberculosis was one of the most important.

MEDICAL FILMS

Excision of Intervertebral Disks

Mr. J. E. A. O'Connell is to be congratulated on his film "Excision of Intervertebral Disks," made in the Department of Neurosurgery at St. Bartholomew's Hospital.

The first part of the film shows the physical signs of a "typical" disk protrusion. This is followed by shots of the operation illustrating the main points of Mr. O'Connell's technique. The earlier part of the operation shows up very well indeed, but the pictures of the exposure of the nerve root and the removal of the disk are on the small side. This part of the operation must be one of the most difficult to photograph satisfactorily owing to the very small area that has to be shown at the bottom of a very deep wound. In Mr. O'Connell's film it would be difficult for a person not well acquainted with the detailed anatomy of this part to appreciate that the disk in the picture was actually protruding. Moreover, the non-expert might have some difficulty in recognizing the nerve root. To convince a disbeliever so far as this lesion is concerned one must be able to show the disk "sticking out" and not merely as a shiny flat surface.

The final part of the film deals with the after-treatment and shows the type of exercises the patients perform. The film is in colour throughout and is of a uniformly high standard. It should be of great value and interest to those already acquainted with the operation. It would have a much wider appeal, however, if some close-up shots of the region of the nerve root and intervertebral disks could be incorporated.

NURSES AND THE N.H.S. NATIONAL CONFERENCE

The sixth of a series of national conferences on nursing problems, arranged by the Royal College of Nursing, was held in London from March 3 to 5, when the general subject was "The Machine and the Nurse," meaning by "the machine" the new hospital arrangements under the National Health Service. The conference was attended mainly by matrons and principal nursing officers. The practice was followed of having discussions in groups and of bringing forward the group conclusions at plenary sessions.

Dr. John Kershaw, divisional medical officer for North-East Essex, pointed out that the "machine" was a new one. Many of the difficulties were administrative, and, like the problems of civil defence in war, would settle themselves in time. The administrators were themselves experimenting and changing their ideas. New people were being brought into hospital management. Some regional boards had brought on to hospital management committees people who had never had anything to do with hospitals before, but whom they thought could be trained to be sound hospital administrators.

There were many expressions of assent when Dr. Kershaw said that he gathered that nurses did not feel they were getting

a fair voice in hospital management at the present time. In the old days the matron had considerable power, for committees were composed of lay people among whom her special knowledge of administration counted for much. The nursing side should have fair representation, and matrons should be given access to committees where their special administrative knowledge would be of value. Dr. Kershaw said that what was wanted was a smooth-running administrative machine at national, regional, and hospital levels, and to get this it was necessary to compromise. The administrators should be prepared to make a little concession to administrative untidiness where human needs conflicted with "streamlining."

The principal theme at the concluding session was the place of the matron or nursing representative on hospital management committees. Some of the matrons present claimed that, even if technically not members of such committees, they should have a right to be present when matters affecting nursing were discussed. Others said that it was of even greater importance to have the right to attend subcommittees; the main committee often did no more than "rubber stamp" subcommittee decisions. The question of presenting nursing opinion to the regional boards was also mentioned. It was stated that one regional board had invited more than fifty matrons in its area to a meeting at which they had given the board and its chairman their views on nursing matters.

Regional meetings of principal nursing officers were strongly advocated. Another point on which there was general agreement concerned the need for cultivating social life in hospitals. The day of the ridiculous shut-in sitting-room where nurses were allowed to receive visitors only at certain times had ended or must end. It was suggested that the lack of social life in hospital nursing was one of the main factors militating against recruitment.

Preparations and Appliances

A PORTABLE RESUSCITATOR

Dr. B. G. B. LUCAS, research assistant in anaesthesia, University College Hospital, writes: Now that the respiratory depressants, such as the barbiturates and curare, are in common use in anaesthesia and in electric convulsion therapy, some form of resuscitation apparatus becomes almost a necessity. Kreiselman (*Anesthesiology*, 1943, 4, 608) described a simple resuscitator consisting of a bellows bag and face-mask. This has been modified so as to use oxygen, and has been constructed from standard parts so far as is possible.

The apparatus consists of a Connell bellows bag mounted on a McKesson pattern face-mask. On the base plate of the bag is a Heidbrink expiratory valve which can be loaded, and an inlet pipe through which oxygen is fed from a 30-gallon (136-litre) cylinder via a combined demand regulator and reducing valve. The regulator is set at atmospheric pressure so that oxygen flows automatically when the bag is expanded or if the patient breathes of his own accord. The whole apparatus is carried in a fibre case 19 by 13 by 8 in. (47.5 by 32.5 by 20 cm.) and weighs 25 lb. (11.34 kg.) complete. No spare cylinder is carried, but an oxygen-content gauge is mounted on the side of the reducing valve (see accompanying photograph). This apparatus was made for me by Medical and Industrial Equipment, Ltd., 12, New Cavendish Street, W.1.

Reports of Societies

TRAUMATIC CHANGES IN THE BRAIN AFTER DELIVERY

At a meeting of the Section of Neurology of the Royal Society of Medicine on March 3, with Dr. WILLIAM JOHNSON, the president, in the chair, a lecture was given by Professor B. BROUWER, of Amsterdam, on "Traumatic Changes in the Brain after Spontaneous Delivery at Full-term." The president introduced Professor Brouwer as a neurologist whose fame was world-wide and whose Neurological Institute many of them had visited with great profit.

Professor BROUWER said that he proposed to present certain material from the Neurological Institute at Amsterdam in the preparation of which he had worked in collaboration with Dr. Cornelia de Lange, professor of paediatrics at the university. They were all aware of the clinical syndromes which might arise after birth—for example, muscular palsy, spinal paralysis, mental disorders, and idiocy. Haemorrhages into the pia and arachnoid and in the central nervous system might occur after almost every birth and disappear spontaneously. The number of cases in which blood was found on lumbar puncture was high, and not infrequently haemorrhages were seen in the retina. Destructive processes in the central nervous system might be observed not only in the premature infant but also in the infant born at full-term and without instrumental aid. The examination of such cases of birth injury had shown that not only were haemorrhages frequent in various parts of the central nervous system but that other processes might also be present. Destruction was seen, for example, in the striate bodies, and it was rare for the effects of birth injury to be confined to the pia.

Over the last two years his Institute had received the brains of six children, all delivered spontaneously at full-term, in which there were found signs of intracranial birth injuries. In four cases the brains had been studied microscopically; in the other two the examination was still proceeding.

Illustrative Cases

The remainder of Professor Brouwer's lecture consisted of a detailed account of each of these cases, illustrated by lantern slides of brain sections. The first of the four cases was a girl, a vertex presentation, whose birth weight was 3,520 g. For some days after birth she had convulsions, for which she was treated in hospital. In a short time the condition improved and the child was sent home. At five months she was readmitted suffering from frequent epileptic fits. Ophthalmological examination revealed no retinal lesion, and there were no signs of meningitis. There was marked microcephaly. Examination post mortem showed a central haematoma in the parietal region. Sections of the medulla might be regarded as normal, and the pyramidal tracts were well formed. Microgyria was very evident. The architecture of the occipital lobe was altered, and among other brain changes he called particular attention to a peculiar "cactus" formation in the neuroglia. Conglomerations of fat cells were seen in many parts of the brain. Degeneration was seen only in the pallium; the deeper structures of the brain were largely unaffected. His conclusion was that the changes were not caused by congenital malformation but were the result of brain trauma at birth. The question arose whether the microcephaly might also be regarded as the result of birth trauma. Systematic examination of the brain pointed strongly to a traumatic origin for the microcephaly. It seemed likely that this was caused by compression at birth.

In the second case death occurred on the thirteenth day. The cranium seemed small, and only a small quantity of fluid could be removed by lumbar puncture. A clinical diagnosis of meningitis had been made. On post-mortem examination blood-clot was found on the posterior half of the right ventricle, and small conglomerations of glial cells were seen in the surrounding tissues.

The third child was taken to hospital with fever and diarrhoea, and the consulting neurologist suggested the possibility of a lesion of the brain stem. After some improvement the child was discharged, but was readmitted and died at 13 months. On

examination great destruction was found in the corpus cerebri, with the formation of cavities. Here again Professor Brouwer concluded that subdural haemorrhage following birth injury had led to under-development of the brain with great destruction of the cortex, but the deeper parts of the central nervous system had been left intact.

The fourth case was the second child of healthy parents, and had developed epileptic fits at the age of 7½ months, but no objective neurological symptoms were found. The child died at the age of 2 years and 4 months, and again on examination of the brain it was found that a great deal of the cortex was destroyed. It was true that in this case the epileptic fits had not occurred until several months after birth, but it was well known that such fits might take place after a "silent" period.

PHARMACOLOGICAL EXPLORATIONS OF PERSONALITY

Professor JEAN DELAY, who holds the chair of psychiatry in the Faculty of Medicine of Paris, gave an address in the Section of Psychiatry, Royal Society of Medicine, on March 8. The chair was taken by Dr. J. R. REES. Professor Delay, who was elected an honorary member of the Section, was visiting this country in connexion with the International Congress of Psychiatry to be held in Paris in 1950, of which he is chairman.

Professor Delay spoke first of the history of the use of drugs to recall forgotten memories and to explore latent personality. The modern use of drugs in the study of psychopathology dated from 1845, when Moreau de Tours concluded that dreams experienced under the influence of hashish were identical with the hallucinations of psychotic patients. Other drugs came into vogue later, and now interest was centred on the sodium barbiturates and methedrine. In speaking of hashish, Professor Delay related the following case history.

A lad of 18 had quarrelled with his mother and stepfather and left home. One night he visited a black-market restaurant and purchased some cigarettes. While smoking the cigarettes he had an acute hallucination. He made straightway for his former home, where he found his stepfather in bed, strangled him, and returned to his lodgings. Waking late the next morning, he was overwhelmed by his recollections of what he had done, and gave himself up to the police. The police, on visiting the house, found the stepfather having his lunch. The son had not visited the house at all, and nothing had happened. The cigarettes had contained hashish.

The sodium barbiturates had been increasingly used for narco-analysis, particularly during the war, not only in the treatment of acute combat neuroses but also for the diagnosis of malingering. Many techniques were employed, but the common basic approach was the exploration of the unconscious. A distinction must be made between the techniques in which the doctor was passive, allowing the drug to elicit the unconscious material alone, and those in which he played an active role, questioning, suggesting, and interpreting to the patient.

Methedrine, whose psychotonic action was first discovered in 1938, produced on intravenous injection (30 mg.) a state best described as "methedrine shock," with raised blood pressure as well as psychological effects. It was twice as powerful as benzedrine. The sodium barbiturates were "psycholeptic," producing a lowering of intra-psychic tensions, depressing the psychological tone; methedrine was "psychogogic," increasing intra-psychic tension and acting as a stimulant. Professor Delay was particularly interested in the psychosomatic effects of narco-analysis—that is to say, the exploration of the somatic behaviour, the emotional language of the *soma* as evidenced by tics, coughs, praecordial pain, and other manifestations.

Manic and depressive states could be relieved for short periods by sodium amytal.

A stuporous woman aged 42 was brought to hospital following an attempt at suicide. She was completely mute. When given methedrine she became agitated, cried, and with dramatic gestures declared that she had murdered her child. After a few hours the stuporous condition returned. Three days later she was given sodium amytal, and there was complete disappearance of all anxiety. Her mood was one of happiness and warmth. She was now able to give an account of her melancholic state, and she knew that she had not killed her child. By the use of both drugs the underlying pattern of ideas was discovered.

Sodium amytal, by decreasing the anxiety, enabled the patient to externalize the problem, while methedrine, by increasing the anxiety, forced its production. In schizophrenia, Professor Delay said, the presence or absence of catatonic features was important. These, when present, diminished in intensity with sodium amytal, but became more marked with methedrine. When not apparent, methedrine might bring them to light, whereas sodium amytal had no such effect, but facilitated contact with the patient. Psychological tests showed likewise the different actions of these two drugs.

Neurotic States

In the acute neuroses methedrine was of value diagnostically, but even more so therapeutically, its action being rapid and effective where emotional abreaction was the basis of cure. It appeared to be particularly valuable in exploring thoughts already present in consciousness but not freely expressed, whereas sodium amytal was more effective in revealing unconscious forces and in relieving amnesic states. Given together, the results were striking. In other words, methedrine was more useful in those cases in which the patient was unwilling to talk but knew unconsciously what to talk about, and sodium amytal was useful in cases where the patient was willing to talk but did not know what to talk about.

In chronic neurotic states the therapeutic results were not so good. The whole personality was much more deeply involved. Repeated sessions, with or without injections of these drugs, were necessary, since the problem was one of emotional re-education. Methedrine could be used only rarely, but through its "psychogenic" action it might be effective in externalizing conflicts where sodium amytal had failed. This was particularly true of psychasthenic states. There was, however, a risk of habit formation and addiction. Drug addiction could also be treated by combining methedrine and narco-analysis, methedrine being particularly useful in relieving the depressive symptoms resulting from the withdrawal of the addiction drug.

NUTRITION AND FERTILITY

NUTRITION SOCIETY CONFERENCE

A conference on "Nutrition and Fertility" was held on March 5 at the London School of Hygiene and Tropical Medicine, with Professor W. C. W. NIXON presiding.

Dr. J. HAMMOND, F.R.S., discussed the physiology of reproduction in relation to nutrition, and gave many examples of the interaction of endocrine systems, seasonal influences, and nutritional factors in farm animals. The predominant part played by the anterior pituitary in promoting growth and sexual development was emphasized; in cattle deficiency of vitamin A may affect growth indirectly by causing pituitary lesions. In animals with restricted breeding seasons the desire and ability to mate might be delayed either by poor general nutrition or by deficiency of some particular nutrient, but a rich diet, unlike exposure to light, could not bring on the breeding season before its usual time. Experiments on sheep indicated that adequate nutrition during the latter months of pregnancy was essential for the production of large, strong offspring; under-nutrition during the early stages of pregnancy had no serious ill effects on the progeny.

Dr. A. WALTON commented on the wide variations in the amounts of semen produced by different animals, but considered that even in boars producing 750 ml. of fluid per week the loss of nutrients involved was quantitatively trifling, and did not include any unusual factors which could not readily be derived from a normal diet. Mr. J. EDWARDS said that there was little evidence to suggest that the diets given to bulls used in the artificial insemination service in this country were a limiting factor in determining their fertilizing power.

Dr. S. J. FOLLEY spoke on the influence of nutrition on female fertility, with particular reference to endocrine changes. Malnutrition might prevent the normal functioning of oestrus in rats by suppressing the development of the ovaries, which might, however, be stimulated into activity without improving nutrition by the administration of the appropriate hormones. Deficiency of vitamin E, commonly known as the "anti-sterility vitamin" on account of its action in preventing foetal death and resorption in rats, had been reported to cause injury

to the pituitary gland. Malnutrition might also affect the metabolism of the sex hormones by preventing their inactivation. Thus in deficiency of vitamin B₁₂, or in cirrhosis of nutritional origin, the power of the liver to inactivate oestrogens was reduced. In herbivora, interference with fertility sometimes occurred through the ingestion of plants, such as subterranean clover, which contained oestrogenic factors. In this country the adverse effect exerted by spring pasture on the composition of cows' milk might possibly be due to the inclusion of plants with oestrogenic activity.

Malnutrition in Pregnancy

Professor A. St. G. HUGGETT said that experience in communities suffering severe dietary deprivations had shown that both the birth rate and the weight of the babies at birth were greatly reduced. In the siege of Leningrad, when the main item of the diet was 400 g. of bread daily, 50% of the babies weighed less than 2½ kg. at birth. In non-pregnant women severe malnutrition usually caused amenorrhoea. Deficiency of vitamin E in experimental rats brought about the termination of pregnancy, with death and resorption of the foetuses. Vitamin A deficiency also interfered with reproduction. Lack of this vitamin in pigs during the early stages of pregnancy sometimes caused congenital eye abnormalities, which recalled the observation that infection of the human mother with rubella during early pregnancy was often responsible for cataract in the child. Warkany had found that when rats were exposed to deficiency of riboflavin during the early stages of pregnancy their young, among other deformities, had cleft palates and defective ossification. Under-nutrition in the pregnant woman had one good effect in partial compensation for the reduced birth weight of the child; most authorities agreed that the incidence of toxæmia was greatly reduced.

Dr. G. J. M. SWYER pointed out that whereas in many Eastern countries chronic malnutrition was associated with fertility rates so high as to lead to serious over-population, in the West superior levels of nutrition were usually associated with much lower rates of reproduction. Social and economic restrictions might therefore be more important than limited food supplies in checking human reproduction. Experience in Russia, Holland, and Asia during the war, however, indicated clearly that grossly inadequate diets led to widespread amenorrhoea and loss of libido, with a great reduction in the conception rates. In communities where good nutrition was subsequently restored these defects were speedily corrected, while the conception rate tended to rise much above its normal level. The scanty menses and poor powers of reproduction sometimes found in unduly fat women, however, indicated that obesity, no less than semi-starvation, might hinder fecundity. Possibly the excessive fat deposits interfered with the action of oestrogens by removing them from the blood stream. Also obese women often had infections of the cervical canal with *B. coli*; it had been claimed that this condition might be cured, with substantial reduction in body weight, by the adoption of a diet in which sucrose was replaced by lactose. The failure to inactivate oestrogens in vitamin B deficiency might be of clinical importance in causing excessive uterine bleeding, cystic mastitis, and premenstrual tension. Claims that vitamin E was effective in combating male infertility had been contradicted by several workers, although it was possible that the doses given were inadequate. In regard to female fertility Bacharach had claimed that the combined results of early trials provided unequivocal statistical evidence of the value of the vitamin in the treatment of habitual abortion; no valid criticism of this conclusion had yet been advanced.

Mr. A. L. BACHARACH mentioned that the substitution of white flour for "national" flour in the diet of a rat-breeding colony caused anaemia and signs of vitamin E deficiency in the young. He had also noticed considerable seasonal variations in the animals' powers of reproduction which did not appear to depend on changes either in the environmental temperature or in the exposure to light. Dr. E. KODICEK commented on the importance of the "animal protein factors" for reproduction, and Dr. L. J. HARRIS recalled early work by Mapson in which liver was found to contain "physin," a factor which improved the growth of young rats if given to their mothers during pregnancy.

Professor NIXON, summarizing the day's proceedings, hoped that pregnant women would continue to avail themselves of the dietary supplements recommended officially and provided through the Ministry of Food.

INCOORDINATE UTERINE ACTION IN LABOUR

At a meeting of the Edinburgh Obstetrical Society held on Feb. 9, with the president, Dr. E. C. FAHMY, in the chair, Professor T. N. A. JEFFCOATE read a paper on incoordinate uterine action in labour.

Professor Jeffcoate criticized the use of the phrase "uterine inertia" in view of the fact that many cases of incoordinate uterine action were associated with high muscle tone, especially in the middle and lower zones, or with violent spasmodic contractions, or with a constriction ring. The clinical picture was one of prolonged labour with slow dilatation of the cervix, despite the presence of strong uterine contractions and the absence of gross disproportion. Pain was unusually distressing and was felt predominantly in the back. It sometimes assumed a bearing-down nature before full dilatation of the cervix and in such circumstances appeared to arise as a result of spasm of the lower bowel. All degrees of the condition might be found, and, although he had defined it for the purposes of his present paper as developing in the absence of disproportion, yet there was no doubt that, when disproportion was present, incoordinate action of the uterus was particularly prone to occur as a complicating feature.

Professor Jeffcoate then reviewed 101 cases, 62 seen in private practice and 39 in hospital. The incidence in hospital cases was 0.6%. The condition was observed more often in private practice, but it was not possible to work out any very reliable figures of its incidence. The disease was almost entirely confined to primigravid patients, but the aetiological influence of advancing age had been exaggerated. Premature rupture of the membranes did not appear to be a direct cause, occurring in only 22 cases, while the disordered action of the uterus was recognized before rupture of the membranes in 56 cases. Even when the membranes were unruptured the uterine disturbance was sometimes sufficient to affect the foetus. The significance of the occipito-posterior position as a cause of incoordinate action had been confirmed, and delayed engagement of the head in occipito-anterior positions was noted frequently.

The maternal and foetal dangers of this incoordinate uterine action had diminished as a result of the introduction of chemotherapy, better general care, caution over anaesthesia, and a readiness to resort to caesarean section late in labour. Nevertheless, the dangers were still present, although in the two series no mothers died and the foetal loss by stillbirth and neonatal death was no more than 12%. Professor Jeffcoate said that but for caesarean section the foetal mortality might have been in the neighbourhood of 50%.

Remote Prognosis

A further series of cases had been investigated by Professor Jeffcoate in respect of remote prognosis; 140 severe but non-fatal cases requiring caesarean section or forceps delivery during the years 1936-46 were collected, but unfortunately it had been possible to trace only 91. Of these women more than one-third had decided to avoid further pregnancy as a result of their experiences. Only one-half had had further pregnancies. There was little difference between the caesarean section group and that in which forceps had been used in regard to this voluntary infertility, but all the women who had lost their first children tried subsequently to conceive; contraception was practised only by those who had a living child. A few women embarked on a further pregnancy only when promised that subsequent delivery would be by elective caesarean section. In general terms the follow-up showed that in a large proportion of cases the behaviour of the uterus was much more efficient in the second labour, and that whereas caesarean section might be necessary in the first labour there was a good chance of vaginal delivery in the second. The

ease of the second delivery appeared to be to some extent proportionate to the stage of dilatation reached by the cervix at the first labour. When full dilatation had been attained, the second labour was usually easy, even when the first baby had been delivered dead and with difficulty. It was therefore necessary to be cautious in advising elective caesarean section solely for "bad obstetric history."

In the management of disordered uterine action the administration of analgesics and antispasmodics, particularly morphine and pethidine, remained the chief line of attack. Professor Jeffcoate recorded generally disappointing results with the use of intravenous magnesium sulphate, of trinitroglycerin, and of oestrogens. After the intravenous administration of dilute solutions of oxytocin in glucose saline, as advocated recently by Theobald and others, two of Professor Jeffcoate's patients had suffered most severe pain without any change in the nature of the contractions, which remained incoordinate. Tetraethylammonium chloride had been tried in 11 cases, and had appeared in all to produce a strong and sustained uterine contraction, sufficient in one case to cause alarm for the foetus. When this contraction had passed off the patients experienced more frequent and apparently stronger uterine contractions for a period of up to one hour after the injection, but again there was no evidence of any alteration in the nature of the contractions, and in two cases constriction rings persisted.

Professor Jeffcoate briefly discussed the part played by nervous and emotional factors in the production of incoordinate uterine action. He was critical of the belief that fear and emotional tension were important in the aetiology in view of the fact that incoordinate uterine action did not recur in subsequent deliveries, even in those cases in which the first labour had been sufficient to daunt the stoutest heart. He thought that an unnatural resistance of the soft tissues of the lower part of the uterus might be found more important than neuromuscular imbalance resulting from fear. Professor Jeffcoate concluded by offering a classification of inefficient uterine action under the headings of (a) inertia proper, (b) incoordinate uterine action, and (c) cervical dystocia.

Professor Jeffcoate's paper was discussed by Dr. JOHN STURROCK, Dr. W. F. T. HAULTAIN, Professor KELLAR, Dr. HECTOR MACLENNAN, Dr. C. D. KENNEDY, Dr. T. M. ABBAS, Dr. J. A. CHALMERS, Dr. A. S. DUNCAN, Dr. W. I. C. MORRIS, and the president.

HEALTH CENTRES

In our account of a discussion on "Health Centres" at a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on March 7 (*Journal*, March 19, p. 494), Mr. W. T. DURNFORD, the architect, was misreported. Describing the new L.C.C. health centre at Stoke Newington, the architect is stated to have said that allowance would also be made there "for a certain number of private patients." What Mr. Durnford actually said was: "With 4,000 patients permitted at present, some overcrowding might result, but this number will no doubt be reduced in time, and the health centre was planned on the assumption that the number of registered patients per doctor might stabilize at 2,500, leaving a number of patients in the area to continue attending at private surgeries."

THE KING'S HEALTH

Uneventful Recovery

The following bulletin was issued from Buckingham Palace on Monday, March 21:

"The King's recovery from his operation has been uneventful. Instrumental tests have confirmed the substantial improvement in the blood-flow to the right foot, which had already been observed clinically after the operation."

Correspondence

Occupational Diseases of the Lens and Retina

SIR.—Professor Grey Turner (March 19, p. 497) is not quite correct in saying that Dr. William Robinson's communication received a "lukewarm reception." It was largely due to it that glass-workers' cataract was added to the schedule of diseases notifiable under the Employers' Liability Act. The Glass-workers' Cataract Committee of the Royal Society, of which I was then secretary, made a special visit to Gateshead to interview Dr. Robinson on the subject.—I am, etc.,

Leeds.

J. HERBERT PARSONS.

Classical Caesarean Section

SIR.—The lower-segment section was being performed at the Rotunda Hospital in 1909 when I was an assistant—i.e., 40 years ago. Professor J. Chassar Moir (March 5, p. 409) states it was introduced into "this country" 28 years ago. From an obstetrical point of view we consider that Great Britain and Ireland are one, and so I feel he is incorrect in the date he mentions for the introduction of the operation. Everyone agrees that the lower-segment operation should be done in nearly every case where caesarean section is indicated, but, as pointed out by several of your correspondents, there are exceptional instances where the classical operation must be the choice, and where the mentality of the obstetrician is still above suspicion.—I am, etc.,

Dublin.

BETHEL SOLOMONS.

Proguanil and Falciparum Malaria

SIR.—The recent criticism of proguanil ("paludrine") as a therapeutic agent in falciparum malaria is tending to obscure the fact that the drug when used in adequate dosage does give rise to radical cure of many strains of *P. falciparum*.

Over the last three years in Liverpool we have treated many uncomplicated cases of falciparum malaria with proguanil without reinforcement (100 to 300 mg. proguanil twice daily for 10 days). The disappearance of the parasites and the subjective improvement of the patients have been satisfactory in all cases. Follow-up has been difficult owing to the fact that most of our patients have been merchant seamen, but following the recent work on the Lagos falciparum strain we made a special effort and have managed to trace the subsequent history of 30 patients, the majority of whom had primary infections contracted in West African ports ranging from Dakar to Victoria. Three of these were followed up for 6-7 months, ten for 8-24 months, and the rest for 2-4 years.

There have been no relapses after treatment. These figures are small, but they surely indicate that over a fairly wide range of strains falciparum infections respond well to adequate proguanil treatment and that the likelihood of relapse in a random sample of strains is small.

Sir Gordon Covell and his colleagues (Jan. 15, p. 88) have demonstrated the failure of proguanil to bring about radical cure in neurosyphilitics infected with the Lagos strain, and have pointed out that there is a good deal of other criticism of the drug in the treatment of falciparum malaria. Some of these failures with proguanil have resulted from the inadequate treatment originally recommended (as one of us (B.G.M.) observed particularly in British West Africa), but genuine failures have undoubtedly been reported. It may therefore be advisable in view of the serious nature of falciparum malaria to reinforce proguanil in routine treatment with mepacrine, as suggested, especially in areas such as the West Coast of Africa where there may be non-reactive or resistant strains—some of the latter possibly developing as the result of previous inadequate treatment. We believe, however, that in the majority of uncomplicated cases proguanil unaided will both cure the clinical attack and give rise to radical cure.

Sir Gordon Covell's comments (Jan. 29, p. 192) on your leading article on proguanil are fully justified. On suppressive and therapeutic dosage toxic side-effects are of no importance.

In fact, as Afridi has pointed out, many patients have a very decided feeling of well-being while taking the drug.—We are, etc.,

Liverpool.

W. H. H. ANDREWS.

Treating the Aged Sick at Home

SIR.—I would like to draw your attention to a small omission in your excellent report (March 5, p. 408) of the recent meeting of the Medical Society for the Care of the Elderly.

When Dr. Brooke has received a report from his social worker he then arranges in many cases to meet the practitioner concerned to discuss the patient with him. Your report of the meeting gives the impression that the work is done by the social worker rather over the head of the general practitioner. I am sure this is neither the intention of the social worker nor the strict truth.—I am, etc.,

London, S.W.3.

AMULREE,
Chairman of the Medical Society for
the Care of the Elderly.

Punch Prostatectomy

SIR.—It was refreshing to read the interesting article by Mr. H. T. Cox on punch prostatectomy (March 5, p. 386). As the writer states, it is a pity that transurethral resection has received so little attention in this country, and the reason undoubtedly is the difficulty of learning and teaching an operation where the operator alone has the operative field in view. Once the technique is mastered, however, a perfectly performed transurethral resection of the prostate gives great satisfaction to both patient and surgeon.

No other operation can offer the patient so many advantages, but I must stress that it must be done perfectly. I think it is a pity that Mr. Cox laid so much emphasis on the adjective "subtotal" in connexion with resection; the more completely the obstructing tissue is removed down to the prostatic capsule the better the results, and most of the poor results of transurethral resection, such as haemorrhage, sepsis, and "recurrence," can be attributed to tissue left behind. As he mentions, in poor-risk cases the operation can safely be done in stages until the capsule is exposed, so that it is very rarely necessary to do a permanent suprapubic cystostomy.

The mortality rate for transurethral resection of the prostate by the punch method at the Mayo Clinic has for many years been around 1%. While working in another private clinic in the United States I performed the operation on a series of over 100 cases with no deaths, but here in Newcastle-upon-Tyne, where we have a large proportion of poor-risk public cases, we have never bettered 4%. It is evident that the better physical state of the private cases goes far to influence results.

Modern transvesical and retropubic prostatectomy offer little hazard in good-risk cases, are easily learned, and are more readily available to the general surgeon. Transurethral resection, although a more highly specialized procedure, offers to both good and poor risks the advantage of a "non-cutting" operation, with shorter hospital stay and quicker convalescence.—I am, etc.,

Newcastle-upon-Tyne.

JOHN SWINNEY.

Plasma-cell Mastitis

SIR.—May I comment on the recent correspondence in your columns on Dr. Max Cutler's article on plasma-cell mastitis (Jan. 15, p. 94) in order to make the point that the condition is rather an uncommon type of histological response in a common group of disorders of the breast, primarily involving the large ducts near the nipple and areola? The frequency of the disorders is to some extent concealed by the relative paucity of literature on the subject, probably due to the fact that the troubles they cause are often minor and self-limited.

If I may attempt to collect up some of the scattered threads, the underlying pathology would appear to be either atrophy of the breast at the menopause or hyperinvolution after lactation, so that the large ducts radiating from the nipple are left thinned and dilated. Sampson Handley had a beautiful illustration of the naked-eye morbid anatomical picture of the condition in his article on the breast in Choyce's *System of Surgery* (1932 edition), although concealed under the omnibus

title of "chronic mastitis." Sometimes the dilated ducts, while causing no symptoms, can be felt clinically, giving rise to the clinical picture which has been graphically described by Bloodgood¹ as varicocele of the nipple. Sometimes serous fluid accumulates in the dilated ducts; at other times the fluid and shed epithelium stagnant in the ducts tend to form an inspissated yellowish material, often resembling pus, which may discharge spontaneously or be expressed from the nipple. In either case the condition may lead to the patient presenting herself to the doctor as a case of discharge from the nipple.

Occasionally, but rarely, the inflammatory fibrosis around the stagnant ducts leads to retraction of the nipple—a feature which in the old terminology of breast disease used to be regarded as the exceptional example of the occurrence of nipple retraction in "chronic mastitis." In all the above examples there may be no palpable mass. But if there is sufficient inflammatory infiltration around the stagnant ducts a mass may be palpable clinically which has to be distinguished from other breast masses, if necessary by biopsy. The clinical picture is that of a predominantly periareolar mass, sometimes, but not always, with redness, tenderness, and other clinical inflammatory signs, the benign nature of which is often manifested by signs of its partial resolution.

There are two main histological pictures. The first is that of periductal mastitis,² of which Cutler's plasma-cell mastitis would appear to be a histological sub-variety. Mr. Colin D. L. Cromar (Feb. 26, p. 363) notes also the existence of intermediate grades in which plasma cells, although present, do not predominate. The other picture is one which Professor R. W. Scarff, of the Bland-Sutton Institute of Pathology of the Middlesex Hospital, has demonstrated to me both in personal cases and in those of colleagues; in this the inspissated, cheesy, and presumably fatty contents of the duct have burst through the degenerated duct wall and excited in the surrounding tissues similar histological reactions to those met with in fat necrosis—a picture apparently also noted by Mr. Cromar.

The above different clinical pictures may of course be combined, so that a single case may show, for example, both a nipple discharge, a mass, and nipple retraction. It is difficult to find a term to cover the whole group, but I would suggest that to emphasize the most important common pathological feature the term "duct stagnation" might be used. Suffixes such as "duct stagnation with periductal mastitis," "duct stagnation with periductal fibrosis," "duct stagnation with nipple discharge," might be added to emphasize the predominant clinical and pathological feature of the particular case.—I am, etc.,

London, W.

Blood Changes in Luminizers

SIR.—Dr. Ethel Browning (March 12, p. 428), in discussing blood changes in luminizers, makes the following statement:

"In the early stages the one consistent sign of overexposure is an absolute and progressive leucopenia, with a relative lymphocytosis causing an associated neutropenia or in some cases with a lymphopenia. This sign has been conspicuously absent in the luminizers examined between 1940 and 1947. The deviations in their blood picture suggest on the contrary a hyperstimulative effect, which appears to be produced by a mode of action entirely different from the depressive effect on the bone marrow of external gamma radiation."

Surely the findings of this paper are in accordance with the experience of all workers with x or gamma radiation. Chronic occupational exposure to these radiations produces the following effects on the blood:

1. The early responses are (a) an increase in the red cell count and in the haemoglobin value—both changes being very slight and associated with a slight rise in the colour index; and (b) little variation in the total white count but a relative lymphocytosis—up to 50% of the total white count. This early response is found in all workers with these radiations and occurs even if the radiation received is well within the accepted tolerance dose.
2. Later stages which occur include (a) leucopenia and a relative lymphopenia (when this occurs the worker should be removed forthwith from all exposure to any of these radiations); (b) still little change in the red cell count—the colour index being still slightly

raised; terminally the red cell count and haemoglobin values fall, by which time the worker is probably doomed to a severe and rapidly progressive aplastic anaemia.

These changes emphasize the absolute necessity of performing regular white and red cell counts on every worker exposed to these radiations. Only by this means is it possible to differentiate a normal count from one which has previously shown the earliest stages of response to radiation and is now falling into the later and dangerous stage. There are so many variations in each individual person that again one must differentiate by these repeated counts minor variations due to intercurrent ailments.

The results of the survey by Dr. Ethel Browning surely indicate the efficiency of the measures taken to protect these luminizer, from any harmful dosage of radiation. Had they shown absolute leucopenia or relative lymphopenia, then there would have been serious cause for alarm and revision of protective measures.—I am, etc.,

Worcester

ANTHONY A. VICKERS.

Ankylosing Spondylitis

SIR.—Dr. K. Sieher in his letter (March 12, p. 455) states, "The earlier the diagnosis is made the greater the success." He also emphasizes the value of a high total skin dose (2,500 r) of x rays. Our experience in the British Legion Unit of Rheumatology, and later when it became the Royal Free Hospital Unit of Rheumatology, is in full support of both these statements.

Drs. Gilbert Scott and F. Herniman-Johnson (March 12, p. 456), and Dr. N. R. W. Simpson and Surgeon Lieutenant C. J. Stevenson (Feb. 5, p. 214), all advocate the value of early x-ray examination of the sacro-iliac joints. So diagnostically significant are the x-ray appearances that I recommended in a recent report to the Director-General of Health, New Zealand, that radiological changes in the sacro-iliac joints could be made a proper subject of notification. I gave the opinion that this course would ultimately lead to earlier recognition, and consequently earlier treatment, of this crippling disease—a disease which appears to select the most normal healthy physiques and youths for its inroads. It should ultimately be possible to bring the principles of mass radiography to the sacro-iliac joints of all recruits, and possibly other categories, and so arrest this disease in its most responsive phase.—I am, etc.,

London, W.1.

C. B. HEALD.

Occupational Therapy

SIR.—In a review by Dr. Donald Stewart (March 5, p. 397) of a recently published book on occupational therapy the reviewer seems to have a misconception of the practice of occupational therapy. It is stated that "physiotherapists will be inspired to demand better accommodation and equipment . . .", that "those sections of the book on the treatment of special disabilities will be of wide help to physiotherapists." Whereas the physiotherapists, except for a few doubly qualified people, have not got the knowledge to practise occupational therapy satisfactorily.

The physiotherapist is more concerned with individual or group muscular action rather than with the more widespread physiology which is embraced in the planning and completion of a complicated set of movements. It is the physical medicine specialist, the occupational therapist, or an interested physician who is more likely to be concerned in the principles of occupational therapy, and not the physiotherapist.—I am, etc.

Edgware, Middlesex.

J. D. THOMPSON.

Self-administered Trilene Analgesia

SIR.—I feel that Dr. R. W. Cope (March 12, p. 454) and others who oppose the use of "trilene" by midwives are unduly apprehensive. No therapeutic agent which is used to relieve pain can be said to be completely safe at all times and under all circumstances.

Gas-air machines can get out of order and give too high proportion of gas to air, thus producing asphyxia. But cannot an apparently normal confinement "get out of order"? Does the midwife never have to send for medical aid? Even when the midwife sends for medical aid, does the young practitioner never ask the midwife what to do? I did many times, and we

very glad to take the midwife's advice. The midwife is trained to recognize the abnormal and to act skilfully in emergency.

We must acknowledge that the midwife is a colleague, and a very highly trained colleague too. She is not a half-witted subordinate, untrustworthy or unskilled. Most country doctors quite contentedly trust the midwife to administer chloroform anaesthesia for an instrumental delivery. And the country midwife soon becomes a very good anaesthetist from necessity. I have no doubt that there are far more fatalities during intravenous anaesthesia administered by a registered medical practitioner under favourable circumstances than occur under chloroform anaesthesia given by the midwife in country practice under most unfavourable conditions.

We are losing all sense of proportion in this argument as to what midwives should or should not use. The simple truth is that any recognized and well-established technique of pain relief is reasonably safe in the hands of those who have been trained to use it. It is equally unsafe in the hands of those who are untrained, be they medical practitioners, midwives, or motor drivers. Misfortune comes to the most skilful practitioner. In one hospital at which I worked two patients lost their arms following intravenous anaesthesia, given by a professional anaesthetist on the staff of a London teaching hospital, in a period of three months.

Having regard to the enormous increase in anaesthetic mortality and morbidity over the last twenty years we are in no position to throw stones at the midwives or to tell them that they are not to be trusted with pain-relieving drugs. Mr. F. Neon Reynolds (Sept. 25, 1948, p. 620, and Oct. 23, p. 671) and Dr. J. T. Hayward-Butt (Feb. 26, p. 364) have my support in strong measure.—I am, etc.,

New Barnet, Herts.

JOHN ELAM.

Trilene in the Oxford Vaporizer

SIR,—Dr. P. S. A. Heyworth's memorandum (March 12, p. 441) on the use of "trilene" in the Oxford vaporizer in the hands of midwives is of great interest to those of us who after qualifying aspire to practise domiciliary obstetrics.

For forceps delivery and other procedures the use of chloroform appears to be universal amongst general practitioners to-day, carrying out the induction themselves and handing over to the midwife for maintenance. Yet, as a final-year student who has completed a course in anaesthetics, I have yet to use or see used a drug which is apparently to be my constant standby in the years to come; and this lack of experience is not for want of pestering my seniors for opportunities to become acquainted with it.

From the report on Dr. Heyworth's 1,400 obstetric cases in which trilene was administered in the Oxford vaporizer it seems that this technique may well enable those of us who lack experience of the "rag-and-bottle" to face obstetric procedures with as much confidence as our forerunners. Trilene is a drug which we have ample opportunities of using during our clinical training both for first-plane anaesthesia and for analgesia in obstetrics. If its limitations for domiciliary use—i.e., its low volatility—can be overcome by the use of the Oxford vaporizer, we have surely a versatile and portable addition to our armamentarium.

Another contributor to the *Journal* has spoken of fatalities due to vagal inhibition during trilene anaesthesia. That this may form the basis of an argument against allowing midwives to use the drug is admitted. But surely there can be no questioning the lethal potentialities of a chloroform bottle in the hands of an inexperienced practitioner, and it is for this reason—and with a very personal eye for the future—that I express the hope that Dr. Heyworth's technique will be given the widest possible trial.—I am, etc.,

London, W.2.

JOHN A. RICHARDS.

Taking Children's Temperatures

SIR,—Being a Continental doctor I am astonished—and a little amused—about the discussion in the *British Medical Journal* on rectal temperature-taking. Nobody on the Continent—save perhaps a few "psycho-analysts"—would consider taking the temperature of small children anywhere else but in the rectum. "Nobody" does not refer to doctors only, but also to mothers of all classes, because "temperature-

taking" on the Continent is part of a mother's task if the infant seems "off colour." Whenever a doctor is called to a young child he is sure to ask the mother, "What is the temperature?" I have never met a mother who would either say that she has not a thermometer or that she does not know how to take the temperature or how to read it. That was a completely new experience for me when I started practising in this country.

But Continental mothers always take the "rectal" temperature of their young children. I do not suppose that a baby who has all his bodily needs cared for by the mother (including the care of his anal region) would perceive this act as "uncalled-for interference with parts which he prefers to be left alone."

For a young child, his several bodily orifices are of similar importance and of similar "sentimental" value. But things put in the mouth are expected to provide some sort of satisfaction in so far as they can be sucked and swallowed. From this point of view a thermometer proves a very unsatisfactory and frustrating instrument if put into the mouth and is far more likely to create a psychological upset than if it were inserted into the anus, where it only evokes the desire for expulsion, which will—after one or two minutes—be satisfied.—I am, etc.,

London, N.W.3.

LISE GELLNER.

Sexual Offenders

SIR,—The Report of the Joint Committee on Psychiatry and the Law appointed by the B.M.A. and the Magistrates' Association (*Supplement*, March 12, p. 135) is valuable inasmuch as it gives official recognition to what psychiatrists have stated for years. For example, I wrote in my book nine years ago:

"We would seriously state that imprisonment aggravates rather than cures homosexuality. Firstly, we have shown by the work of Jenkins that segregation from the opposite sex in rats tends to produce homosexual reactions and that these reactions do not always disappear after restoration of normal conditions. We have, however, much stronger evidence that such segregation is harmful. For example, Fishman investigated the sexuality of a prison population and found that as many as 30-40% were homosexual. He stated that the worst thing was that many young men reacted to prison by being initiated, in the abnormal atmosphere, into homosexuality. Although we have no statistics, experience of homosexual patients who have served prison sentences is that no improvement in their illness or behaviour results without psychotherapy."

It is nice to have official, if tardy, recognition of such facts. It is a pity, however, that the medical members did not have wider experience of the practical problems of paraphilia: their views appear to be based on theoretical rather than practical knowledge. For example, they perpetrate the old view that endocrine abnormality may be the basis of homosexuality. There is absolutely no evidence that this is so, although glandular disease may be a minor concomitant. The committee mentions "true perversion," but what is meant? It omits to define what entity it is describing. Neither is it stated what is supposed to be an "apparent perversion" or a "minor perverse trait." It implies that these supposed entities (which are extremely doubtful) can be differentiated by the ease with which they respond to treatment. Yet I have cleared up what has appeared to be a "true perversion"—if by that the writers mean someone who obtains sexual pleasure in an unbiological manner (i.e., without the possibility of fertilization because of abnormal relationship)—in a few sessions, whereas what has appeared to be an "apparent perversion" has proved obstinate and difficult.

The statement that treatment rather than imprisonment is the best thing for both the public and the offender is one with which everyone must agree. The problem from the practical point of view is, however, that there are so few places where it can be obtained. The ordinary psychiatric out-patient department is most unsuitable, and the few clinics where psychotherapy is available are overwhelmed with neurotics. In any case the treatment of the pervers is a specialized matter. If he cannot afford private treatment it is almost impossible for him to be cured.

I think that the time has come when an institute of psychosexual diseases should be established in London and these unfortunate people be given a real chance of cure. Otherwise

it is but a case of punishing a man for being ill without giving him the means of being cured. If I may alter Omar Khayyám:

Oh, Thou, who didst with Pitfall and with Gin
Beset the Road I was to wander in,
Thou wilt not with stern Legislation round
Enmesh me, and impute my Fall to Sin?

—I am, etc.,

London, W.1.

CLIFFORD ALLIN.

Institute of Social Psychiatry

SIR,—May I draw your attention to the fact that in your leading article on Group Psychotherapy (Feb. 5, p. 227) you made no reference to the pioneer work or publications of the Institute of Social Psychiatry?

This Institute is the outcome of the work carried out by Dr. J. Brier and others during the last two or three years. A book entitled *Therapeutic Social Clubs* was published for the Institute of Social Psychiatry by H. K. Lewis & Co., Ltd.; it was edited by Dr. J. Brier and contained an introduction by Dr. E. B. Strauss. The following articles have also been published:

"Psychotherapy in Mental Hospital Practice" (*J. ment. Sci.*, 1940, 86, 928), "Group Psychotherapy" (*British Medical Journal*, 1942, 1, 214), "A New Form of Group Psychotherapy" (*Ment. Hlth Lond.*, 1944, 5, 23), by Dr. J. Brier. "Group Psychotherapy of War Neurosis" (*Lancet*, 1943, 1, 204), by Dr. D. Blair; and "Mass Psychotherapy" (*Lancet*, 1940, 2, 769), by Dr. E. N. Snowden.

No reference was made in your leader to any of the above, which, as you will note, are amongst the earliest publications on this subject, but I feel sure that this must be an oversight on the part of the writer and that he would not wish to exclude mention of some of the pioneer work in this field in England.—We are, etc.,

JULIAN SNOW.

Hon. Secretary, Board of Governors,
Institute of Social Psychiatry

NOEL HARRIS.

Chairman, Academic Committee

London, N.W.3

Anuria

SIR,—I thank Dr. J. F. Heggie (March 12, p. 454) for replying to my letter (Feb. 12, p. 282); but he thinks I have misread him and thus misinterpreted his meaning. I quoted him accurately, and I thought sufficiently; but even now he does not answer my criticism. He states that the intralobular arteries are "very fine straight branches," whereas the interlobular arteries in the juxtamedullary region of the cortex are large, so that when a vasoconstriction occurs the former are the more affected.

This is not an explanation: it is a statement, and I query the statement. And he creates a difficulty. He writes: "This abrupt division of comparatively large arteries into very small ones which are really end-arteries (since they give off the different glomerular arterioles) provides for the relatively high pressure necessary for filtration in the glomerular vessels." But I should have thought that if a relatively high pressure of moving blood within glomerular capillaries is necessary for the appearance of water in Bowman's capsules the arteries and arterioles supplying those glomeruli would have been relatively big, and the juxtamedullary interlobular arteries (or the arterioles in which I suppose they end), supplying juxtamedullary glomeruli (often degenerate, according to Trueta and his co-authors¹), would have been relatively small.

Unfortunately Dr. Heggie has not referred to the second part of my letter in which I pointed out, quoting Brodie, that the secretion of urine has a profound effect on the flow of blood through the kidney. It is the key to an understanding of puerperal anuria and to the very marked oliguria of eclampsia, as I showed in a paper published in 1929.² In that I stated that "the distension of the cortical tubules is the primary change." Evidence of this was given on Jan. 21, 1949, at a meeting of the Section of Obstetrics of the Royal Society of Medicine, when sections of the kidney from two different cases of puerperal anuria obtained from the living patient were displayed on the screen: the distension of the cortical tubules was the overwhelming feature. This demonstrates that the

anuria is not due to a primary constriction of peripheral cortical arterioles—the urine comes from the blood, and if no blood reaches the glomeruli and the tubules no urine can be formed and no distension of tubules could occur. There is another point to mention. On March 2, 1949, at a meeting of the Section of the History of Medicine at the Royal Society of Medicine, Professor Winton stated he had repeated Brodie's experiments and had confirmed his results: he also made some other valuable statements bearing on this question.

The evidence is—and successful treatment supports it—that cortical necrosis occurring in association with puerperal anuria is simply the result of an intrarenal obstruction to the exit of urine. Obviously if the kidney is so compressed that the urine formed in the cortex cannot traverse Henle's tubules, with their hairpin corners in the medulla, the same effect as that caused by clamping the ureter in the experimental animal (or by its ligation in man) will occur—the kidney will become almost bloodless. That such a compression of the kidney occurs in concealed accidental haemorrhage obstetricians may perhaps allow. It is the primary change. After delivery (emptying the uterus) other forces operating within the kidney, to which I referred in my 1929 paper, come into play, explaining the tendency of the anuria to persist.—I am, etc.,

Renal Lesions Associated with Pregnancy

SIR,—In your report of the meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine (Feb. 12, p. 281), I am quoted as describing the morbid anatomy of "uraemic cortical necrosis." I should like to point out that I never used this phrase, and, in consideration of the context of your report, the term "lower nephron nephrosis" should be substituted. Since I argued that bilateral cortical necrosis and lower nephron nephrosis were distinct pathological entities the distinction is of some importance.—I am, etc.,

J. F. SMITH

POINTS FROM LETTERS

Occupational Therapy and Physiotherapy

Mrs. Z. C. GROUNDERS-PRICE (Edinburgh, 4) writes: I read with interest the review by Dr. Donald Stewart of *Principles of Occupational Therapy* by Willard and Spackman (March 5, p. 397). I am glad to learn of his enthusiasm for work of this nature. It is, however, somewhat discouraging to realize that even he fails to appreciate the distinction between occupational therapy and physiotherapy. This is clear from his suggestion that "the author's description of the ideal organization of a hospital department of occupational therapy may well inspire physiotherapists in Great Britain to demand better accommodation and equipment and a more important place in the hospital hierarchy." May I call your readers' attention to the fact that in Great Britain there are separate training schools both for occupational therapists and physiotherapists, and that a diploma in occupational therapy is awarded after satisfactory completion of a course of 2½–3 years' duration at a training school recognized by the Association of Occupational Therapists in England and the Scottish Association of Occupational Therapists in Scotland?

Value of Clinical Records

Mr. GEORGE JENNINGS (Huddersfield) writes: The greatest experiments in the realm of medicine are conducted by clinicians—G.P.s and specialists—in the treatment of their patients. In many of our hospitals, owing to inadequate records and classification, invaluable evidence is lost every day—evidence which in the hands of competent investigators might be of inestimable value in assessing the value of treatment. In planning surgical treatment one is continually wondering what would be the fate of, say, 1,000 patients in ten years if such and such a treatment were carried out. It is idle to theorize or to plan purely according to mechanical considerations when the answer to such a question should be available. Every patient undergoing an operation should have an account of his complaints and clinical condition; a special operation form attached to the above notes must contain the pathological findings and nature of the operation. Reports of x-ray and laboratory findings should be appended. If this can be done, provided no attempt be made to turn the house-surgeon into a clerk, then untold advantages may accrue. Encouragement would be given to the writing of good notes, surely the handmaiden of good clinical work. This matter should surely be planned and executed on a national basis by the profession.

Obituary

J. R. T. CONNER, M.D.

Dr. J. R. CONNER, who was editor of the *Clinical Journal* for more than thirty years, died on March 16 at the age of 87. John Richard Tarrant Conner was a student at Queen's College, Cork, and St. Thomas's Hospital. He took his M.D. with honours in 1882, and from then onwards his chief interests lay in medical journalism. For over thirty years he was in sole editorial control of the *Clinical Journal*. He pursued a policy of providing his general practitioner readers with articles and information that were essentially clinical and often written by well-known specialists. If he could not always obtain original articles he reprinted the best from other journals, and he abstracted widely and well under the heading of "Medical Progress." The standard he maintained was high. He was an individualist and knew just what he wanted. He had very definite ideas about how an article should be written, and used his blue pencil freely. Some of his contributors objected, but there could be no denying that by the time he had finished with it the article was improved. His indexing, of which he made a specialty, was a model of accurate detail.

Though he lived for the *Clinical Journal* he had other interests. For many years he was the London correspondent of the *Journal of the American Medical Association*, and he contrived to provide an informative column at almost weekly intervals. Many English readers of the *J.A.M.A.* found his "London Letter" one of its most interesting features. Latterly he had much to write about the working of the National Health Service Act, but he tended to allow his political sympathies to run away with his judgment. He was an uncompromising anti-socialist and a Southern Irishman who loved an argument. He must have enjoyed writing his last letters to America every bit as much as they were appreciated over there, for he recounted with vigour and obvious relish the teething troubles of the Act.

For a man of 87, J. R. Conner—he omitted the T. in his signature—was remarkably active both physically and mentally. He read widely and had a retentive memory. He was surprisingly well informed on trends and progress in modern medicine. To talk to him was to improve one's knowledge, and he delighted in making the long journey to the West End of London from his home in Greenford in order to meet and discuss things with a friend. He feared neither inclement weather nor the busiest traffic.

He died as he would have wished, suddenly and in full harness. He leaves a widow—a woman of Irish charm, who has been a great help to him—and a son.—W.B.

Dr. R. Y. Stones, Chester, writes: It is with sorrow that one heard of the passing of that great athlete and sportsman, A. W. Wakefield. In the obituary notice of March 19 (p. 504) no mention is made of his swimming. In this he was proficient, and represented his hospital and the United Hospitals Swimming Association, of which he was captain, in water-polo, diving, and racing. He was a member of the Amateur Diving Association. The tribute mentions that he was a severe disciplinarian. This discipline included sternness to himself, as was shown when he broke his olecranon through diving, I believe, into unexpectedly shallow water. He had the bogue wired, and within a day or two he was boxing—"A.W.'s" method of preventing stiffness in the joint.

The Services

AUXILIARY R.A.M.C. FUNDS

The annual general meeting of members of the Auxiliary R.A.M.C. Funds will be held at 11, Chandos Street, London, W., on Monday, April 4, at 5.30 p.m., when the report and accounts for 1948 will be received and officers and auditors for 1949 appointed.

Colonel (Local Brigadier) A. G. Harsant, O.B.E., late R.A.M.C., has been appointed Honorary Surgeon to the King in succession to Colonel James Biggam, M.C., retired.

Medico-Legal

ACTION FOR NEGLIGENCE IN DIAGNOSIS

Mr. J. B. Hunter's Appeal Allowed

Mr. James Forbes Whiteford, an American citizen and a consulting engineer, was awarded £6,300 damages in an action¹ in which he alleged negligence against Mr. John Bowman Hunter, M.S., F.R.C.S., and Dr. Seymour R. Gleed, a medical practitioner of Finchley. Mr. Justice Birkett dismissed the action against Dr. Gleed, holding that no negligence could be attributed to him. Mr. Hunter subsequently appealed against the decision of Mr. Justice Birkett, and Mr. Whiteford cross-appealed against the dismissal of Dr. Gleed from the case. Mr. C. R. Havers, K.C., and Mr. Henry C. Dickens, instructed by Messrs. Hempsons on behalf of the Medical Defence Union, appeared for the defendants; Mr. Richard O'Sullivan, K.C., and Mr. Robert Fortune, instructed by Messrs. Billinghurst, Wood and Pope, for the plaintiff.

Lord Justice Asquith,² in allowing the appeal by Mr. Hunter, said that it was patent from the evidence that Mr. Hunter had been mistaken in his diagnosis of cancer of the bladder on April 5, 1942. It was not, however, every slip or mistake which imported negligence. It was alleged that Mr. Hunter was negligent in not verifying his diagnosis by cystoscopy or by biopsy. On the question of cystoscopy it appeared to the Court decisive that, once it had been decided on April 5 to open the plaintiff's bladder, cystoscopy became entirely unnecessary. On the question of biopsy Mr. Hunter had given three reasons for not resorting to this procedure. His Lordship discussed the arguments for and against biopsy in detail and took the view that Mr. Hunter was not negligent in his decision not to carry out biopsy. It followed that the appeal must be allowed.

Mr. Whiteford's cross-appeal against the dismissal of his action against Dr. Gleed, which had not been strongly pressed, was dismissed. Leave was given to appeal to the House of Lords.

A fuller account of this important judgment will appear in a subsequent issue.

Medical Notes in Parliament

ANALGESIA IN CHILDBIRTH

On March 15 Mr. BEVAN asked the permission of the House to make a statement on analgesia in childbirth. The debate on the second reading of the *Analgesia in Childbirth Bill*, which was moved by Mr. Peter Thorneycroft on March 4, was reported in our issue of March 12 (p. 459).

The Minister of Health said that at the end of 1947 more than 7,000 of the 16,000 midwives then practising were trained in the administration of analgesia. During 1948 practising midwives were trained at the rate of 240 per month, and at this pace training would be completed in two years. If the Central Midwives Boards at any time considered that they needed to make further rules in the matter, the boards already had ample powers in the Midwives Acts. The number of cases in which analgesia was administered by midwives had also increased greatly. In 1938 analgesia was administered by domiciliary midwives in England and Wales in less than 1,200 cases; in 1944 it was administered in 5,100 cases, while in 1947 domiciliary midwives were able to give this relief in almost 44,000 cases. Returns for 1948 were not yet complete, but those so far received showed that in the 72 areas to which they relate good progress was again made. In these areas analgesia was administered in 16,500 cases in the six months of 1948 during which the National Health Service was in operation as compared with 9,100 cases in the last six months of 1947. It was the Government's policy and determination to secure that full facilities were provided as quickly as possible for women to have analgesia in childbirth, and much progress had already been made. In so far as it was necessary to ensure that sufficient analgesic apparatus and drugs were provided for the use of domiciliary midwives employed in the

National Health Service, that the apparatus was maintained in a proper state of efficiency, and that facilities for transport were provided, he was satisfied that he had all necessary powers to place a duty on local health authorities in these matters.

Part III of the National Health Service Act required local health authorities to carry out a number of duties relating to local health services, including duties to make arrangements for the care of expectant and nursing mothers and to secure that sufficient midwives were available for attending domiciliary confinements. Local health authorities were further required to carry out these duties in accordance with proposals submitted to and approved by the Minister of Health or, in Scotland, the Secretary of State, who might before giving approval modify them and might at any time require the submission of revised proposals. In submitting their proposals for approval most local health authorities included provisions relating to analgesia. Where they did not do so, or the Ministry of Health thought the provisions were inadequate, the proposals were altered before being approved. Thus duties had already been imposed on local health authorities in this matter.

The National Health Service Acts had placed upon the Minister and the Secretary of State the duty of providing an adequate hospital service, and by reason of this duty an obligation rested upon them to see that proper arrangements were made for the administration of analgesia in their hospitals. Mr. Bevan added that he was sure that the views spoken with such sincerity in the recent debate would be carefully observed by those authorities, both local health authorities and hospital authorities, which were concerned with the care of women in childbirth, and would create in them also a determination to see that there was no delay or hindrance in making that full provision which was desired.

Mr. THORNECROFT thanked Mr. Bevan for his statement and gathered from it that the Minister did not regard the Analgesia in Childbirth Bill as necessary. Mr. Thorneycroft questioned whether it was possible by regulation to turn a permissive power into a public duty. The National Health Service Act did not prescribe a duty to provide an analgesia service. He declared he would endeavour to bring the Analgesia Bill into law.

Mr. BEVAN replied that there was no statutory limitation and therefore no need for statutory easement. Limitations were imposed by Nature, by resources, and by the state of medical knowledge. The Minister of Health and the Secretary of State had power to modify, change, and enlarge any duties imposed on local health authorities. That included power to impose the duty of using analgesic apparatus or any other apparatus medically useful in alleviating pain in childbirth. He was not prepared to select out of a general service one matter for priority.

Colonel STODDART-SCOTT asked whether the Minister intended to use his power to place on local authorities a duty in these matters. Was Mr. Bevan aware that one local authority in Wales—Newport—would not permit a midwife to have a motor-car?

Mr. BEVAN said that in Newport the analgesic apparatus was sent by ambulance. The figure he had given of 240 midwives trained every month in the use of the apparatus was for Great Britain.

Colonel GOMME DUNCAN asked for the figures for Scotland.

Mr. WOODBURN said that in Scotland in most maternity cases doctors were available and had powers to use whatever methods were necessary for relieving pain.

Further Debate Suggested

Mr. ERIC FLETCHER on March 17 asked whether Mr. Morrison proposed to give time for consideration of a motion on the Order Paper advocating that the Government should provide time to facilitate consideration of the Analgesia in Childbirth Bill.

Mr. HERBERT MORRISON said Mr. Bevan had dealt with the matter. Mr. Morrison thought the Minister's statement fully justified. He did not think there would be any advantage in a debate.

Mrs. MANNING pointed out that Government supporters were associated with the Bill and had not withdrawn their names from the motion.

Mr. MORRISON, continuing, said he could not add to what Mr. Blenkinsop and Mr. Bevan had said in previous discussions.

ARTIFICIAL INSEMINATION AND LEGITIMACY

LORD READING, in the House of Lords on March 16, called attention to the effects of recent judicial decisions on the legitimacy of children. He said the Matrimonial Causes Act of 1937 laid down that wilful refusal to consummate a marriage should be a ground for nullity. It also introduced as grounds on which a marriage could be declared null and void the

ground that one of the parties had been of unsound mind when the marriage took place, or that one of the parties suffered from venereal disease at the time of the marriage, or, in the case of a woman, that she at the time of the marriage had been pregnant by some man other than the husband.

In a case brought in 1942, after the parties had lived together for thirteen years and a child had been born, a petition again: the husband was met with the reply that the marriage had never been consummated in spite of the fact that a child had been born which by common consent was the child of the husband and the wife. The husband asked for a decree of nullity, and the judge came to the conclusion that the marriage had never been consummated by actual penetration and that the child had been conceived by an accidental process of fecundation from without. In a second case a child was conceived before the marriage but born after the marriage took place. Seventeen years later the husband filed a petition of nullity on the ground that the marriage had never been consummated because of the wife's wilful refusal. The judge made the decree, with the result that the child, then 17 years of age, was made a bastard.

LORD READING then turned to the separate and more controversial issue of human artificial insemination. He believed it was increasingly practised, and he mentioned the case in November, 1948, of a woman married in 1940 to a man whom she found to be unable to consummate the marriage. That woman, towards the end of 1947, had herself artificially impregnated with the husband's consent and through his agency. She left him in January, 1948, and in September a child was born. Two months later a decree of nullity was granted on the ground of the husband's incapacity. There had been no penetration, but there was a child of the father and the mother, yet the decision of the judge to grant a decree was inevitable as the law stood. Artificial insemination by a donor raised even more complex questions. The view expressed by a legal authority that artificial insemination by a donor constituted adultery required further consideration. It would be an irrational situation if, after artificial insemination by a husband, a marriage could be annulled, whereas extra-marital intercourse of the same kind could be put forward as adultery. In the case of artificial insemination by a donor, whose name, in the declaration made of the birth of a child, was to be put in as the father? It might be that a doctor would find himself involved in a charge of conspiracy as well as of perjury.

The position of the medical profession in this matter was one of immense delicacy and responsibility. He had seen it suggested that artificial insemination by a donor should be made a criminal offence. That would be a fatal error. It would drive the practice underground and force it into clandestine and uncontrolled use. He pressed the Government to appoint a Royal Commission or a Departmental Committee to go into every aspect of this difficult and debatable matter.

LORD BRABAZON OF TARA, who had a motion on the paper calling attention to the social problems resulting from human artificial insemination, referred to the document on the subject which had been issued under the authority of the Archbishop of Canterbury. He said it was axiomatic that a child born as a result of A.I.D. must be illegitimate as it was not the child of the two spouses; but he cited a case in the Supreme Court of New York State in which the child had been declared legitimate and the husband the legal father. It appeared to Lord Brabazon that anyone who wished to be a donor must be a megalomaniac of the first order, and he did not think that in this country many would be found who would consent to be donors. He hoped that if they were discovered they would be ostracized. Children engendered by artificial insemination were as genuinely born as any others and should not be called "test-tube children." He thought it true that such a child was unlikely to suffer psychologically, but there were no real data on which to judge.

A.I.D. as a Criminal Offence

THE ARCHBISHOP OF CANTERBURY said artificial insemination was a practice far less widespread in this country than in the United States, but it was established here on a small scale. Artificial insemination by a husband was, on the whole, justifiable. Artificial insemination by a donor was contrary to Christian standards. All those concerned with A.I.D. accepted that the donor should remain unknown to anybody but the doctor concerned, but when the child was registered and the nominal father registered himself as the real father that was a criminal offence under the Perjury Act, 1911, for which a sentence of seven years' imprisonment might be imposed. This falsity in the declaration of paternity raised legal points connected with titles, estates, interests, or funds. Either the law must be altered to allow relief from perjury to the nominal father or A.I.D. should be made a criminal offence. The doctor assisted at an act which to his knowledge would involve perjury. The Archbishop was perturbed that the Medical

Nearly home . . .

but it seems like miles

Doctors today find that a large number of their patients complain of constant tiredness, of 'finding everything too much', of 'feeling generally run down'. Cases of debility and lassitude caused by present-day conditions are becoming increasingly prevalent. For these conditions 'Vibelan' is of particular value. It counteracts B vitamin deficiencies, containing as it does the principal members of the B group in the balanced proportions which are necessary for effective utilisation of proteins, fats and,

more especially, carbohydrates. Each tablet contains vitamin B₁ 0.5 mg., riboflavin 0.75 mg., nicotinamide 7.5 mg., in a yeast extract base. Four tablets provide the normal daily requirement of these vitamins. 'Vibelan' is available in bottles of 50 tablets. Further details are available on request.

Aci-jel
FOR VAGINITIS

Investigators^{1, 2, 3} characterize a buffered acid jelly as one of the simplest and most direct forms of effective therapy in vaginitis and cervicitis.

Clinically, the re-establishment of a normal vaginal pH (4 to 4.5) proves "extremely useful,"⁴ because it encourages "the elimination of pathologic organisms and the

growth of normal vaginal flora consistent with the healthy vagina."

Aci-jel affords the physician a water-miscible, buffered acid jelly which is entirely non-irritant and may be used with safety over prolonged periods. It is available in 3½ oz. tubes, with or without measured applicator, for professional use or prescription.

HEPASTAB FORTE

HEPASTAB FORTE is a highly concentrated extract of liver which has been prepared in our Nottingham laboratories as the result of research conducted by our own chemists in co-operation with clinicians in this country and abroad. It contains all the known anti-anæmic factors of liver, is highly refined, painless on

injection, and highly concentrated. Each 1 c.c. of Hepastab Forte is obtained from 100 G. of liver and is therapeutically equivalent to 4,000-5,000 G. of fresh liver by mouth.

Ampoules of 1 c.c.: single ampoules, boxes of 3, 6 and 12 ampoules. Rubber-capped vials of 10 c.c.

Literature and further information gladly sent on request to Medical Department.
BOOTS PURE DRUG COMPANY LIMITED, NOTTINGHAM, ENGLAND.

the VITAMIN appetite of the VERY YOUNG

Even the baby weighing less than fifteen pounds needs almost half as much vitamin A as the adult of fifteen stones. In terms of vitamin D, infant requirements are more than *twice* those of the average grown-up. That is why administration of Adevolin Liquid is so often adopted as a routine measure for infants, helping to ensure that their need for these two vitamins is properly met. Twelve drops daily—two or three drops at each feed—are quite sufficient. For the mother, Adevolin Capsules provide a convenient means of supplementing the dietary intake. The simple routine of one capsule daily throughout pregnancy can significantly reduce the risk of infection and lessen the incidence of toxæmia and caries. Moreover, a satisfactory maternal level of Vitamins A and D is clearly of great benefit to the orderly development of *fœtal* tissues.

Liquid. Each cc contains 12,000 i.u. vitamin A and 2,000 i.u. vitamin D.
Capsules. Each capsule contains 4,500 i.u. vitamin A and 900 i.u. vitamin D.

Defence Union should have given advice to medical practitioners concerned in this practice on how to protect themselves professionally against adverse legal consequences to themselves in connexion with this practice. If A.I.D. were made a criminal offence, then no doctor could employ it without losing his professional standing and without himself becoming liable to charge. The only effective way to prevent the practice was to forbid the doctor to employ it. Commenting on a recent case in the Probate and Divorce Division, the Archbishop said that presumably any couple who had children born by A.I.H. and *a fortiori* by A.I.D. could get a nullity decree if they desired it. He contended that where through the impotence of one party there was a mutual surrender of the reproductive organs, though not of the sexual organs, that, surely, was consummation of the marriage. By the same argument, A.I.D. was adultery. Lord Dunedin in *Russell v. Russell* had said fecundation *ab extra*—from another party—was adultery. The suggestion that A.I.D. should be employed to enable unmarried women to bear children was on all grounds to be rejected. The only two countries which had in recent times encouraged this practice were Nazi Germany and Soviet Russia. In the interests of society, of the family, and of the child A.I.D. should not be permitted. The practice became yet more degrading when the semen was derived from what the Medical Defence Union described as a "bureau" or "bank."

Fraud and Secrecy

Lord MERRIMAN said sexual intercourse, in the ordinary sense of the word, was necessary to constitute adultery. How far it proceeded was another matter, but the man and the woman must be personally concerned. A whole range of cases showed that adultery might be regarded as proved though penetration must have been very slight. Once the court got to a state of doubt created by evidence of virginity, a heavy additional burden was thrown on a husband who asserted that adultery had been committed. Artificial insemination was increasing and ought to be diminished. What was to happen in the next generation? The Medical Defence Union said it was prepared to limit the number of inseminations from one donor at one time to 100. This meant that in the practice of one doctor a man might sire 100 boys and girls at one time. What was to happen when these half-sisters and half-brothers fell in love with each other twenty years later? The whole essence of A.I.D. was fraud and secrecy. The undertaking exacted by the Medical Defence Union that no question of property was involved was not worth the paper on which it was written. The sooner the medical profession became aware that by lending themselves to false statements in the register they might become liable to a charge of common law misdemeanour or of conspiracy the better it would be.

Replying to the debate, Lord CHORLEY said that the situation which existed under the Act of 1937 called for treatment. On the other hand, questions of property rights and all sorts of other problems were involved and he would be wrong to undertake that immediate legislation would be introduced. By those who advised the Government on legal problems it was regarded as far from clear that artificial insemination by an outside donor amounted to adultery. The Government agreed with the view that to make A.I.D. a criminal offence would drive it underground. At present the practice was being pursued under medical supervision, which was probably the best which could be devised. To make it a criminal offence would shock a large number of people. The problem was dominated by the question of fertility in marriages, and till the Report of the Royal Commission on Population was published, which would probably be in the next few months, it was impossible to come to any satisfactory conclusion on this matter. Until the Government got that Report it would be wrong to set up a new Royal Commission or Departmental Committee. The Lord Chancellor, Lord Chorley said, thought that questions of legitimacy and inheritance arising from artificial insemination would not be numerous and would be most satisfactorily dealt with by the courts as they arose.

Lord READING remarked that he had seldom heard a more unsatisfactory answer given to a serious debate in the House of Lords.

Lord ADDISON promised that without delay consideration would be given to what had been said in the debate.

Exchange Control Medical Advisory Committee

Colonel STODDART-SCOTT said on March 14 that treatment for some diseases could not be obtained in this country. From time to time medical pioneers who worked abroad were prepared to undertake cases which lesser men would give up as incurable. When a doctor or specialist decided that the only

treatment which would do good was treatment in a foreign country the patient then had to apply to the Exchequer for permission to receive foreign exchange; 914 cases were refused foreign currency for treatment abroad in 1948 although that treatment had been recommended by a doctor or a specialist. The Chancellor always said that he had been advised by the Exchange Control Medical Advisory Committee that foreign currency should not be granted. This committee included ten medical members who each received yearly for their services £500. The House had never been told who composed the committee. Was the reason that it was composed of medical nonentities? Probably it was composed of distinguished consultants. If they were distinguished consultants, why did the country not know who they were? Disclosure would reduce the unrest among members of the medical profession, who disliked to see their recommendations, made after full investigation and examination, turned down by a committee which had never seen the patient.

Mr. DOUGLAS JAY, replying for the Treasury, said there was no question of refusing currency to anyone who as a result would improve his chances of recovery. The question was how to decide which individuals fell into that category. In running an exchange control system that decision had to be made and the Treasury could not make it. The objection to letting the doctor of the individual make the decision was not that anyone questioned the medical facts stated by the patient's doctor. The Exchange Control Medical Advisory Committee accepted those facts from the doctor. Having accepted those facts, its function was to decide whether a case was established for the patient to travel to a specified country in order to obtain special treatment. They should apply common standards in deciding what medical facts justified the journey suggested. The suggestion that the committee should see the patient misconceived the committee's functions. That would be a checking of the veracity of the statement made by the patient's doctor. Experience before the present arrangement came into force had given little evidence that common standards would be applied without the procedure of the Advisory Committee.

The previous system had led to abuses which were liable to cost a great deal in foreign exchange, and some check had to be introduced. The present check was working well. The Advisory Committee consisted of ten leading specialists in tuberculosis and other diseases in addition to the chairman and secretary. The names had not been given because that was not the desire of the medical profession or of the members of the committee. Every case was studied by two members of the committee, who in the event of disagreement referred it to the chairman, and the fact that the committee as a whole had not met in a certain period was irrelevant. The committee was always willing to reconsider any case if fresh medical evidence was brought forward. Figures showed the cases were dealt with in a sympathetic manner. For many of these cases treatment was available within the sterling area. In 1948 2,907 applications had been made and nearly 2,000 were granted; of tuberculosis cases 101 were refused and 1,009 were granted.

Colonel STODDART-SCOTT then contended that the only way to avoid abuse was for every patient to be seen, and he said that the committee if it failed to see a case was sure to make mistakes.

Mr. JAY remarked that Colonel Stoddart-Scott was impugning the veracity of the medical profession by implying that the diagnosis of the patient by the ordinary practitioner could not be relied on. He thought that in the great majority of cases one could rely on the ordinary doctor for statements of fact.

Hospital Accommodation in Northern Ireland

In the Northern Ireland Parliament last week Mr. HANNA asked the Minister of Health and Local Government whether he could state the total number of beds available for patients in general hospitals in Belfast and Northern Ireland at the date of the coming into operation of the Health Services Act and at the present time.

The Minister replied that on July 5, 1948, the total number of beds available in general hospitals vested in the Northern Ireland Hospitals Authority was: Belfast, 3,170 beds; Northern Ireland, excluding Belfast, 3,204 beds. The total number of beds available in general hospitals on March 10 was: Belfast, 3,280 beds; Northern Ireland, excluding Belfast, 3,344 beds.

Lepers in Nigeria.—It is estimated that there are about 400,000 lepers in Nigeria; 37,000 are receiving hospital and similar treatment; 33,000 are out-patients. Leprosy is compulsorily notifiable only in districts contemplated under the law governing the isolation and detention of lepers.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

M. M. Bull, M.B., B.Chir., has been appointed a University Lecturer in Anatomy for three years from April 1.

The following medical degrees were conferred on March 12:

M.D.—S. F. Logan Dahne.

M.B., B.Chir.—N. Allsup, *W. Beautyman, A. E. Neill.

* By proxy.

UNIVERSITY OF MANCHESTER

On Founder's Day, May 18, the honorary degree of D.Sc. will be conferred on Alfred Ernest Barclay, D.M., F.R.C.P., Honorary Radiologist and Acting Director, Nuffield Institute for Medical Research, Oxford, for his contributions to medical research, and on Katherine Hope Coward, D.Sc.(Lond.), Reader in Biochemistry and Head of the Nutrition Department in the School of Pharmacy, University of London, for her educational and scientific services.

Alexander William Gordon Ewing, M.A., Ph.D., has been appointed Ellis Llwyd Jones Professor of the Education of the Deaf and Director of the Department, from March 25.

Medical News

King Thanks Hospital Board

The thanks of his Majesty the King have been conveyed to the South-Eastern Regional Hospital Board and to the board of management of the Edinburgh Royal Infirmary for their kindness in granting leave of absence to Professor J. R. Learmonth, Dr. John Gillies, Mr. A. J. Slessor, and Miss Gordon, theatre sister in the Royal Infirmary, so that their services might be available to him in his recent illness. The chairman of the South-Eastern Regional Hospital Board has received a letter signed by Sir Alan Lascelles, his Majesty's Private Secretary. His Majesty also pays tribute in it to the skilful treatment and care he has received, and expresses his thanks to the Royal Infirmary for providing and preparing equipment for his operating theatre at Buckingham Palace. The equipment referred to is the personal instruments of Professor Learmonth and his team. These were prepared and sterilized at the Royal Infirmary two days before the King's operation and sent down in two large baskets to London with the team so that they would have the advantage of working with their own instruments.

Sir Alexander Fleming Honoured

The freedom of the Borough of Chelsea has been conferred on Sir Alexander Fleming, F.R.S., who has lived there since 1921.

Rosenberg Foundation

Dr. Charles Hill, Secretary of the Association, has been invited by the University of California to lecture for the Rosenberg Foundation of San Francisco on the organization of health, medical, and hospital services. He has had to decline the invitation owing to pressure of work in England, including the presidency of the World Medical Association, which he assumes in October.

National Portrait Gallery

Mr. Geoffrey Langdon Keynes has been reappointed by the Lords Commissioners of the Treasury as a trustee of the National Portrait Gallery for a further term of seven years.

President of Australian Federal Council

Mr. T. E. Victor Hurley has succeeded Sir Henry Newland as resident of the Federal Council of the B.M.A. in Australia.

Faculty of Anaesthetists

The Faculty of Anaesthetists celebrated its first anniversary with a dinner held at the Royal College of Surgeons on March 16. In proposing the health of the College Mr. A. D. Marston, Dean of the Faculty, spoke of his appreciation of the close connexion that now existed between anaesthetists and the Royal College. In reply, Lord Webb-Johnson expressed his delight at the establishment of the Faculty. He pointed out that the anaesthetist was the "clinical physiologist" of the surgical team, and was no longer concerned solely with the supervision of the patient during the operation but was deeply implicated in the pre- and post-operative care of the case. Mr. V. Zachary Cope, toasting the Faculty, commented that it had required no analgesia at its birth and demonstrated that he could express himself in verse with equal ease about anaesthetists as about the acute abdomen. In reply, Dr. Bernard R. M. Johnson, the Vice-Dean, stressed the anaesthetist's concern in the care of the patient before and after his visit to the theatre. Dr. Frankis T. Evans proposed the health of the guests, to which Dr. D. W. Logan, Principal of the University of London, and Sir Cecil Wakeley both replied.

Lecturing in Spain

The British Council is sponsoring a visit to Spain by Professor E. C. Dodds, F.R.S., Courtauld Professor of Biochemistry in the University of London, Director of the Courtauld Institute of Biochemistry (Middlesex Hospital), and editor of the *Journal of Endocrinology*, and Dr. Peter Bishop, consultant to Guy's Hospital, who have been invited by the University of Barcelona to lecture there between March 24 and 30. Professor Dodds's subject is "Theoretical and Practical Aspects of Synthetic Oestrogens," and Dr. Bishop will speak on "Treatment of Functional Menstrual Disorders." These lectures will form part of a month's course on endocrinology arranged by the University of Barcelona Medical Faculty, to which specialists in the subject from several different countries will each contribute a lecture.

Child Welfare

Professor R. W. B. Ellis, of the Department of Child Life and Health, Edinburgh University, and Dr. W. Pearce, of the Scientific Institute for the Study of Delinquency, London, are among those invited by the International Union for Child Welfare to take part in the meeting of the Advisory Committee on Delinquent and Maladjusted Children at the International School of Philosophy, Amersfoort, Holland, on March 28-April 2. The principal subject of discussion will be the training and status of the educational staff in children's and young people's institutions.

Guy's Hospital Dental School

The annual clinical meeting at Guy's Hospital Dental School on March 5 was attended by more than 500 old students. There are at present 350 students in the Dental School at Guy's and many applications for admission have had to be refused. The visitors saw many signs of the rehabilitation of the school since last year, notably the installation of 142 dental chairs of the latest type, a purchase made possible by a university grant. Professor M. Rushton, Nuffield Professor of Dental Medicine, showed some of his work on the structure of teeth. Professor H. R. Fenn demonstrated how polyvinyl chloride could be mixed with appropriate dyes to reproduce clinical material for teaching purposes. Mr. D. J. Anderson showed a method of recording the flow of saliva. Other interesting work on the causation of caries was exhibited in the department of preventive dentistry.

Visit to Greece

Mr. St. John Buxton, the orthopaedic surgeon, and Mr. A. E. Whiffing, technical inspector to the Ministry of Pensions limb-fitting centre at Rochampton, left London for Greece on March 17 for a fortnight's visit sponsored by the British Council and the British Medical Association. Mr. Buxton is lecturing in Athens and Salonika, and his subjects include "Amputation," "Gun-shot Wounds," and "Advances in Orthopaedics (Including Bone Grafting)." Mr. Whiffing, who took with him a crate of artificial British limbs for demonstration purposes, is visiting factories to advise on new methods and appliances. He is accompanying Mr. Buxton on visits to hospitals, including one in the front line.

Hunterian Society

The Hunterian Society's gold medal for 1948 for the best essay by a general practitioner has been awarded to Dr. Jack Lieber for his paper entitled "The Treatment of Obesity in General Practice."

Sheffield Registrars' Group

A United Sheffield Hospitals Registrars' Group was formed on Feb. 4 and has received the official recognition of the United Sheffield Hospitals Medical Committee. The honorary secretary of the group is Dr. R. S. Weetch, Royal Infirmary, Sheffield, 6.

Chinese Award

The President of the National Government of the Republic of China has conferred the Order of the Brilliant Star, with Rosette, upon the Reverend Dr. Arthur Taylor, LL.D., F.R.C.S., in recognition of services rendered during the war.

COMING EVENTS

Physical Society Exhibition

The thirty-third annual exhibition of the Physical Society will be held at the Imperial College of Science and Technology, Prince Consort Road, London, S.W., from April 5 to 8 (both days inclusive).

Tuberculosis Association's Conference

The British Tuberculosis Association's Annual Conference at Cambridge includes the following items in the programme: April 6. *Afternoon*: (1) Dr. J. B. McDougall on "WHO and Tuberculosis"; (2) Dr. R. H. Hazemann, of Paris, on "Tuberculosis in Students and Teachers in France"; (3) Demonstration of tubercle bacilli under the electron microscope in the Cavendish Laboratory. *Evening*: Annual General Meeting. April 7. *Morning*: (1) Mr. Irving Sarol, of New York, on "Resection for Pulmonary Tuberculosis"; (2) Mr.

J. McHale, of Birmingham, on "Post-operative Course of Thoracostomy Cases." *Afternoon*: (3) Dr. J. A. Young, of Cambridge, on "Studies in the Vaccination of Cattle with the Vole Bacillus"; (4) Dr. W. E. Ogden, of Toronto, on "Preclusion of Tuberculous disease by Preclinical Diagnosis and Control: Twenty Years' experience." *April 8. Morning*: (1) Dr. J. M. Lemoine, of Paris, on "Atelectasis"; (2) Dr. Conrad Xalabarder, of Barcelona, on "Atelectasis." *Afternoon*: (3) Mr. John Francis on "Infection with the Bovine Tubercle Bacillus, including its Control and a Comparison of Tuberculosis in Man and Cattle"; (4) Dr. Honor Fell, of Cambridge, on "The Relationship between Cells and Tubercle Bacilli in tissue Culture and *in vivo*," followed by demonstration; (5) Drs. M. Brieger and B. R. Smith on "Observation on the Life History of Tubercle Bacilli"; (6) Drs. V. E. Cosslett and E. M. Brieger—*electron Microscopy Studies of Tubercle Bacilli* (demonstration). *Evening*: Reception and Annual Dinner. April 9. *Morning*: Visit to Papworth. Talk by Dr. R. R. Trail. Golf.

Contraceptive Technique

A lecture and demonstration (on living models) on contraceptive technique will be given by Dr. Marie C. Stopes and Dr. Beddow at the Mothers' Clinic, 108, Whitfield Street, Tottenham Court Road, London, W., on Thursday, April 7, at 2.30 p.m. Tickets must be obtained by letter in advance, as space is limited.

Medical Library Association

The Medical Library Association will hold its 48th Annual Meeting on April 10-14 at Galveston, Texas. The Library of the University of Texas Medical Branch will be the host, and headquarters will be at the Hotel Galvez. Addresses include: "Function of the Historical Collections in Medical Libraries," by Dr. John F. Fulton; "The Elmer Belt Library of Vinciana," by Dr. Elmer Belt; and "Bibliography by Co-operation," by Dr. Luther H. Evans. Particulars may be obtained from the secretary, Medical College of Alabama Medical Library, Birmingham 5, Alabama, U.S.A.

Clinical Medicine

A course of instruction in recent advances in clinical medicine will be held at the Broussais Hospital, 96, Rue Didot, Paris, on May 20-22. The subscription for the course is 2,000 francs. Particulars may be obtained from Professor J. Hamburger, 29, boulevard de Courcelles, Paris, 8c.

Paediatrics Congress

The Sixth International Congress of Paediatrics will be held at Zurich during the last ten days of July, 1950. The congress itself will last four to five days. It is proposed to hold two plenary sessions, each lasting half a day, and a series of simultaneous group sessions, each group session will consist of prearranged lectures lasting from 10 to 30 minutes, followed by open discussion in which no contribution may exceed 5 minutes. Notifications for important lectures not included in the programme can be accepted only through the secretariats of the various national paediatric societies. The manuscripts of lectures (without illustrations) must reach the Organizing Committee not later than April 1, 1950. It is planned to hold a scientific exhibition to display the lecturers' graphs, photographs, etc. The Organizing Committee will provide free of charge the exhibition space and eliotest sheets necessary to hang the graphs. Show-cases for lantern slides, coloured photographs, etc., can be provided only if ordered and paid for well in advance. All those invited to lecture can display their material; other conference members must secure special permission from their national paediatric societies beforehand.

SOCIETIES AND LECTURES

Friday

NORTH OF ENGLAND SOCIETY OF ANAESTHETISTS.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, March 25, 7.30 p.m. "Shock," by Dr. R. P. Harbord.

Monday

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—March 28, 3.45 p.m. "The Knee Joint." Arnold Demonstration by Mr. R. J. Last.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—Jointly with Institute of Urology (University of London), March 28, 5 p.m. "Neurological Disorders of the Urinary Bladder." Urology lecture by Mr. David Band.

WESTMINSTER HOSPITAL SCHOOL OF MEDICINE, Meyerstein Lecture Theatre, Horseferry Road, London, S.W.—March 28, 5.30 p.m. "Stomatitis in Childhood." Clinico-pathological meeting.

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—March 29, 5 p.m. "Histopathology of the Skin," by Dr. I. Muende.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—March 29, 5 p.m. "Cataract Associated with Lesions of the Skin," ophthalmology lecture by Professor A. Franceschetti (Geneva). 6.15 p.m., "Ophthalmic Aspects of Protein Deficiency and Disordered Protein Metabolism," ophthalmology lecture by Professor G. B. Bietti (Pavia).

ROYAL INSTITUTION OF GREAT BRITAIN, 21, Albemarle Street, London, W.—March 29, 5.15 p.m. "Chemistry of the Actinides and Some Newly Discovered Elements," by Professor H. J. Emeléus, D.Sc., F.R.S.

Wednesday

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—March 30, 10 a.m., "The Relationship of Dental Disease to Diseases of the Throat, Nose, and Ear," by Mr. A. C. Deverell. Illustrated by lantern slides.

PHYSICAL SOCIETY: COLOUR GROUP.—At Royal Photographic Society, 16, Prince's Gate, South Kensington, London, S.W., Wednesday, March 30, (1) 3 p.m., 9th annual general meeting of the group. (2) 3.15 p.m., 45th science meeting, "Photoelectric Spectrophotometers and Tricolorimeters." Discussion to be introduced by Dr. T. Vickerstaff.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—March 30, 5 p.m., "Psychosomatic Symptoms in Ophthalmology," ophthalmology lecture by Dr. E. Hartmann (Paris). 6.15 p.m., "Ophthalmic Manifestations of Besnier-Boeck's Disease," ophthalmology lecture by Professor H. J. M. Weve (Rijksuniversiteit).

Thursday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—March 31, 5 p.m. "Pitfalls in Treatment," by Dr. H. Gordon.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At B.M.A. House, Tavistock Square, London, W.C., March 31, 8.30 p.m., "Gynaecology," by Dr. J. H. Sheldon. A discussion will follow.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—March 31, 5 p.m. "Surgical Treatment of the 'Painful Hip Joint.'" Hunterian Lecture by Professor Charles Gray.

Friday

MEDICAL SOCIETY FOR THE CARE OF THE ELDERLY.—At Belmont Road Hospital, Liverpool, April 1, 2 p.m. "Viewpoint on Geriatrics," by Lord Amulree; "Overcoming Physical Limitations," by Dr. Marjory Warren.

SOCIETY OF PUBLIC ANALYSTS: PHYSICAL METHODS GROUP.—At Chemistry Lecture Theatre, The University, Highfields, Nottingham, April 1, 3.30 p.m. 21st Ordinary Meeting. "Electroforetic Analysis." Papers by R. A. Kekwick, D.Sc., Dr. N. H. Martin, A. E. Ambler, B.Sc., Ph.D., and J. Madinaveitia, Ph.D., and A. J. P. Martin, M.A., Ph.D.

Saturday

MEDICAL SOCIETY FOR THE CARE OF THE ELDERLY.—At Belmont Road Hospital, Liverpool, April 2, 9.30 a.m. "Personality Factors in Senile Psychosis," by Dr. J. W. Affleck.

SOUTH WESTERN LARYNGOLOGICAL ASSOCIATION.—At Royal Victoria and West Hants Hospital, Shelley Road, Boscombe, Bournemouth, April 2, 2.30 p.m., clinical meeting.

APPOINTMENTS

The Home Secretary has appointed Mr. Geoffrey Keynes to be a member of the Advisory Committee on the Administration of the Cruelty to Animals Act, 1876, in place of Sir Gordon Gordon-Taylor, who has resigned.

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—Assistant Orthopaedic Surgeon, Norfolk and Norwich Hospital, R. Cornfield Howard, F.R.C.S. Specialist Obstetrician, Peterborough and District Memorial Hospital, Norman Kimbell, M.B., Ch.B., M.R.C.O.G.

FULHAM HOSPITAL, St. Dunstan's Road, Hammersmith, W.—Part-time Senior Registrar to the Ear, Nose, and Throat Department, J. L. Wakelin, M.R.C.S., L.R.C.P., D.L.O. Junior Anaesthetist Registrar, S. Mehlman, M.D.

HALL, HOWARD W., M.B., Ch.B., D.P.H., Deputy Medical Officer of Health and Deputy School Medical Officer for the County Borough of Walsley.

RICE, HUGH MACAN, M.D., Pathologist in Charge, Nottingham General Hospital.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Kelly.—On March 9, 1949, at St. Anne's Nursing Home, Pinner, to Pamela (née Mountain-Palmer), wife of Dr. T. L. Kelly, Eastcote, Middlesex, a son—Nigel.

MacKenzie.—On March 12, 1949, at Shrewsbury, to Marjorie (née Teague) wife of Dr. G. K. MacKenzie, a daughter.

Portch.—On March 1, 1949, at Caythorpe, to Thelma (née Morris, S.R.N.), wife of Dr. G. G. Portch, a son—Christopher John.

DEATHS

Atkinson.—On March 12, 1949, at 202, Abington Avenue, Northampton, Edward William Atkinson, M.R.C.S., L.R.C.P., late of Long Buckby, near Rugby, Northants, aged 67.

Estes.—On March 18, 1949, at Bantlesham, Sandwich, Kent, John Edwin Estes, T.D., M.B., B.Ch., late of Wimbledon, aged 79.

Brown.—On March 13, 1949, at Littlewood, Cranleigh, Daniel Durward Brown, M.D., aged 82.

Bence.—On March 14, 1949, at Woburn, Bedfordshire, Robert Tennant Bence, M.D., aged 76.

Buck.—On March 9, 1949, Arthur Herbert Buck, F.R.C.S., aged 79.

Bokrode.—On March 18, 1949, at Salt Hill House, Chichester, Sussex, Christopher Victor Bokrode, D.S.O., M.D.

Conner.—On March 16, 1949, at All Hallows Vicarage, Greenford, John Richard Tarrant Conner, M.D.

Cooper.—On March 13, 1949, at Stoneleigh, Salcombe, S. Devon, Charles Edward Cooper, M.B., B.Ch.

EPIDEMIOLOGICAL NOTES

Influenza

There were 321 deaths in the great towns in the week ended March 12, compared with 259 in the previous week. Deaths remained practically the same in London and the south-east, but there was a rise in the north, particularly in the north-west, and in the Midlands. The incidence has been high in certain places—for example, Salford, the West Riding of Yorkshire, and Birmingham—but the disease has been of a mild type. From one London borough a report has been received that four patients suffering from influenza developed coffee-ground vomiting and melaena. Nearly all the isolations of virus have been of virus A, but virus B has been found in material received from two school outbreaks and from one fatal case of staphylococcal pneumonia at Leicester.

Registrar-General's Review for 1946

The review issued on March 24 covers the first post-war year. There were 820,719 live births in England and Wales in 1946, which represented a birth rate of 19.2 per 1,000 total population. This was an increase of 3.3 per 1,000 over the rate in the previous year and the highest since 1923, when it was 19.7. Later figures show that the birth rate further increased to 20.5 in 1947 but fell considerably in 1948, the provisional rate for that year, based on the total number registered, being 17.9. There were 53,919 illegitimate births in 1946, a proportion of 6.6% of the total, compared with 9.3% in the previous year. This proportion has since fallen again to 5.3% in 1947. Stillbirths numbered 22,915, representing a rate of 27 per 1,000 live and stillbirths compared with 28 in the previous year, but figures for subsequent years show that by 1948 this rate had fallen to 23.

Of the "legitimate maternities" during the year 44.9% were to mothers with no surviving previous children; 30.2% to mothers with one surviving child; and 12.9% to mothers with two surviving children. There were 10,788 maternities resulting in multiple births, of which 85 were triplets; no quadruplets were born in 1946. Of about 88,000 confinements which took place within 11½ months of marriage some 43,000 occurred within 8½ months of marriage, and of these 36,000 occurred within 7½ months of marriage.

Discussion of Table

In *England and Wales* infectious diseases were less prevalent and there were decreases in the notifications of measles 1,436, whooping-cough 392, acute pneumonia 107, scarlet fever 73, diphtheria 18, dysentery 14, and cerebrospinal fever 13.

A large fall in the notifications of measles was recorded; during the preceding five weeks the weekly number had been doubled. The largest decreases in the incidence of measles during the week were Southampton 324, Staffordshire 284, Devonshire 199, Lancashire 188, Essex 134, Cheshire 118, and Yorkshire West Riding 116; the only large increase was London 250.

Notifications of whooping-cough decreased in most areas, but notably in Lancashire 84. A decrease of 8 in Lancashire was the chief feature of the returns of diphtheria. The fall in the incidence of acute pneumonia was shown mainly in the southern section of the country.

The only large return for dysentery was 24 in Lancashire, where there were 17 notifications fewer than in the preceding week.

In *Scotland* a slight decrease was reported in the incidence of infectious diseases; the falls included acute primary pneumonia 42 and scarlet fever 10. The decline in the incidence of scarlet fever was mainly contributed by the south-eastern area. In the western area a rise of 8 occurred in the notifications of diphtheria.

In *Eire* increases were recorded in the notifications of measles 55, whooping-cough 23, and diarrhoea and enteritis 16. The increased incidence was spread throughout the country, although Dublin C.B. accounted for a large part of it.

In *Northern Ireland* an increase of 69 in the notifications of measles and a decrease of 51 in the notifications of whooping-cough were recorded. The rise in the incidence of measles occurred in the counties of Antrim and Down. A fall in the notifications of whooping-cough was reported throughout the country.

Week Ending March 12

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,178, whooping-cough 2,621, diphtheria 101, measles 17,305, acute pneumonia 1,514, cerebrospinal fever 35, acute poliomyelitis 17, dysentery 49, paratyphoid 3, and typhoid 1.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or return available.

* Measles and whooping-cough are not notifiable in Scotland, and the return are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

"And mind the Hansoms, Horatio"

JOSEPH ALOYSIUS HANSON'S safety-cab was still making a contribution to road safety in the 80's. The automobile was just beginning to splutter its way into history preceded by a man with a red flag. It was in these daring days that Scott's of Edinburgh entered the infant feeding field with M.O.F., but it has changed much since 1887. The same inventiveness and progressive spirit has remained an essential part of Scott's policy. Today, Scott's of Edinburgh provide a whole range of infant foods for mixed-feeding time.

SCOTT'S BABY CEREAL

The ready-cooked baby cereal fortified with essential vitamins and minerals.

SCOTT'S M.O.F.

In use for sixty years. Contains added iron, calcium, phosphorus and vitamin D.

SCOTT'S STRAINED FOODS AND SCOTT'S BABY SOUPS

A tempting variety of fruit, fish, meat and vegetable purees which help to prepare baby's taste-sense for normal food.

SCOTT'S OF EDINBURGH

A. AND R. SCOTT LIMITED,
COLINTON, EDINBURGH

why these two aids
in infant care
receive medical support

In the treatment and care of infants in recent years efforts have been persistent to reduce the incidence of skin irritations such as impetigo and urine rash.

Nothing has contributed more towards meeting this problem than Johnson's Baby Lotion. Wherever it has been used in hospitals, clinics and welfare centres skin conditions improved.

Johnson's Baby Lotion is a homogenized emulsion of specially compounded mineral oil and water with lanolin. It is antiseptic and forms a protective discontinuous film that allows

the normal function of the skin.

Together with Johnson's Baby Powder, here are two indispensable aids in baby care, not only while under your personal supervision but when mothers care for their babies at home.

If you are not yet personally familiar with Johnson's Baby Lotion we will gladly send you samples.

BABY LOTION

For nappie-change to avoid irritations.

BABY POWDER

For after babies' baths.

TREATMENT OF HABITUAL ABORTION

It is quite true that progesterone therapy frequently fails to prevent abortion since there are various other factors which may be responsible. Recent clinical reports, however, indicate that the most common single cause of habitual abortion is progesterone deficiency. In such cases adequate substitutional therapy with 'Proluton' will enable the pregnancy to continue to term.

'PROLUTON'

Injection of Progesterone B.P.

1 c.c. ampoules of 2 mg. 5 mg. and 10 mg.

167/169, GREAT PORTLAND STREET · LONDON, W.

Johnson & Johnson (GT. BRITAIN) LTD. SLOUGH & GARGRAVE

'AVLON'

brand

PETHIDINE HYDROCHLORIDE

Pethidine Hydrochloride possesses analgesic and anti-spasmodic properties, and is used with success in midwifery. It is especially valuable where prolonged labour is due to cervical spasm.

Pethidine Hydrochloride may be employed to alleviate pain in renal, intestinal and biliary colic, in hypersensitive headache, and in neuritis of diverse origin. It may be safely administered in therapeutic doses by the oral and parenteral routes with minimal risks of habituation.

Technical literature and further information will be forwarded on request.

PACKINGS:

Tablets of 0.025 gramme and 0.05 gramme in bottles of 25, 100 and 500.

Ampoules of 0.05 gramme (1 c.c.) in boxes of 10 and 100, and 0.1 gramme (2 c.c.) in boxes of 10 and 100.

Solution in bottles of 25 c.c. (each c.c. containing 0.05 gramme).

Powder: Bottles of 1 gramme.

Pethidine Hydrochloride 100 mg. with 0.216 mg. or 0.432 mg. Hyoscine Hydrobromide

Ampoules of 2 c.c. Boxes of 10 and 100.

Obtainable from your usual suppliers.

IMPERIAL CHEMICAL [PHARMACEUTICALS] LIMITED

(A subsidiary company of Imperial Chemical Industries Limited)

MANCHESTER

Ph.350

A woman with an intimate problem . .

The question of whether or not to use internally worn sanitary protection is one which all women face sooner or later. In doing so, they naturally seek the guidance of one whose advice they completely trust—that of their Doctor. Tampax, which was invented by a gynaecologist and has already been accepted by thousands of members of the Medical Profession throughout the world, deserves your endorsement for its assurance of hygiene, physical comfort and alleviation of mental strain. If you are not acquainted with Tampax, descriptive literature and samples of both absorbency sizes will gladly be sent on request.

★ Tampax may be confidently recommended by Physicians for use by married women during normal menstruation. Its use by unmarried girls should not be advised since the size of the hymenial aperture would cause difficulty in insertion and withdrawal.

. . consults her Doctor

Issued by Tampax Ltd., 110, Jericho Street, London, S.W.1.

CELLON LABORATORIES LTD.

The following tested preparations are available for prompt delivery:—

CELETANE (REGD.) — MEDICATED (LETHANE) HAIR OIL—N.W.F.

The modern insecticide for eradication of head lice (Pediculosis Capitis), as employed by many Medical Officers of Health, etc.

BENZELIA (REGD.)—BENZYL BENZOATE EMULSION—25%

A well-established preparation for rapid eradication of scabies within 48 hours. Also supplied in form of vanishing cream.

OLEOCIDE (REGD.)—OLEO-SULPHONAMIDE

This valuable preparation is a marked advance in Sulphonamide Therapy. Ensures rapid relief of ulcers, Impetigo and other streptococcal infections of the skin; first and second degree burns—broken or unbroken.

CELOZENE (REGD.)—ANTISEPTIC

A powerful non-toxic, non-irritant antiseptic of great value for wounds and cuts, having a Rideal Walker value of 4.0. A special grade can be supplied for sterilising instruments.

SKLEN (REGD.)—PLASTIC BANDAGE REMOVER (NON-INFLAMMABLE)

A solution for dissolving adhesive of plastic bandages enabling easy removal of plaster and subsequent cleansing of adhesive remaining on the skin.

Further information, samples and prices upon request from:

CELLON LABORATORIES LTD.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Heredity and Pulmonary Tuberculosis

Q.—It is said that the genetic factor is mainly responsible for some people's developing clinical pulmonary tuberculosis, whereas the majority do not. How much is known about this, and can you tell me where I can find details?

A.—The writer is not aware of any recent authoritative review of the part played by heredity in determining susceptibility to pulmonary tuberculosis. The evidence that genetic constitution is of importance is based on familial and especially twin studies, on considerations of racial differences, and on laboratory work on animals. Probably the most important single contribution is that of Kallmann and Reisner (*Amer. Rev. Tuberc.*, 1943, 47, 549). Briefly, they found that the chance of developing adult-type pulmonary tuberculosis before the age of 30 in the general population of the State and City of New York was 1.4%. For the various relatives of sufferers the chances were as follows: husbands and wives, 7.1%; half-sibs, 11.9%; parents, 16.9%; full sibs, 25.5%; fraternal co-twins, 25.6%; identical co-twins, 87.3%. This indicates that hereditary constitution is of considerable importance. When the patients were classified in more detail according to the extent and course of the disease, identical twins were actually sixteen times more like each other than fraternal twins. This finding is in harmony with the view that the importance of hereditary constitution lies in the degree of resistance to the established infection rather than in determining whether infection is contracted or not. Observations on man accord well with those on experimental animals, the behaviour of different human populations being paralleled by strains of differing resistance or susceptibility. Thus in Lurie's experiments, in which a low intensity of exposure was used, certain rabbits of high genetic resistance acquired an infection that healed completely, while others, of low genetic resistance, developed fatal tuberculosis.

It is important to realize that the interaction of hereditary and environmental influences must be complex, and the relative importance of heredity will not be the same against different environmental backgrounds. It might not be going too far to suggest that there is no degree of genetic resistance, however high, that could not be overcome by a sufficiently malignant combination of massive infection and adverse environmental conditions; similarly it may be that even those of the greatest genetic susceptibility could be successfully protected under optimum conditions. Kallmann and Reisner's findings apply to conditions as they existed in the nineteen-thirties in the State and City of New York, and the relative importance of hereditary constitution might be very different—either greater or less—in different communities living in different circumstances. It might well be that, in a community living in bad conditions and with a very high incidence of the disease, hereditary constitution would be found to be relatively less important; while in a community enjoying special advantages, and in which the incidence of the disease had been reduced to a very low figure, the influence of heredity would appear to be great; in other words, in such a community those who succumbed in spite of advantageous circumstances would be those who chanced to be genetically strongly predisposed.

Anuria after Sulphonamides

Q.—In domiciliary practice the administration of sulphonamides at intervals of less than 8 hours is difficult, especially during the night. I therefore use sulphamerazine 8-hourly, the last dose being at 10 or 11 p.m. However, I know of two cases of anuria following small doses of this drug, and I feel that this complication is more common with sulphamerazine than with

other sulphonamides. Would using sulphathiazole 4-hourly during the day, substituting sulphamerazine in corresponding dose at 10 p.m. and starting sulphathiazole at 6 a.m. the next morning maintain as effective a concentration of sulphonamide as either drug given separately at the intervals appropriate to itself? Have you any other suggestions for combining minimum toxic effects with adequate blood level of sulphonamide and 8 hours' sleep for the family?

A.—The best method of dealing with the risk of anuria when using sulphonamides is to give a mixture of sulphathiazole, sulphadiazine, and sulphamerazine. The solubility of any one of these does not affect that of the others. It must be given with plenty of fluid and with sodium-citrate in order to keep the urine alkaline. With an alkaline urine there is much less risk of renal symptoms, since the solubility of these substances is greater. If one sulphonamide is to be used alone, sulphathiazole is the least likely to cause toxic symptoms, because it is much more soluble than either sulphadiazine or sulphamerazine, provided the urine is alkaline.

It is clear that an eight-hourly dosage cannot possibly maintain as steady a blood concentration as a four-hourly dosage. Is the question of eight hours' sleep for the family of great importance, in view of the short period for which the sulphonamides are usually given—that is to say, for a maximum of 6 to 8 days?

Hemivertebra

Q.—A boy aged 7 has developed a lateral curve in the lumbar region. X-ray examination demonstrates that he has an extra lumbar half-vertebra. Can you advise me about the treatment of this condition?

A.—The problem of scoliosis is one of the most difficult in orthopaedic surgery, and when the condition is due to congenital hemivertebra the difficulties are even more formidable. Hemivertebra is due to failure of development of one of two lateral centres of ossification of a vertebral body when this is not formed, as it is normally, from a single central ossific centre. It leads to increasing lateral curvature from an early age, and unless treatment is effective the ultimate deformity may be severe. Because the scoliosis is structural in origin, correction is even more difficult than in the ordinary postural scoliosis. For this reason a number of patients have been treated by excision of the hemivertebra. This is a rational method, and though the operation is difficult it is quite practicable in the lumbar region. If excision is deemed inadvisable, treatment will usually follow principles similar to those employed in other varieties of scoliosis. The spine is mobilized as much as possible by a short intensive course of exercises, and, if the deformity is severe or is judged to be increasing, correction is attempted, usually by a divided plaster jacket with a hinge. When maximal correction has been secured an appropriate length of the spine is fused, if necessary in stages, in the hope of maintaining the correction that has been achieved. The most hopeful cases are those in which deformity is of relatively late onset, and in which correction and fusion are consequently not required until the later years of childhood. But when severe deformity is found in early childhood, and particularly if it is increasing, correction and fusion may have to be undertaken without delay. Cases of hemivertebra—apart from those treated by excision—usually fall into this category; and it is unfortunately true that, however intensive and efficient the treatment, the results often leave much to be desired.

Alarming Dreams in the Aged

Q.—Many old people frequently have alarming dreams, such as hanging on to the edge of a precipice, and they wake up in a distressed condition. Is there any known treatment by which the dreams can be prevented or modified? Is it possible that many deaths which occur during sleep may be due to such dreams?

A.—There are some who give a physiological explanation for such dreams, ascribing them to a fall in blood pressure. Possibly this may be the precipitating cause, but obviously the form of the dream—clinging on to a precipice, etc.—cannot be derived from that and demands a psychological explanation.

Dreams are the manifestation during sleep of unsolved problems, many of which are associated with fear. Dreams of falling may be revivals of actual experiences, usually in earliest childhood, when we can do least about it; or they may be symbolic fear of a moral lapse or failure in business or fear of death. Such dreams occur at all times of life, and are not confined to old age, though possibly the lowered inhibition of old age may make them more acute, so that frightening experiences, which occur especially in the helplessness of childhood (including the fear of falling, one of the strongest of primitive fears), emerge into consciousness.

In so far as the fear is psychologically determined, the cure is to get the patient to discover what *latent* fear he may have and face up to it. Otherwise the palliative treatment might be tried of producing deeper sleep by hypnotics; but if this treatment is not successful it sometimes makes the patient worse, since the drugs lessen the inhibition to the repressed fears.

As to the last question on the possibility of nightmares producing death, the general opinion is the other way round. It is now fairly well established that some organic diseases which are not sensed during the day give rise to dreams regarding the affected organ during the night, just as *external* stimuli like an alarm clock may produce a dream. I have had a case in which a patient on two occasions had a dream of being paralysed on the right side, and a few weeks later developed it in fact—not a hysterical but an organic paralysis. Similarly some people have anxiety dreams coming from disease of the heart, and then may die of such disease. Jung has made a special study of this subject, which is also referred to in Freud's *Interpretation of Dreams*.

Marriage of Double First Cousins

Q.—*I have been approached by a young woman for advice on her proposed marriage. Both her own father and her fiancé's are brothers, and the mothers are sisters. As this makes the young couple closer relations than the common first cousins, what are the risks to their children?*

A.—One of the risks inherent in any marriage is that both partners may happen to carry the same harmful recessive gene; any child will then have a 1 in 4 chance of suffering from the condition. This risk is increased in a marriage of blood relatives, who share some of their genes in common. One-eighth of the genes of first cousins are the same, having been received from their common ancestry; in the marriage of double first cousins, as mentioned in the question, the proportion is one-quarter. The consequences may be illustrated by some approximate figures. The chance that any child from a random unrelated marriage will suffer from what is perhaps the commonest serious recessive defect, recessive retinitis pigmentosa, is about 1 in 5,000. The corresponding chance in a marriage of first cousins is about 1 in 1,100, and in a marriage of double first cousins about 1 in 550. To take a much rarer condition—alcaptonuria—the chance of its occurrence in a child from an unrelated marriage is about 1 in 1,000,000, in a first-cousin marriage about 1 in 16,000, and in a double-first-cousin marriage about 1 in 8,000. It will be appreciated, therefore, that the risk of the appearance of some undesirable recessive trait or other is much increased in a marriage of blood relatives. But it is a relative risk; what interests the individual is the absolute risk—that is, the sum of all these chances for all undesirable recessive genes. This is not known, and so it is impossible to say how large the risk may be that in a cousin (or double-cousin) marriage some harmful recessive condition or other may appear. It seems likely, however, that the chance is not large in comparison with all the other risks inherent in pregnancy, childbirth, and early life. For example, it is probably not as great as the risk of haemolytic disease in later-born children in the marriage of an Rh-negative woman to an Rh-positive man. While, then, it must be recognized that the risk is increased, it is probably not of such magnitude that the average sensible person, with a knowledge of the facts, need feel that it outweighs other considerations favouring the marriage. There is one reservation, however. If there is a history of recessively determined abnormality in either family the chance might be relatively large. Scrutiny of the family history would then be necessary, and the proposed marriage might have to be pronounced definitely unwise.

NOTES AND COMMENTS

Chemotherapy of Acute Otitis Media.—Mr. L. F. DAY (Hastings) writes: I did not think that the answer given to the question concerning the very important matter of chemotherapy in acute otitis media ("Any Questions?" March 5, p. 422) was quite in accord with the usual view held by otologists. The answer that I give when asked, as one is asked frequently, is never to give any form of chemotherapy unless there is a free exit for the exudate in the middle-ear cleft or unless myringotomy is imminent. I was sorry to see that the dangers of giving sulphonamides or penicillin in closed infections of the tympanic cavity were not more stressed. To suggest that it is wiser to open the drum if it is red and bulging before giving sulphonamides is putting it very mildly. It is not uncommon to see an extensive necrosis of the mastoid process proceeding under the mask of an adequate dose of one of the sulphonamides, particularly if myringotomy has not been performed. I had such a case recently in which the tympanic membrane was intact, but it was necessary to do a very extensive exenteration of the mastoid cells, exposing the dura mater and lateral sinus widely. This child was 6 years of age and had been on a sulphonamide for two weeks. I have seen children who have been on one of the sulphonamide drugs for ten days who were free from pyrexia and pain but who were severely deaf, with tympanic membranes like wet tissue-paper. The prospect in these cases with regard to the hearing is poor. I know of a few who still show a marked hearing loss six months afterwards. My practice is to make an adequate incision in the tympanic membrane and then to give sulphonamides, or, if the case is a fulminating one, penicillin. Only thus is it possible to ensure a rapid return to normal of the vital structures within the tympanic cavity. I do not believe that the fact that many cases of acute suppurative otitis media may recover, apparently with complete return of the hearing, without myringotomy justifies withholding this simple procedure when the indications for it are present. Apart from the fact that it is the safest course to adopt it gives immediate relief of pain, a shorter convalescence, and a rapid recovery of the hearing loss. There are no complications. With regard to the very early cases, I should say that it would be most unwise to put every child with earache and some injection of the tympanic membrane on a four days' course of chemotherapy. Many of these cases resolve spontaneously in a short time without any interference, before bulging of the drumhead occurs and there are other measures that can be used to hasten recovery. Retained muco-pus in the middle-ear cleft, although the virulence of the organisms may be reduced by drugs, is always liable to organize and form fibrous tissue, causing an adhesive otitis media and permanent deafness. The danger may not be so great in older persons, but in young children it is not possible accurately to assess the hearing, and permanent damage may occur without it becoming apparent for years. There are so many cases to-day of long-standing deafness of obscure origin dating from an early age and it seems not unlikely that there will be very many more in the future if the administration of sulphonamides or penicillin is no combined with daily inspection of the drumhead and careful supervision. With a free discharge of the exudate there can be few more useful purposes to which these drugs can be applied.

Keloid.—Dr. E. JACOBSEN (Kirkby Stephen, Westmorland) writes: In answer to a question regarding the treatment of keloids ("Any Questions?" Feb. 26, p. 377), I should like to mention a more harmless method which is worth-while trying, and which I have used with satisfactory results. It is based on the idea that pepsin has a digestive action on scar tissue. It can be applied either as a compress soaked in a 5% glycerin-pepsin solution, with a piece of oiled silk to keep it moist, or as the following ointment: pepsin 5.0, boric acid 3.0, petroleum jelly to 100.0. Massage with the same ointment is also recommended. The treatment should be continued for several months.

Sir Benjamin Ward Richardson.—Mrs. OLGA SOMECH PHILLIP (4, Perceval Avenue, Belsize Park, N.W.3) writes: I should be grateful if any of your readers could give me personal reminiscences of the late Sir Benjamin Ward Richardson. I should be glad, too, to know of any unpublished writings of his or any letters.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 26 1949

THE SECRETARY REPORTS

THE TRADE UNION CONTROVERSY

Does the Trade Disputes Act of 1906 apply to a medical trade union? Clearly this is an issue of considerable importance, for if it does not so apply there is little case, all other considerations apart, for a medical trade union. After all, the position which the bulk of trade unions enjoy is in large measure due to the protection which this Act affords. Section 3 of the Act provides that an act done by a person in furtherance of a "trade dispute" shall not be actionable on the ground only that it interferes with another person's business, etc.; and Section 4 provides that an action against a trade union, whether of workmen or masters, in respect of any tortious act alleged to have been committed by or on behalf of the trade union shall not be entertained by any court. In short, these sections afford immunity from legal proceedings in respect of certain acts which ordinarily would be actionable wrongs, provided that these acts are committed in furtherance of a trade dispute or committed by or on behalf of a trade union.

The expression "trade dispute" is defined in the Act as meaning a dispute (connected with employment) "between employers and workmen or between workmen and workmen"; and the expression "workmen" is defined as meaning "all persons employed in trade or industry." Now, in the opinion of the counsel consulted by the Association, a medical practitioner is not "employed in trade or industry" and is not a "workman" within the meaning of the Act; and it follows from this view that, unlike a trade union of workmen, a trade union composed of medical practitioners could derive no benefit from Section 3 of the Act. It is to be observed also that Section 4 deals only with "an action against a trade union, whether of workmen or masters." The opinion of counsel is that medical practitioners are neither workmen nor masters within the meaning of the Act, and that Section 4 would not be extended so as to give protection to a medical trade union. "It must be remembered," counsel state, "that the section, in removing from the jurisdiction of the courts in regard to wrongful acts a section of the community, will be read strictly." It appears from this opinion that the widely held opinion that the conversion of the Association into a trade union, or the creation of a trade union (were this practicable) would place it in a peculiarly strong position is without solid foundation so far as it rests on the supposed protection of the Trade Disputes Act, 1906, which offers real advantages to a trade union of "workmen" but not to a trade union of medical practitioners.

It will be seen from these extracts from the Report of the Council on the Constitutional Position of the Association that we are advised that the Act does not apply to a medical trade union. Others have sought legal advice and have been advised that the Act does so apply. To put it in another way, if we accept the high legal opinion we have received, we accept the view that the Act does not apply; if we contemplate the legal opinions which we and others have received, the position is that there is substantial doubt on the point. In either case we cannot confidently assume the protection of the Act. The central issue is one which can only be finally decided in the courts, possibly by the House of Lords.

The constitutional question, which will come before the Special Representative Meeting next week, is but one aspect of the Association's organization. Another, perhaps no less important, is the representative character of the Council, a subject to which the Winchester Division has given its vigorous and stimulating attention. Some proposals on this subject will

be put forward by the Council to the Annual Representative Meeting at Harrogate. Indeed, it is probable that this will be one of the more important questions dealt with at Harrogate in June. Incidentally, members of the Association who have not yet attended an Annual Meeting are warmly invited to make a beginning by attending this year's meeting at Harrogate. The Annual Meeting, whether viewed as a scientific, medico-political, or merely social occasion, is a great affair which members who can spare the time to attend it should not willingly miss.

Terms and Conditions of Service of Specialists

Regional consultants' committees throughout the country are now examining the Ministry's detailed proposals for the terms and conditions of service of specialists published in full in these columns last week. It is interesting to note some lay reactions to the proposals. *The Times*, after a detailed survey of the proposals, made an interesting comment on the position of the general practitioner:

"The lowest rate for the youngest specialist represents roughly the highest rate the really conscientious general practitioner can hope to earn from the Service, if he restricts his practice to 2,500 patients in order to do good work and undertakes a good deal of midwifery and other duties to make up his income. To earn as much as the young specialist he has to work far longer, at greater inconvenience, and with much poorer equipment and services; he has to find and pay his own deputy when absent from work; he has no fixed holidays; he is entitled to no 'distinction awards' or annual increments of pay. Only by undertaking the care of 3,000 or 4,000 patients, which is out of the question for most doctors and intolerable to the best, can he hope to approach the incomes now offered to specialists of more than three or five years' standing. The scale for specialists, like the Spens Report from which it derives, takes no account of the shrewd fear of the earlier Spens Report on general practice that the attractions of medical specialization might turn the ablest doctors away from general practice. Since the Government are committed to a high standard of pay for specialists, a review of the fees of general practitioners is now inevitable. If there is to be a proper balance of remuneration between the different branches of medical work, a substantial proportion of general practitioners, preferably the ablest, will also have to be put into the surtax-paying class."

Levies

There is sometimes confusion between the statutory levy and the voluntary levy, using these terms in relation to the general practitioner service. A statutory levy is a levy imposed on every doctor on the local medical list, and does not require his previous consent. All the executive council requires is a request from the local medical committee backed by a resolution of that committee. A statutory levy can be used only for the expenses of the local medical committee.

A voluntary levy requires the consent of the individual doctor, which must be obtained in the form of a proper legal authorization signed by the doctor himself. The authorization specifies the amount, in respect of each person on the doctor's list, which is to be deducted from the doctor's remuneration from the National Health Service. It is not necessary for the object for which the levy is being collected to be mentioned in the authorization, but such objects must be clearly set out in the covering letter seeking the doctor's signature.

In both cases the proceeds of the levy are passed to the secretary or treasurer of the local medical committee, whose receipt is sufficient for executive council audit purposes.

National Health Service

MORBIDITY STATISTICS

We print below a statement from the Ministry of National Insurance on the collection of data for morbidity statistics.

There are new possibilities in the field of morbidity statistics through the operation of the National Insurance Scheme. These have been considered by the Ministry of National Insurance in collaboration with the Ministry of Health, the Department of Health for Scotland, and the other interested Government departments.

The Ministry of National Insurance has an opportunity to produce for the first time morbidity figures relating to the population insured against sickness and industrial injury by analysing appropriate samples of some 7,000,000 claims for sickness benefit and 750,000 claims for industrial injury benefit which are expected each year. This relates substantially to the whole working population (approaching 25,000,000) but does not, of course, include non-insured groups such as children and old people.

The object is, through the use of appropriate methods of sampling and mechanical tabulation, to produce tables analysing the numbers of persons receiving sickness benefit and industrial injury benefit by such categories as sex, marital status (for women), age group, industry and occupation, geographical locality, nature of incapacitating illness, and duration of incapacity. Where the "exposed to risk" populations can be computed it will be possible to give rates, but there are certain difficulties here until the next census figures are available. Although practical considerations will necessarily impose limitations on what can be done, it is thought that much information can be collected that might well be useful to the cause of preventive medicine. The collection of data, which started on Jan. 1, 1949, will be experimental at first. The results will be subjected to expert scrutiny before any final decision is taken as to publication.

The basis of these statistics is the final medical certificate, and their validity will of course depend upon the diagnostic statements on the certificates. It is appreciated that there will be certain cases where, in the interests of the patient or for some other good reason, the certificate cannot state a precise diagnosis. But, when all allowance is made for such necessary exceptions as these, it is thought that important statistical information can be obtained provided that in the rest of the cases a sufficient degree of precision in diagnosis can be achieved. It is understandable that in the past, when the certificates were given solely to support claims for benefit,

ctors may sometimes have felt that the purpose would be served by a statement which established the patient's incapacity for work but did not aim at the maximum of accuracy in diagnosis. Now, however, that the certificates are to be used also to provide sickness information, the matter is likely to present itself to the medical profession in a different light.

With this in mind, the General Medical Services Committee of the British Medical Association has been consulted by the Ministry of National Insurance. The committee has agreed in principle to the Ministry's proposals and expressed the view that there is now a welcome opportunity to make a start on what is admitted to be a long-felt need.

PROPOSED TERMS FOR HOSPITAL STAFFS SENIOR HOSPITAL MEDICAL OFFICERS

The Ministry of Health states that it appears that some of the phraseology relating to senior hospital medical officers (*Supplement*, March 19, p. 149) has given rise to misunderstandings about the kinds of officers regarded as falling into that group. The following notes may be useful to boards and committees and to regional review committees in clarifying the position.

1. The first group—i.e., those described in paragraph 1 of the proposed terms as "specialists"—is intended to include only those members of medical and dental staffs who are regarded as of full consultant and specialist status, whether

as a result of assessment by a review committee (in the case of existing staff) or of selection by an advisory appointments committee (in the case of future staff appointments).

2. The group described in the proposed terms (paragraph 1 (c)) as "senior hospital medical officers" is intended to include members of medical staffs performing clinical duties, whether of a general or special nature; that is, it includes officers who may be engaged (whether wholly or partly) in a special branch of medicine—e.g., anaesthetists, pathologists, tuberculosis officers, venereologists, psychiatrists, and more rarely physicians, surgeons, or obstetricians—but who individually are not regarded as of full consultant and specialist status. In this sense, therefore, the heading of paragraph 3 of the proposed terms—"other non-specialist grades"—is inaccurate and should be amended by omitting "non-specialist."

APPLICATION OF THE SPENS RECOMMENDATIONS TO MEDICAL TEACHERS AND RESEARCH WORKERS

A Special Committee has been set up by the Council to consider the best method of securing the application of the recommendations of the Spens Committee to medically qualified teachers, research workers, and other practitioners not in contract with, or only partly in contract with, official organs of the National Health Service. The following have already accepted the invitation to serve:

Appointed by Council.—The President, the Chairman of Council Dr. Janet Aitken, Dr. J. Fenton, Dr. S. Cochrane Shanks.

Appointed by the Committee of the Group of Full-time Non-Professorial Medical Teachers, Laboratory and Research Workers.—The Chairman (Dr. R. D. Stuart), Dr. P. D'Arcy Hart, Dr. G. W. Harris, Dr. M. C. G. Israëls, Dr. I. Rannie.

This committee will make recommendations and is empowered to make representations to the appropriate bodies, including the university authorities, the University Grants Committee, the Lord President of the Council, and the Northern Ireland Government in the case of full-time university teachers, and the Medical Research Council, the Agricultural Research Council, the Treasury, the Scientific Civil Service and Government-aided Research Institutes with salary scales based on the Scientific Civil Service in the case of full-time laboratory and research workers, to the Ministry of Health and the Secretary of State for Scotland.

The committee will pay particular attention to the position of the following classes of practitioners:

- (i) full-time university teachers not engaged in hospital work;
- (ii) full-time workers employed by the university and doing clinical hospital work;
- (iii) full-time workers employed by the university and doing non-clinical hospital work;
- (iv) full time non-university research workers.

The recommendations of the Conference of Non-Clinical Medically Qualified Professors, which were accepted by the Non-Professorial Group as a basis for discussion, have been reflected in the Government's initial proposals for the remuneration of clinical specialists engaged in the teaching of medical and dental students.

LOCAL AUTHORITY FEES

A special committee has been set up to negotiate with the associations of local authorities fees not now covered by national agreement. These fees cover the remuneration of police surgeons, medical officers of many types of homes administered by local authorities, fees for certain certificates, etc. The membership of the committee is as follows: J. Fenton (chairman of the Public Health Committee), R. L. Newell (chairman of the Consultants and Specialists Committee), I. D. Grant (chairman of the Private Practice Committee), L. Abel, G. Buchan, A. Dickson Wright, J. A. Gorsky, E. W. Goodwin, R. H. H. Jolly.

WHITLEY MACHINERY IN PUBLIC HEALTH SERVICE

The continued delay in the opening of negotiations on new scales and conditions of service was the first matter to which the Public Health Committee of the Association addressed itself on March 11. The committee unanimously reaffirmed the position which it took in January, and which had been endorsed by the Council, that, negotiations through approved Whitley machinery not having been begun by Feb. 28, advertisements from local authorities be not accepted unless the salaries offered were in conformity with the Association's own proposals for new scales. It was stated that the number of advertisements refused by the *British Medical Journal* since Feb. 28 was eleven. All the medical journals were acting together in this matter.

A copy of a letter sent to town clerks by the Association of Municipal Corporations came before the committee. It was pointed out that one statement in this letter was erroneous—namely, that the question of forming dental and medical functional councils had been in abeyance because, and only because, of the refusal of the professional associations to take part. As the rest of the letter showed quite clearly, the associations of local authorities discovered their own difficulty when they realized that the medical profession was both ready and anxious to begin discussions, bringing into such discussions the Spens Reports.

Discussion took place on the position in Scotland, and the Scottish representatives on the committee all declared that they wished the negotiations to be conducted on a national basis, covering England and Wales and Scotland. They asked, however, that the representation of Scotland on the proposed medical functional council should be increased to three; at present Scotland has one representative out of a total of eleven. The committee agreed to recommend to the Council that the Scottish representation be increased to three.

Equal Pay

A report by Dr. Kelynack, the B.M.A. representative on the Joint Committee on Equal Pay, was laid before the Public Health Committee and was approved. The committee decided to recommend to the Council that steps be taken to widen the representation on the Joint Committee so as to include the nursing profession, certain important teaching bodies, and the medical auxiliaries. The committee further recommended that the Association's support of the Joint Committee's policy of equal pay for equal work in all professions be given on the understanding that any approach to the political parties by the Joint Committee would be on a non-political basis. Dr. Mary Esslemont, on behalf of the Medical Women's Federation, expressed the thanks of that body to the B.M.A. for what it had done in the matter of equal pay. In connexion with a dispute on equal pay in Scotland, it was resolved that the Association's policy be pursued with the utmost vigour.

A cognate question concerned the retirement age of women medical officers. A letter was read from the Medical Women's Federation drawing attention to the fact that nine women medical officers in the education medical service of Glasgow Corporation were subject to a compulsory retiring age of 60, whereas for men medical officers in the same service the age is 65. This provision is embodied in the Corporation's superannuation scheme. In the National Health Service the regulations with regard to retirement are exactly the same for men and for women. The view of the Federation was that there should be no sex differentiation with respect either to retiring age or to option for retirement.

After some discussion the matter was referred to the Scottish Committee for its opinion, and it was suggested that a legal ruling be obtained on the wording of the Glasgow superannuation scheme.

Conflict of Duties

A letter came before the committee addressed by a local authority to a practitioner requesting an indication of his fees for dealing with all cases of sudden illness or accident to officers and employees of the authority, bearing in mind that it would

be necessary for him or someone nominated by him to be continually available. The secretary of the committee had written to the practitioner pointing out that it would be unwise of him to agree to any such arrangement, and that it would be undesirable for the local council to appoint one doctor for emergency cases, as such treatment came within the terms of service of general practitioners under the National Health Service, and any arrangement such as this would cut across the relationship of doctor and patient. The committee endorsed this view.

It was reported that a police authority had decided that the examination of candidates for the force and of officers whose medical fitness had to be determined for the police pensions scheme should in future be carried out by the staff of the medical officer of health. The Deputy Secretary of the Association had written suggesting that the Division which had brought the matter to the attention of Headquarters should protest to the police authority, and if this was without success the matter would be taken up centrally. The policy of the Representative Body is that it should not be part of the duties of the public health staff to examine municipal employees for superannuation, and a similar examination of candidates for the police force would be deprecated. The Public Health Committee endorsed the letter. It was pointed out that the Association had never objected to the appointment of a particular practitioner—e.g., the police surgeon—for such examinations; the issue here was the employment of a whole-time member of the public health staff.

Port Medical Officers

The situation which has arisen at Bristol concerning the duties of port-medical officers was further considered, and the committee decided unanimously to support certain recommendations made by the Occupational Health Committee that no advertisement for medical officers for a National Dock Labour Board be accepted for publication unless a satisfactory assurance was received as to the scope of the work to be undertaken. The committee had previously expressed its opposition to the undertaking of general practice or industrial medicine by whole-time public health medical officers.

From another port it was learned that a medical officer of health was required to attend at 5 a.m. on three mornings a week for the medical examination of aliens arriving by steamer, but that no additional fees were paid at this port (or indeed at other ports outside London) for this service, and that the salary of this particular medical officer of health was only £19 above the minimum. It was agreed to bring pressure to bear upon the local council concerned, and, if that failed, to take up the matter with the Home Office.

Certification of Contacts and Carriers

A protest was made by a local medical committee against a suggestion in E.C.L. 140 that, in a case where it was considered desirable that a carrier or contact should absent himself from work, sickness benefit under the National Insurance Scheme should be paid only on the strength of a certificate by the medical officer of health and not on the strength of a certificate by a general practitioner.

A letter, however, was read from Dr. Massey, chief medical officer of the Ministry of National Insurance, which put a different complexion upon the matter. It was pointed out that the only person who knew the epidemiological situation in the town was the medical officer of health. The general practitioner, while fully aware of the circumstances of his own case, could not know about other cases not within his practice. It was a public health problem which was concerned. The committee, while agreeing with Dr. Massey's argument, thought the original circular was unfortunately worded. It now gathered that there was no question of veto on the general practitioner's certificate by another authority, and it hoped that the position would be clearly explained to those concerned.

The committee considered the Analgesia in Childbirth Bill, but did not think any action on its part was called for. It appointed three of its members to a joint subcommittee which has been set up to consider the report of the Working Committee on Midwives.

PRIVATE PRACTICE COMMITTEE

Fees in Service Cases

A meeting of the Private Practice Committee was held on March 2, with Dr. J. D. Grant presiding. Dr. Robert Forbes was elected deputy chairman of the committee.

A communication was read from the Admiralty stating that the fee payable to Admiralty surgeons and agents for demobilization examinations would be increased to one guinea, subject to an overriding daily maximum, as from Jan. 1 last; also that whatever fees are approved later for vaccination and inoculation would be allowed retrospectively to July 5, 1948. A debatable point on a further communication from the Admiralty concerned fees payable to Admiralty surgeons and agents for visiting a ship alongside the quay and the claim for an increased fee for visiting a ship lying offshore. On the first of these questions the Admiralty was unable to approve such a fee; its decision on the second was still outstanding.

The Air Ministry was unable to agree that the re-examination of R.A.F. personnel for fitness to fly was so comprehensive as to justify the 1½ guineas which the committee had requested. The Ministry pointed out that an R.A.F. medical officer was expected to be able to undertake up to a dozen such examinations in a day if required, and that a civilian practitioner with no previous experience of what was entailed might be expected to complete three such examinations in 2½ hours, for which three guineas would be paid. The chairman said that the form which the practitioner was required to fill in seemed very similar to the ordinary life insurance form, and obviously such examinations called for special care and responsibility. The committee resolved to continue its demand for 1½ guineas.

National Coal Board

It was reported that representations had been made to the National Coal Board on the establishment and remuneration of medical officers in the Board's service. The proposals of a joint subcommittee (with the Occupational Health Committee) were brought forward, which suggested certain ranges for different grades of National Coal Board medical officers. It was pointed out, however, that these figures did not correspond with those demanded for public health medical officers of similar grades, also that increments should be precisely stated. The suggested scales were accepted only provisionally, being subject to revision when the scales for other branches of the profession are determined and subject also to the addition of an exact statement on increments. Dr. John Buchan was elected to the joint subcommittee.

The subcommittee also brought forward other proposals applying to part-time appointments under the Coal Board; these related to methods of remuneration, maximum number of hours per week for part-time appointments, and the question of adequate annual leave.

Allowances to Witnesses

On the question of allowances to medical witnesses in criminal courts, it was stated that the advice which the Home Secretary had given the courts was that, apart from travelling and night allowances, the allowance paid to a professional witness who was a salaried officer and did not lose income by attendance at court should not exceed the allowances payable to an ordinary witness who did not lose income by attendance. Dr. Forbes stated that the Costs in Criminal Cases Act, 1908, on which this instruction was based, did not justify this interpretation. So long as an officer could show that he had had trouble and loss of time in attending and giving evidence he was justified in claiming a special allowance.

It was agreed to send a deputation, consisting of Dr. Forbes, Dr. Gorsky, and Dr. Gregg, to the Home Office on this subject.

The Doctor's Car

The secretary of the committee reported that designs for a badge displaying the letters "B.M.A." had been before the subcommittee appointed on this subject, and the advice of the Automobile Association and the Royal Automobile Club

had been sought. The specimen designs were exhibited and much admired, but objection was taken by some members of the committee to the use of the initials, which it was thought in the minds of some police and other authorities would not immediately connect themselves with doctoring. It was suggested that it be left to the option of a Division or Branch whether in its area this or any other "doctor" sign should be permitted. Eventually, by a vote of 8 to 5, the committee expressed itself as against the use of any sign at all.

The subject of dangerous drugs left in doctors' cars raised another point of interest. The Council had asked that consideration should be given to this subject by the committee. The Home Office had issued a comment on the regulation which came into operation in January requiring drugs to be kept in a locked receptacle which could be opened only by an authorized person. The Secretary of State had been advised that a motor-car or the room of a house could not be regarded as a "receptacle," though a cupboard in a room might properly be so regarded. Some discussion took place on this point. Dr. Gorsky said that there was nothing the committee could do about it. A locked car was not sufficient protection. Another view was that there was no need to lock the car so long as the receptacle itself was locked. It was decided in view of the complications of the situation to seek legal enlightenment on the matter.

Other Business

The committee was informed that further representations had been made to the War Office concerning the question of medical boards for the examination of recruits to the Territorial Army, and that the War Office was willing to receive a deputation on the subject. It was emphasized that a point to be borne in mind was the loss of time entailed in holding medical boards in isolated areas.

It was reported that the Ministry of Pensions was giving consideration to the representations of the committee that the fee payable for a medical report on a deceased soldier, sailor, or airman (Form M.P.W.13) should be increased from 7s. 6d. to 10s. 6d.

The remuneration of civil practitioners for the treatment of service personnel on leave or sick leave, the recently introduced Treasury medical service, fees for medical examinations of candidates for admission to the sea training schools of the Shipping Federation, and the fees for examination of prospective employees in a large business undertaking were among other matters considered. Certain items on the agenda were passed over to the General Medical Services Committee.

GENERAL PRACTICE IN SCOTLAND

Several remits from the recent conference of representatives of Scottish Local Medical Committees were considered by the General Medical Services Subcommittee (Scotland) at B.M.A. House, Edinburgh, on March 10. Dr. W. M. Knox presided. The need for appointing some form of executive committee was debated, and it was decided to appoint a chairman's subcommittee to deal with all matters requiring attention between meetings of the main subcommittee.

It was agreed that all local medical committees should be represented on the General Medical Services Subcommittee (Scotland). The question of weighting of representation was remitted to the chairman's subcommittee for a report. The committee appointed two representatives to discuss with the Consultants and Specialists Committee (Scotland) the problems of general practitioners in hospitals and institutions.

In connexion with a remit urging that travelling expenses and subsistence allowances should be paid from central funds for attendance at local medical committee meetings, it was intimated that at a meeting with representatives of the Department Sir George Henderson had undertaken to inquire further into the question so far as the Highlands and Islands are concerned, and also that the central General Medical Services Committee was considering ways and means of meeting the recognized difficulties of the sparsely populated areas. It was agreed that further information from all the areas of Scotland should be collected.

Similarly, it was reported that as a result of direct negotiation the Department had agreed to take back for further consideration the question of the cost of long-distance telephone calls from rural areas to hospitals, consultants, and laboratories. It was reported that representatives of the Scottish Committee had met the Secretary of State recently to discuss methods of dealing with these and similar difficulties and that local medical committees were to be invited to submit specific proposals for their areas.

It was decided to take up again with the Department the question of free medicines for private patients. The Scottish Secretary drew attention to the information in the *British Medical Journal* that a test case in this matter would shortly be coming before the courts.

The subcommittee decided to accept an invitation issued on behalf of the three Scottish local-authority associations to discuss the question of fees payable to general medical practitioners for services rendered to local authorities. Detailed arrangements were remitted to the chairman's subcommittee, which will discuss with the Department of Health before meeting the local authority associations the subjects mentioned in the invitation in their relationship to the terms of service of practitioners under the National Health Service.

HEALTH SERVICES IN NORTHERN IRELAND

Facts about the progress of the new Health Services in Northern Ireland were given in the Northern Ireland House of Commons this week by Capt. T. O'Neill, Parliamentary Secretary to the Ministry of Health and Local Government. He said that the number of people seeking free dental treatment had greatly exceeded expectations. By January of this year applications had reached 175,000 of which over 100,000 had had treatment completed. While there were grounds for satisfaction here the very considerable outlay in payments to dentists was a matter of some concern. Applications for dental treatment continued at a high level.

The number of prescription forms dispensed by chemists in January last totalled over 370,000 at a cost of approximately £90,000. If maintained at that level, payments in respect of prescriptions dispensed in a full year would exceed £1,000,000.

There had been an avalanche of applications for sight testing and glasses. By Dec. 1, 1948, 120,000 persons had had their sight tested. The cost of supplementary eye services was expected to be £285,000 greater than was originally estimated.

INTERNATIONAL HOLIDAY EXCHANGES

Members are reminded that the Association co-operates in a scheme whereby exchanges can be arranged for British doctors who would like to spend a holiday as guests of Continental doctors, and who would be prepared to offer hospitality in return in this country. The scheme has now been extended to include doctors' unaccompanied children. Any member who would like to send a child to spend a holiday in the household of a Continental doctor, and who is willing to offer hospitality to the child of a Continental doctor in return, is asked to communicate with the Secretary of the Association who will attempt to arrange an exchange. Once again it must be stated that the Association's responsibility in the scheme is limited to arranging the introductions.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils—Fulham, Hackney, Poplar

Non-Corpus Borough Councils—Dartford, WallSEND

Urban District Councils—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tulseley

HEARD AT HEADQUARTERS

The Burden of Work

Widely different accounts are coming from practitioners about the additional burden of work imposed upon them by the new Service. One Midland practitioner with a list of 4,000 and an assistant surprised his colleagues by declaring that, contrary to expectation, neither he nor his assistant had been conscious of any special strain this winter. An industrial practitioner in Yorkshire said that he had been impressed mostly by the restraint and timidity of his patients, who were afraid of taking up unduly the overburdened doctor's time. But there seems to be more said on the other side. There are the people who say, "Here is something for nothing. We must be in on it." There are the hypochondriacs, who are having the time of their lives. And even for the most forbearing lot of patients there is a vast increase of form-filling of all sorts, giving point to the remark of a little girl in a country area in Scotland when she saw the doctor coming, "Oh, mummy, here's the docket man." The Association is collecting material on this matter of burden of work, but obviously it must be spread over a fair period.

Private and Confidential

The Chief Medical Officer of the London County Council, Sir Allen Daley, told an amusing story at a meeting the other night. Medical record-cards of school-children are confidential and not ordinarily to be seen by the parent, but on one occasion by an inadvertence a school nurse handed a youngster his record card, which he took home. By ill luck there had been inserted in the space for the father's occupation the word "tooper," and there was a good deal of trouble before the matter was adjusted. The question of notifications has been a good deal in the air lately. The public accepts without question the notification of infectious and contagious diseases, but whether, as Dr. C. P. Blacker rather optimistically predicted at the Psychological Medicine Group Conference at the B.M.A., it would respond with enthusiasm to the notification of interesting and unusual diseases is another story. Then there has lately been a case in which a Middlesex practitioner refused to divulge to the ambulance service the nature of the illness from which the patient who was to be carried in the ambulance was suffering. The chief officer of the ambulance service stated that this was the first time a doctor had refused such information, which was given without question to hospitals.

Occupational Health Service Bill

It is generally agreed that there should be an extension of the present industrial health services. This has been urged by the B.M.A., the Royal College of Physicians, the Association of Industrial Medical Officers and the Trades Union Congress, but no details, official or unofficial, have so far been published to show how this extension is to come about. A subcommittee of the Occupational Health Committee of the Association is putting forward for discussion an outline of an Occupational Health Services Bill, which should be preceded by a White Paper. This Bill proposes the setting up of a department of occupational health within the Ministry of Health, the department to be under the executive control of a small medical board appointed by the Minister after consultation with the profession. The function of the board would be to institute, supervise and direct on a regional basis a comprehensive occupational health service. There would be regional occupational health consultants.

The Night Duty Doctor

The Woodberry Down Health Centre, of which the Minister of Health laid the foundation stone last week, includes a bedroom for the doctor on night duty, though apparently this arrangement is not rigid and the room could be used for some other purpose. At first sight it seems natural enough that in an institution of this size devoted to medical services, including, in the forefront, general practitioner services, there should be a doctor on the premises at all hours. But the necessity for the night doctor was questioned when the matter was debated at the Royal Society of Medicine, and it was suggested that if a doctor was wanted on a night call it would be equally convenient to telephone him at his home, say a mile away. But

will doctors attached to health centres live no more than a mile away? Will there not be a disposition, when health centres cover the ground, for doctors, in London at any rate, to take their cue from business men who live ten, twenty, thirty miles from their offices? On the basis proposed there will be 150 to 200 health centres in the county of London. Will the doctors attached to them live within five minutes' car distance? If some live near and some afar, the former may complain of an undue burden of night work. A doctor on night duty at the health centre seems reasonable, even though at night there may be no consultations at the centre in the ordinary way.

Pessaries and Dutch Caps

General practitioners may supply pessaries under the National Health Service. As a corollary it was suggested that Dutch caps should be included in the arrangement, but the Ministry cannot agree. Its view is that if a practitioner thinks his patient ought to have such appliances on medical grounds he should refer her to the hospital service. The Executive Subcommittee of the General Medical Services Committee takes exception to this view, and thinks that Dutch caps should be supplied by the practitioner where he considers this to be advisable for medical reasons, and that as part of his terms of service he should ordinarily be expected to undertake any necessary fitting without referring the patient to hospital.

Questions Answered

Private or State Patient

Q.—My executive council informs me that it is not permissible for me to claim an emergency fee or to give a prescription on Form E.C.10 in respect of any patient permanently residing in my area who refuses to register either himself or his family on any doctor's list. One such patient refuses also to pay fees for services rendered by me privately. Am I under any obligation to give medical attention to the family when called?

A.—The General Medical and Pharmaceutical Services Regulations define the categories of persons for whose treatment a practitioner is responsible as follows:

(a) all persons whom he has accepted or agreed to accept for inclusion in his list and who have not been notified to him by the council as having ceased to be on his list;

(b) all persons whom he has accepted or agreed to accept as temporary residents;

(c) all persons who have been assigned to him in accordance with the allocation scheme and who have not been notified to him by the council as having ceased to be on his list;

(d) all persons for whom he may be required under the terms of the allocation scheme to provide treatment pending their acceptance by or assignment to a practitioner or to provide treatment in case of accident or other emergency;

(e) all persons for whose treatment the practitioner is responsible under paragraph 5 of these terms of service (evidence of person's title to obtain treatment).

The case quoted is not covered by any of the above sections and you may treat the patient privately, charging a fee. You are under no obligation to give medical attention to the family when called unless it is specifically claimed under paragraph (d) above.

Prescribing for Expectant Mothers

Q.—Since a number of N.H.S. expectant mothers have come up with demands for prescriptions for cotton-wool and toilet sundries for use by a private maternity home during their lying-in period I referred the matter to the executive council. The council seems nonplussed. What is the position?

A.—A practitioner who has booked an expectant mother may prescribe on Form E.C.10 any drugs and dressings which he considers necessary for the proper care of the patient. Patients who book a midwife may be supplied with a free maternity outfit by the local authority, and the Association has asked the Ministry whether similar arrangements are contemplated when the patient books a general practitioner. Until the Ministry decides the question, it can only be left to the practitioner's discretion what items he prescribes on Form E.C.10,

and, in so far as appliances are concerned, so long as these are included on the Third Schedule of the General Medical and Pharmaceutical Regulations, 1948.

Verbal Report to Coroner

Q.—Is a doctor entitled to the statutory fee of 5s. from a coroner when the latter telephones for a verbal report as opposed to a written report?

A.—There is no statutory fee for a verbal report by a medical practitioner to a coroner. The statutory fees are those for the payment of which provision is made in the Coroners (Amendment) Act, 1926—i.e., in respect of the conduct of a post-mortem examination at the request of a coroner, and for the attendance of a practitioner to give evidence at an inquest. These are the only fees for medical services specifically provided for by the Coroners Acts. However, local authorities are empowered by virtue of Section 25 of the Coroners Act, 1887, to make a schedule of fees, allowances, and disbursements whereby provision can be, and often is, made for the payment of a fee for a written medical report at the request of the coroner.

Correspondence

University Salaries

SIR.—I am very glad to see that the universities are to increase the salaries of teachers in medical schools so that they are less ridiculously different from those of specialists in the National Health Service. It would be interesting, however, to know the logic of the criteria adopted in selecting only teachers in medical schools.

The salary of a professor of physiology in a non-medical school may be £1,450 or £1,500, while that of his colleagues in the medical schools is to be raised to between £2,000 and £2,500. This cannot be because of differences in the standard of the teaching of physiology, for many of the non-medical examinations in physiology exempt students from physiology in the second medical examinations.

Is it because the physiologists in medical schools are medically qualified? But some of them are in fact not so qualified, while many physiologists in non-medical schools are qualified. And what about the first-year subjects? Are teachers of chemistry for the first medical examination to have salaries far higher than teachers for honours degrees in non-medical schools?—I am, etc.,

King's College of Household and Social Science.

JOHN YUDKIN.

Payment by Time

SIR.—The ophthalmic medical practitioners' remuneration is to be reduced—ostensibly because a minority are doing the work in less time than that estimated when the remuneration was agreed. I wish to protest against this principle of payment by time before it is too late. The satisfaction of the parties concerned is the criterion of a task successfully completed, and this bears no relation to the time taken in its performance.

Our organizations should beware of this departmental pitfall before the principle is applied to surgery and, let us say, four cataracts an hour becomes a basis for payment.—I am, etc.,

London, W.1.

H. F. MELHUISH.

Tapering Capitation Fee

SIR.—Much has been written in your correspondence columns about the impossibility of one man properly looking after more than about 2,000 patients in the N.H.S. It may be taken that the writers have practices below this figure. Very little has been said by the "large list" doctors, so that a word from one of them should not be out of place.

In a socialist society there is a tendency in all walks of life to discount the great differences in working capacity which exist between individual members of our species. In the medical sphere these differences are as marked as in any other. Whereas one slow, lazy, or inefficient general practitioner may

find 3,000 patients a burden another quick, efficient man who is fond of his work may manage 5,000 with ease. To do this latter, two requisites are necessary: first, to be a good doctor with a good sense of proportion; second, to be unafraid of hard work. Loud-voiced advocates of practice limitation should mark well and consider these two conditions.

It is true that many doctors cannot or will not look after more than 2,000 people. But to gear down the whole profession to the pace of the slowest is sheer waste of medical man power. Now the fashionable suggestion for a method by which doctors may be prevented from working at full capacity is to impose a sharply tapering capitation fee. This would, of course, make a small practice proportionately more profitable than a large one—and indeed the ostensible object of a tapering capitation fee (hereafter TCF) is to help small practices. To discover whether small practices deserve this help (at the expense of larger ones) it is necessary to consider why some practices are small, and whether a TCF would be justified having regard to each cause of this smallness.

The reasons why practices are small and the bearing of a TCF on each, are

(1) Because the practice has only recently been started. Here the TCF means that established, experienced doctors subsidize young, inexperienced beginners. The two is paid a bigger consultation fee than the tried and trusted veteran. The basic salary alone, for a limited time, is a more suitable form of help in these cases.

(2) Because public opinion considers the doctor to be bad. Here the TCF would subsidize those qualities which the public dislikes.

(3) Because the doctor is either unwilling or unable to work hard. Here the TCF encourages laziness, or subsidizes physical inadequacy.

(4) Because the doctor is a slow worker by nature. Other things being equal, slow work means waste of time. Here the TCF encourages waste of time.

(5) Because the doctor is so meticulously careful that, though the quality of his work is good, his output is small. Ultra-careful methods are excellent in a research worker, but in a GP often denote that he lacks a sense of proportion. (Also see below.)

(6) Because the locality of the practice is so attractive that many doctors settle down there and compete for the limited population. Here the TCF ensures that those doctors practising in pleasant surroundings can have the best of both worlds without sacrificing anything.

(7) Because the local population is sparsely distributed. Here a sufficient mileage and time allowance is what is required. The TCF is of no value in discriminating between concentrated and dispersed practices.

(8) Because the doctor prefers (or has in the past preferred) to treat a few wealthy patients rather than many poor ones. It would be unfair to expect his colleagues (by means of a TCF) to subsidize this doctor's excessive output of bedside manner.

Out of all these causes of smallness there is only one (No. 5) in which a TCF might justifiably operate by increasing the doctor's income so as to be more proportional to his worth. However, the rare cases of this sort could be better met by founding chairs of general medicine or appointing research workers with salaries additional to their capitation fees. From the foregoing considerations it can be seen that a TCF is not justifiable on any general grounds as a means of helping small practices.

To sum up its effects a tapering capitation fee would encourage laziness, slowness, and inefficiency. It would be grossly unfair to those who can and will work hard. By its superior worth of the experienced man would be more than discounted. Anything which discourages people from working is bad and such a device for securing artificial equality of income would seal the ruin of a profession whose traditions of freedom, liberality and steady growth in wisdom are already being ruthlessly trampled underfoot.—I am etc.

J. W. O. HOLMES

British Medical Guild

SIR—May I ask for enlightenment on two matters arising out of the Report of Council (Supplement, Feb. 26, p. 93)?

(1) Has the Association sufficiently considered the implications of the legal maxim *Qui facit per alium facit per se*? (2) Would the British Medical Guild possess any greater powers than the British Medical Association?

The proviso attached to Clause 3 of the Memorandum of Association prohibiting it from acting as a trade union was

no doubt inserted because the Board of Trade required such an assurance that the Association was a union of professional men and women, and not an association of workmen who might be coerced into agreement with the policy of its leaders. Even if the British Medical Guild is sufficiently distinct in law from the Association to enable it to disregard this proviso, might not an injunction still lie against the Association if its Council adopted so crude a device as to call itself by some other name in order to do something which is expressly forbidden by its Memorandum of Association? The Council would surely be regarded as procuring the committal of this illegal act by a mere legal subterfuge. Would not many members regard such conduct as disreputable?

The Report of Council states (*loc. cit.*, end of para. 32, p. 93) that "unless the trustees [of the British Medical Guild] speak with the voice of the medical profession their policy cannot be enforced in any case, and, if they do, then public opinion within the profession will bring back-sliders into line more quickly and effectively than anything else." From this it would appear that the only way in which members of the profession can be induced to follow a particular policy is by peaceful persuasion, based on "public opinion within the profession." Is not the Association already possessed of ample powers for the guidance of such opinion, for its estimation on particular questions (as shown in the recent plebiscites) and for taking whatever steps may be appropriate to bring such opinion before the proper authorities?—I am etc.,

London W1

DONALD C. NORRIS

Cost-of-Living Variation

SIR—During the last few weeks there have been numerous letters in the *British Medical Journal* and numerous resolutions passed at group and committee meetings, all relating to the necessity of a rise in the capitation fee so that the general practitioner should obtain an adequate salary for his manifold services. A survey of these recommendations indicates that they are all based on what can be called a short-term policy. We know that the rural practitioner or the urban practitioner with small lists is finding things financially difficult and attempts are being made to rectify this by an increase in the capitation fee for the first 1,000 patients. This is all to the good, but in addition would it not be wise to consider very seriously the long-term policy?

It has been shown that, with the present population and number of general practitioners each practitioner on the average would have to look after 2,300 patients. In the course of time this distribution may take place. It would enable the doctor to give more time to each patient and perhaps find time for a little leisure and recreation. But the important thing is that his income for these 2,300 patients should be at least equal to that of any dentist or optician—or should approximate to the maximum suggested by the Spens Report. It may necessitate a varying capitation fee for the first 1,000 because of the peculiar circumstances of the rural areas but the 2,000 lists should receive the maximum income.

Some other safeguards must be added. First, the fee for the first 1,000 patients ought to vary annually according to the official Government "index of living", and secondly as the number of general practitioners increases, the average per doctor may decrease. Assuming the same population persists, the maximum salary ought to be earned for the new mean average of patients.—I am etc.

BIRMINGHAM

I. ACKERMAN

Representative Body and Council

SIR—I should like to congratulate Mr. Cyril E. Beare on his letter (Supplement March 5, p. 125). His criticism of Dr. Cockshut's recent articles is just and deserved. They are disingenuous and full of half-truths and evasions. It is one of the greatest weaknesses of the Association that resolutions passed by the R.B. or more frequently permissive riders to resolutions which at the time seem to provide ample safeguards against disaster of one kind or another are disregarded by Council or at least are never heard of again. When the question of reform of our Constitution comes up at the S.R.M. at the end of this month I hope that one of the reforms will be a measure

which will make it obligatory on Council to carry out the expressed wishes and directions of the Representative Body.—I am, etc.,

Wolverhampton.

A. VICTOR RUSSELL.

Position of Assistants

SIR,—The *Supplement* has contained recently an increasing volume of protest on the position of experienced assistants, but I have not yet noted the voice of a principal raised in defence of the now outmoded assistantship system. As the regulations now stand the doctor gaining G.P. experience as an assistant after war service may be exploited to an alarming degree. The advertisement columns of the *Journal* show all too clearly that the trainee assistant with his State-subsidized salary is often better rewarded financially than his more experienced counterpart. Is the B.M.A. too occupied with the question of salaries for the public health medical officers to give some attention to a suitable minimum for assistants?

Almost all recent correspondents have stressed the need for limiting lists to 2,500 patients. I am reluctant to believe that the regulation which allows a principal and one assistant to accept 6,400 patients was originally proposed by the Ministry of Health, which could not fail to be aware of the financial advantage to the employing doctor of this gross overloading. It does look very much like a bargaining clause inserted at the instigation of our negotiating principals.

One has every sympathy for the established doctor in failing health who requires help to run his practice, but for the commercially minded gentleman living well on the proceeds of an inflated list and the labours of an overworked assistant one can but earnestly hope that his days of profiteering are numbered. May I suggest that the B.M.A. give the mere assistant some effective representation and urgently investigate what is to many of us a most grave injustice?—I am, etc.,

FIAT JUSTITIA.

Prescribing for Hospital Out-patients

SIR,—The letter from Miss Margaret E. Brighton, of the National Association of Women Pharmacists (*Supplement*, March 12, p. 143), opens up a point of view which may be irrelevant to her letter but, I think, will have to be dealt with sooner or later. I refer to the necessity for out-patients' being given medicines from hospital at all. The general practitioner with a patient on his or her list is responsible for the treatment of this person, who may be receiving medicines and treatment from a hospital of which the G.P. has no knowledge. When all persons are eligible for free medicines from the G.P. I question the necessity and the wisdom of this custom of hospitals' supplying medicines.

To one accustomed to the habits of private consultants the custom is incomprehensible; no consultant ever prescribed drugs without reporting to the G.P. This immediate report to the G.P., with the necessity of all drugs given to the patient being given with the knowledge, and on the prescription of the G.P., would certainly cut the costs of hospital administration.

Another point arises. I administer penicillin when necessary to patients either in the surgery or in their own houses. Colleagues living in similar towns send their penicillin cases to hospitals. My costs of prescribing for patients will be appreciably higher than theirs, and I am certain to have this matter brought to my notice sooner or later. Also, I am paid the same as they are for my services to my patients, but I do more for mine. There must be some uniformity of practice.—I am, etc.,

Ruthin, Denbighshire.

ENID HUGHES.

Midwives and Doctors

SIR,—At a meeting held at Bristol for the purpose of discussing the Report of the Working Party on Midwives, and addressed by Miss J. P. Ferlie, I was profoundly disturbed to discover the depth of the bitter feeling that exists in the minds of midwives concerning their relationship with the general practitioner under the National Health Service. There appears to be a widespread fear that the domiciliary midwife will be relegated to the position of maternity nurse and general

handywoman, with consequent lowering of the status and dignity of the profession.

The resentment that this fear promulgates in the breasts of the midwives seems to be directed in the main against the general-practitioner obstetrician, who is regarded as being desirous of gathering unto himself the whole of the practice of domiciliary midwifery, normal and otherwise, first by signing the patient on with an E.C.24, secondly by doing the pre-natal examinations himself, and thirdly by exercising his right to deliver the patient irrespective of whether his attendance is obstetrically required or not.

Now let us look at the other side of the picture. The G.P. is somewhat uneasy too. He feels that there is a growing tendency amongst the midwifery hierarchy to regard him as being entirely superfluous to the practice of domiciliary midwifery, that the midwife is to be regarded as the sole practitioner of normal midwifery, and that she should have behind her a team of consultants on whom she can call directly should any abnormality arise. In this arrangement the G.P. will no doubt be cast an occasional pearl in the shape of a torn perineum or a "sticky eye."

During the past 15 years I have engaged extensively in the practice of domiciliary midwifery and enjoyed with the local midwives a professional relationship that has been almost entirely free from friction, and neither side of the partnership has ever bothered to consider whether the midwife has been a "midwife" or a "maternity nurse."

The cessation of this "war" is a matter of extreme urgency if our patients are to receive the comprehensive obstetrical attention we all desire. To this end I put forward the following observations as a possible basis for the solution of the problems that undoubtedly exist.

(1) Normal midwifery should be regarded as the province of the midwife, always bearing in mind that the newly fledged G.P. must himself conduct a considerable number of normal domiciliary cases before he can adequately cope with the abnormal. The midwife must accept the premise that the mere expression of the mother's wish to have a doctor is sufficient reason for one being called.

In this respect one would point out that the presence of the G.P. at the delivery does not necessarily mean that he performs it. In my own case I find it difficult to remember the last time that I conducted a normal delivery in a patient's own home. It has been my habit for years to give an anaesthetic and leave the actual delivery to the midwife or to the pupil if one be present. Even when one applies forceps one's custom is to bring the head down to the perineum and then, whenever possible, to allow the pupil to complete the delivery.

(2) Every mother being confined in her own home must be attended at her delivery by a qualified individual, whether it be G.P. or midwife. There is a tendency among some district sisters to entrust deliveries to pupils, who only send for their superiors if they suspect that some abnormality has arisen. This practice must cease, and qualified midwives who are responsible for the supervision and training of pupils in domiciliary midwifery must themselves be present at every delivery unless prevented by circumstances beyond their control. The natural corollary to this is of course that no district sister shall be responsible for more than one pupil.

(3) Every mother should be given her free choice of doctor and, if possible, her choice of midwife, and both should be engaged at an early stage of pregnancy. The present misguided practice among some midwives and pupils of telling the mothers that they "don't really need a doctor" is to be deprecated.

(4) The pre-natal examinations should normally be carried out by the midwife, and the doctor who is chosen to attend the delivery if required should see the patient at the time of the initial booking and at the 34th and 38th weeks, and at any other time the midwife may desire. These examinations ought to be conducted when both doctor and midwife are present. This could be most conveniently done, in urban areas at least, in existing or future municipal midwifery centres.

(5) At the time of the confinement I suggest the following procedure. The patient is told that as soon as labour commences she must notify the midwife, who then visits the patient and informs the G.P. of the state of the mother. The doctor will then in due course call upon the patient, do whatever examination he considers necessary, and hold himself in readiness to attend the confinement if the midwife requires his help. During the post-natal period the doctor visits the patient as he may desire and carries out the final post-natal examination at about the 6th week as usual.

(6) On the vexed question of the administration of analgesics, I consider that the midwives should be granted authority to use the gas-air machine without the previous consent of a doctor. If the patient is unfit to receive gas-air she should probably have had her

pregnancy terminated months ago. As regards "trilene," I am not happy at present and would for the time being not permit its use without the consent of the doctor. To forbid completely the use of pethidine by a midwife because one member of the profession decided to give it to herself instead of the patient and thereby developed a habit seems about as sensible as closing the Clifton Suspension Bridge to pedestrian traffic because a number of people have chosen to leap therefrom as a quick solution of the problems associated with twentieth-century existence.

The suggestions I have submitted are no doubt imperfect and deserving of considerable criticism, but I do suggest that somewhere along these lines is to be found the solution to the disquiet that now threatens the amicability of the future relationship between the midwife and the general-practitioner obstetrician.—I am, etc.,

Bristol.

O. E. L. SAMPSON.

Breach of Terms of Service

SIR,—Under the above heading you describe (Feb. 26, p. 371) how a Medical Service Committee has recommended that the sum of 150 guineas be withheld from the remuneration of a general practitioner whose offence was the issue of a post-dated medical certificate.

At the hearing there was no legal representation and the procedure does not appear to have been carried out in a manner equivalent to a judicial court of law. It seems reasonable that such a court could, as the practitioner's employer, recommend whether or not his name should be removed from the medical list—i.e., give him the sack—but what is tantamount to imposing a fine, and a heavy one, too, seems to me to be not only a barbarous punishment but one which no non-legal court should have power to recommend. In this case, although regulations are quoted in support of the committee's actions, no such regulation is given to justify the withholding of remuneration, if the summary given by your correspondent is accurate.

At p. 106 of the *Supplement* in the same issue there appears a discussion bearing on this very question. To quote: "The appearance of a solicitor with the defendant often resulted in heavy weather being made of the case . . . and that this magnification might be reflected in the penalty. The view was strongly held that the domestic type of jurisdiction was most suitable. . . ." To my mind magnification of the punishment is impossible in this case. In the next paragraph we read, " . . . in about a year's time the committee would be reviewing procedure. . . ." I urge the General Medical Services Committee of the B.M.A. to act at once and protect doctors from arbitrary treatment of this sort. Doctors must insist that where heavy penalties are involved they are given a fair trial by a properly constituted court. The present position offers an alarming prospect to those who, like myself, have yet to establish themselves in the profession.—I am, etc.,

Sole, Cheshire.

D. C. LINDARS.

* In such cases the Minister of Health may direct that remuneration be withheld under the National Health Service (Service Committees and Tribunal) Regulations, 1948.—Ed., *B.M.J.*

Public Health Salaries

SIR,—Medical members of the Public Health Service must have been cheered by the tone of the leading article under the above title (*Journal*, March 5, p. 401), especially when read in conjunction with the appropriate paragraphs contained in the *Supplement* to the same issue under the heading of "The Secretary Reports." The crux of the matter is that the associations of local authorities have so far refused to open negotiations, knowing full well that in the light of the Spens Reports there must be a substantial increase in the salaries of whole-time medical officers in the Local Government Service, and they fear that increases in the remuneration of their medical staff will mean corresponding increases in the case of other chief officials and their deputies. In general, it is customary for the town clerk to be the highest paid Local Government official, followed by the treasurer and then by other chief officials such as medical officer of health, city engineer, chief education officer, etc.

Is there any reason why the medical officer of health should not, in fact, receive more than the other chief officials?

In this respect it is pertinent to ask, Which of the chief officials has the longest academic training and is required to possess the highest qualifications in the way of degrees and special diplomas? The answer is, without any doubt, the medical officer of health.

Although medical officers of health are heads of departments and thereby chief officials, they are primarily members of the medical profession, and from every point of view it is desirable that remuneration within the Public Health Service should be closely related to that in general practice and the specialist services. Only in this way will the right men be attracted into the Public Health Service. There is already much evidence that young men are not turning towards the Public Health Service as a career. A number of medical schools have ceased to run D.P.H. courses during the last year, and I understand that the candidates attending those courses still running are few in number.

The Public Health Service is an integral part of the National Health Service and must continue to expand. This will not be possible if local health authorities continue with their present outlook, as an example of which I quote a paragraph taken from a recent letter sent by the secretary of the Association of Municipal Corporations to all town clerks:

"If your council should have occasion in the near future to consider the appointment of medical officers in the Public Health Service or School Health Service, I trust that you will not be influenced by the scales of salaries promulgated by the British Medical Association which have not yet been considered by the Association, and if the British Medical Association refuse to accept an advertisement for publication in their journal, there are, of course, many other daily and weekly publications of which your council can avail themselves for this purpose."

I sincerely hope that all members of the Public Health Service will stand firm and will not apply for any black-listed post, and that we shall continue to have the strongest support from the entire medical profession in this matter.—I am, etc.,

M.O.H.

Supplementary Ophthalmic Service

SIR,—A letter has been sent to ophthalmic surgeons informing them that, in spite of energetic protests and the enthusiastic representations of the Negotiating Committee, the Minister has reduced the fee payable to ophthalmic surgeons from £1 11s. 6d. to £1 5s. If the Minister had read the letter of censure which the Ophthalmic Negotiating Committee sent out to ophthalmic surgeons some weeks ago he would have shared my doubts about the enthusiasm of our negotiators, and the protests would probably have been more energetic from a committee composed of ophthalmic surgeons, who were actually working the Supplementary Scheme. The fact that Mr. Bevan values the services of the optician who measures the patient for spectacles at a higher figure than that of an ophthalmic surgeon doing the refraction and making a complete eye examination shows what he thinks of the medical profession in general and of ophthalmic surgeons in particular.—I am, etc.,

Camberley.

LESLIE HARTLEY.

SIR,—It seems incredible after such recent history that the B.M.A. should sponsor an attempt by our Negotiating Committee to take the chestnuts out of the fire for Mr. Bevan, as witness the recent circular letter sent to ophthalmic practitioners (now popularly called O.M.P.s) signed by the chairman of the Ophthalmic Negotiating Subcommittee and the chairman of the Ophthalmic Group Committee. I consider the letter ill-informed and premature, and I for one resent the insinuations and implications, and reject its directions and hope that honest working O.M.P.s will do the same. I have delayed criticism, thinking others might express an opinion; if only a few were forthcoming it should not be assumed that the letter was accepted.

The circular in question starts off by stating that we have been already informed that "your Negotiating Committee" settled terms of service for the Supplementary Ophthalmic Service with the Ministry of Health, and undertook, on their part, that ophthalmic practitioners participating would give a full ophthalmological examination to each case, which they

estimated would occupy an average half-hour, this being apparently the basis of remuneration fixed on the Spens scale. Actually this information was only received a month or six weeks before the circular letter, and at the time of joining the Service nobody knew except by public notice what the payments were to be, let alone any indication of what the forthcoming Service required.

Paragraph 2 says that "the returns of moneys paid by local executive councils out of public funds to the individual ophthalmic practitioners . . . make it clear that this implied contract is not being universally fulfilled; and unfortunately there is a minority of practitioners whose earnings have been such that it must be concluded that they are not maintaining adequate professional standards in their public work."

This is an amazing statement, if only for its loose verbiage and rather comical conclusions. Why "unfortunately"? Why, if it is a fact that a minority of men are earning too much, should it be concluded *ipso facto* that these men are not maintaining adequate public standards in their professional work?

The rest of the paragraph I will develop later, to draw attention quickly to its next phrase. I quote: "The Ophthalmic Group Committee of the B.M.A. have therefore asked the Negotiating Committee to seek a further meeting with the Ministry with a view to modifying the conditions of this service." Here is a very sorry spectacle indeed of our Negotiating Committee begging a meeting with the Ministry to reduce the original working contract. One would imagine that the Ministry should ask our Negotiating Committee for a conference with it. Whose Negotiating Committee are they anyway? Whose interests are they guarding, ours or the Ministry's? It seems to me that the dry rot of May, 1948, is still with us.

The circular ends with the threat, "It would, of course, be easy but distasteful to suggest regulations designed to discipline those who do not so behave." I would warn the writers that the Minister is not the type who takes his orders from anybody's suggestions, and therefore their disciplinary measures might have the opposite effect.

Returning to the first paragraph again, I quote: "Your Negotiating Committee underlook that, on their part, the ophthalmic practitioners participating in this service would give a full ophthalmological examination to each case, which your Committee estimated would occupy on the average half an hour." May I inform our Negotiating Committee that if they meant this the Ministry must have meant something completely different. The form O.S.C.1 signed by G.P.s certifies that the patient needs his eyes tested; the form O.S.C.2 is headed, "Sight testing and supply of glasses." Claim forms are framed, "I have tested the applicant's sight." Not once anywhere in the labyrinth of complicated instructions is there a mention of a complete ophthalmological examination: we are completely ignored. The whole set-up of the Service is an insult to O.M.P.s. How much of the time required to fill up O.S.C.2 forms did our Negotiating Committee allow for out of the half-hour, and if the practitioner makes arrangements for the clerical work to be done might he then have the advantage of allowing himself more time for the actual examination and consequently seeing more patients? Have our Negotiating Committee ever been consulted about the nit-witted form O.C.S.2 with all the elaborate details of the patient, involving four signatures from the doctor, supplemented by his list number twice, etc.?

Of the last hundred patients I have seen at a clinic in South London sixty were between the ages of 55 and 80 and had never had glasses; thirty between the ages of 60 and 75 had had them off the counter, and only ten between 38 and about 56 had been examined by either an O.M.P. or an optician. Inability to buy glasses kept the majority of applicants now applying from having their sight attended to before, and I for one get a great kick out of seeing the joy and hope in the eyes of some of these old people who discover for the first time in 20 or 30 years that they can read again or go to a picture.

After the announcement of the half-hour's examination, imagine the come-down in the second paragraph to a sentence which must be a classic. I quote: "It was never the intention of our Negotiating Committee that refraction work should be paid out of public funds at a rate which could very consider-

ably exceed that which has been generally accepted by the profession as a whole, as being applicable to the 4% of specialists who will participate in the highest Spens award." What a change from complete ophthalmic examination to refraction work! I have an idea that I have seen books on the practice, the art, and the science of refraction, but never one on "refraction work." It can hardly be so derogatory that some people can make money by writing of refraction work, though they may not call it such. Then again, "refraction work," as if the ophthalmic hierarchy never touch it; or do they? Surely they cannot live on trephining all the time and finding bracing climates for relief of post-operative tensions some of the time?

When July 5 came O.M.P.s found a colossus of work. On all sides they were wanted to work the scheme with efficiency and to cope with the avalanche of applicants. Through complete ophthalmological examination on the one hand or sight-testing on the other since July 5 I have spotted and adequately directed for treatment, surgical or otherwise, some interesting cases—one pituitary adenoma, two brain tumours (one frontal and one temporal lobe), two choroidal melanomas, six chronic glaucomas (one with an anterior chamber so big as to belie the diagnosis), numerous retinal and choroidal conditions, hundreds of all manner of lens changes, abnormal corneal conditions, and congenital abnormalities. Add to this nearly 30 domiciliary visits to the aged poor and infirm in London and the Home Counties, out of ordinary working hours, for which I asked no extra fees. Some of these cases required much longer than the "official" half-hour.

Therefore I seriously suggest that, instead of the extraordinary letter of castigation in question, one should be addressed to the men who held the fort, thanking them for saving thousands of patients from being lost to the professional consultant for ever.

Finally, it must be conceded from a democratic no less than a professional point of view that those who negotiate shall have a practical and actual experience of the subject to be negotiated, providing the intricacies of small and big points under discussion with knowledge that experience alone can give. If, added to this, a little grit and determination were also forthcoming to stand up to the Ministry of Health officials and make them see the justice of the professional claims and the service that the O.M.P.s can, and do, render to the public, we then might get somewhere and not once more be betraying ourselves and the public.—I am, etc.,

Walton-on-Thames, Surrey.

JAMES H. MELLOTT.

** Dr. Mellotte asks us to say that this letter was received before the recent reduction in O.M.P.s' fees was announced.—Ed., B.M.J.

SIR,—In reply to Dr. Cecil B. F. Tivy (*Supplement*, March 5, p. 125), my point of view is this. Under existing circumstances an ophthalmic medical practitioner is called on to deal with two distinct classes of patient: (i) those who are referred to him at his own rooms by a G.P. or ophthalmic optician for a medical opinion; (ii) those who come for a routine refraction, mainly under the auspices of the dispensing opticians, and often at clinics organized by them. While I think there is a case for reduction of the fee in regard to the second class of patient, I see none at all in regard to the first. The original guinea-and-a-half fee was only half the usual private consulting fee which those of our representatives who are established in large private practices are accustomed to charge their well-to-do patients. On this basis it is certainly a reasonable fee for a medical ophthalmic examination, irrespective of the time taken.

It is to be hoped that none of our negotiators would be party to excluding the first class of patient from the Supplementary Service, and so degrading it to a level at which it could equally well be run by ophthalmic opticians alone. Such a degradation would clearly not be in the best interests of ophthalmic medical practitioners, G.P.s, ophthalmic opticians, or the public, all of whom stand to benefit if a second opinion is readily available to patients who do not need or do not wish to go to hospital and cannot afford to pay private fees.—I am, etc.,

Birmingham.

J. H. AUSTIN.

Association Notices

FULL-TIME NON-PROFESSORIAL MEDICAL TEACHERS', LABORATORY AND RESEARCH WORKERS' GROUP

The Group Committee invites all members of the Association who are non-professorial medical teachers, laboratory or research workers to join the Non-Professorial Group, which is represented on the new Special Committee which has now been set up by Council (see page 160). Application forms may be obtained from the Secretary, B.M.A. House, or members are invited to approach the representative of the Group Committee in their Region. A list is given below:

Region 1	Dr. I. Rannie (Newcastle).
" 2	Dr. Georgiana Bonser (Leeds).
" 3	Dr. A. R. Kelsall (Sheffield).
" 4	Dr. G. W. Harris (Cambridge).
" 5	Dr. P. D'Arcy Hart (London).
" 6	Dr. J. F. Heggie (London).
" 7	Dr. C. L. Oakley (Bromley).
" 8	Dr. M. R. Pollock (London).
" 9	Dr. A. H. T. Robb-Smith (Oxford).
" 10	Dr. K. E. Cooper (Bristol).
" 11	Dr. F. R. Magarey (Cardiff).
" 12	Mr. B. N. Brooke (Birmingham).
" 13	Dr. M. C. G. Israëls (Manchester).
" 14	Dr. J. C. Brundret (Liverpool).
" 15	Dr. J. W. Howie (Aberdeen).
" 16	Dr. G. R. Tudhope (Dundee).
" 17	Mr. A. G. R. Lowdon (Edinburgh).
" 18	Dr. R. D. Stuart (Glasgow).
" 19	Dr. W. R. M. Morton (Belfast).

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1949. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

Applications for scholarships must be made not later than March 31, 1949, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1949. The value of the prize is approximately £100. The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has been previously published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff of a hospital in Great Britain or N. Ireland and is not

attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1949 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize-winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language, and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope bearing only the motto on the outside.

Essays must be forwarded to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1949. The prize will be awarded at the Annual Meeting of the Association to be held in 1949. Inquiries relative to the prize should be addressed to the Secretary.

PRIZES FOR MEDICAL STUDENTS

The Council of the British Medical Association is prepared to consider the award in 1949 of prizes to medical students for essays submitted in open competition. The subject of the essays for 1949 shall be: "The Value of Observation in the Training of the Medical Student." The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation. No study or essay that has previously been published in the medical press or elsewhere will be considered eligible for a prize.

The following prizes are offered:

National Prizes—six, each of the value of £25.

Regional Prizes—as detailed below, based on the four Regions of the British Medical Students Association:

London Region, 6 prizes (1 of the value of £15; 5 of the value of £7).

Midland Region, 3 prizes (1 of the value of £15; 2 of the value of £7).

Northern Region, 3 prizes (1 of the value of £15; 2 of the value of £7).

Scottish Region, 5 prizes (1 of the value of £15; 4 of the value of £7).

Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for the prizes. The winners of the National Prizes will be ineligible for the award of a Regional Prize. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final. Should the Council of the Association decide that no essay entered is of sufficient merit, no awards shall be made.

Each essay must be typewritten or written legibly in the English language, and must be unsigned and accompanied by a detachable sheet giving the name of the candidate, his medical school, and his B.M.S.A. Region. Essays must be forwarded so as to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1949.

PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the award in 1949 of three prizes each of the value of 20 guineas for the best essay and three prizes each of the value of 10 guineas for the second best essay submitted in open competition by each of the following categories of nurses: (i) Pupil nurses; (ii) State-registered nurses working in a hospital; (iii) State-registered nurses not working in a hospital—i.e., district nurses, private nurses, etc.

The subjects of the essays for 1949 shall be: category (i), "What discipline do you think necessary in the training of nurses?"; category (ii), "What part of nursing duties can be delegated to others with safety?"; category (iii), "The care of old people in their own homes."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes due regard will be given to evidence of personal observation. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Nurses who are undergoing training at a hospital are eligible to compete under category (i); nurses registered by the General Nursing Council are eligible to compete under

categories (ii) and (iii). If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit, no award shall be made. Each essay must be typewritten or legibly written, must be unsigned, and must have attached to it a sealed envelope containing the name and address of the candidate and the category into which he or she falls. Essays must reach the Secretary of the British Medical Association not later than March 31, 1949. Inquiries about the prize should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Diary of Central Meetings

MARCH

- 25 Fri. Venereologists Group Committee, 2.30 p.m.
- 29 Tues. Special Representative Meeting, 10 a.m.
- 30 Wed. Special Representative Meeting, 10 a.m.
- 31 Thurs. Drafting Subcommittee, 2.15 p.m.

APRIL

- 4 Mon. Joint Committee of B.M.A. and National Veterinary Medical Association, 2 p.m.
- 6 Wed. Health Centre Committee, 2 p.m.
- 7 Thurs. Journal Committee, 2 p.m.
- 11 Mon. Armed Forces Committee, 2 p.m.
- 12 Tues. Proprietary Medicines Committee, 11 a.m.
- 12 Tues. Planning Subcommittee, 11 a.m.
- 13 Wed. Charities Committee, 2 p.m.
- 22 Fri. Pathologists Group Committee, 2 p.m.
- 28 Thurs. Occupational Health Committee, 2 p.m.

MAY

- 24 Tues. Scholarships and Grants Subcommittee, 11 a.m.

Branch and Division Meetings to be Held

CAMBERWELL DIVISION.—At St. Giles Hospital, London, S.E., Tuesday, March 29, 8.30 p.m. Mr. D. F. Ellison Nash: "Genito-Urinary Disorders in Childhood." Non-members of the B.M.A. are invited.

LEWISHAM DIVISION.—At Lewisham Hospital, 390, High Street, London, S.E., Friday, April 1, 8.30 p.m. Dr. C. C. Worster-Drought: "Brain Tumours."

MID-ESSEX DIVISION.—At St. John's Hospital, Chelmsford, Sunday, April 3, 10 a.m. Mr. Peter Martin: "Varicose Veins and Vascular Disorders of the Limbs."

NORTH OF ENGLAND BRANCH.—At Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, March 31, 7.15 p.m., Short communications by Mr. Frank Stabler: "What to do until the Arrival of the Flying Squad"; Dr. William Hunter: "The Care of the Perineum During Labour"; Mr. Linton Snaith: "Threatened Abortion." 4.45 p.m., Professor E. Farquhar Murray: "Consideration of the present Position of Midwifery, with some Practical Points"; Mr. H. Harvey Evers: "Comments on the Third Stage of Labour and its Complications."

ROCHDALE DIVISION.—At Rochdale Infirmary, Sunday, March 27, 6 p.m. Agenda: Instruction of Representative to Special Representative Meeting on March 29 and 30, etc.

SALISBURY DIVISION.—At Red Lion Hotel, Salisbury, Wednesday, March 30, 7.30 p.m. for 8 p.m. Annual dinner. Address by Mr. E. Watson-Williams: "Medicine and Magic."

STOCKPORT DIVISION.—At Stockport Masonic Guildhall, Wednesday, March 30, 8.30 p.m. Annual dinner and dance.

WINCHESTER DIVISION.—(1) At Guildhall, Winchester, Thursday, March 31, 3 p.m., Address by Dr. Charles Hill: "Current Problems." Members from adjoining Divisions are invited. (2) At Banqueting Hall, Winchester, Thursday, March 31, 7.30 p.m., Annual dinner dance.

Meetings of Branches and Divisions

MARYLEBONE DIVISION

The following motion has been passed by the Division for inclusion on the agenda for the S.R.M. on March 30:

"That the B.M.A. should protect the public and the profession from the evils inherent in the nationalization of medicine by the exertion of moral force, as it did in January, 1948, and without the formation of any new or parallel organization such as a medical guild."

CITY OF ABERDEEN DIVISION

At a meeting of the Division held on Feb. 15 Professor John Craik, of the Chair of Child Health, Aberdeen University, opened a discussion on "The General Practitioner and the Child Health Service." After giving a short account of the development of the Child Health Service he proceeded to consider how the family doctor

could increase his contribution to child health. He discussed the present relationship of the family doctor to the child-welfare clinics, school clinics, and health visitors, and after reviewing the difficulties in integrating the various services he emphasized the necessity for devising means whereby the family doctor could co-operate and have effective liaison with these services. If group practices and health centres were established it might be possible to attach a health visitor to each practice and to have child-welfare clinics in the health centres. He then considered the most suitable methods of giving graduate and postgraduate instruction on child health, and wondered if it would be possible for a small number of students to be allocated to family doctors for training. Each area should devise its own child health organization rather than accept a centralized and uniform service.

GUILDFORD DIVISION

At a meeting of the Division on Jan. 4 Dr. L. S. Michaeli lectured on "Orthopaedic Treatment in Rheumatic Disease." He said that even the most advanced stages of rheumatoid arthritis and osteoarthritis were accessible to well-considered treatment. The only exceptions were extreme physical or psychological deterioration. Individually designed combinations of exercise, splinting, manipulation, and operation could render bedridden patients capable of walking and sitting, and patients unable to work capable of earning a livelihood. Arthroscopy and lavage (Timbrell Fisher) in the acute phase arthroplasties of elbow and knee, and excision and osteotomy (Batchelor) at the hip were useful operations demanding wider application and further study. He emphasized the difficulties and importance of early accurate diagnosis and of prevention of fixed deformity. Only a complete census would disclose the true extent of neglected invalidism, of wasted man- and woman-power, and of money spent on unproductive maintenance rather than on active rehabilitation. The general practitioner, helped by travelling specialists, should be made a member of the country-wide team undertaking this task and, after suitable training, the continuous follow-up of all patients suffering from severe rheumatism and arthritis.

LINCOLN DIVISION

A General Meeting of the Division, to which all practitioners in the area were invited, was held on Feb. 20, with Dr. A. M. Maiden in the chair.

The chairman opened a discussion on remuneration, and he summarized the report prepared for the consideration of the Conference of Local Medical Committees. He felt it was a good report, and, if it went through, it would be a great help to all practitioners. The most controversial question was the suggestion that the whole of any extra capitation fee be added to the first 1,000 patients on practitioners' lists. Dr. Robertson thought that if all the increase went to the first 1,000 it would benefit the man who restricted his list, and it would be better therefore to base the number on an average list rather than on the first 1,000. Dr. Semple said that one of the objections to the present Service was basic salary, and the present proposal would cut out basic salary and inducement payments, which would be a good thing.

A good deal of attention was given to what action should be taken by the profession if the Minister said that the proposed increase could not be afforded. Dr. Nelson said that he had just come back from South Africa, and there the threat of mass resignation had proved entirely successful. All speakers agreed that this was our best weapon, but professional unity would be very necessary to make it entirely effective.

ST. PANCRA'S DIVISION

The Division was "At Home" to members of neighbouring Divisions in London at B.M.A. House on Feb. 4 for the first showing in this country of a new film entitled "Angina Pectoris," recently purchased by B.M.A. Film Library. Dr. Liston, the chairman of the B.M.A. Film Committee, presided. He said that when the Film Committee published the report of its deliberations two of the most important suggestions which it put forward were (1) that the B.M.A. should encourage the production of appropriate medical films, and (2) that the B.M.A. should set up a medical film library. Such projects would take much time and money, but he announced that they were arranging for the production of a film on "Infection of the Hand and Fingers." They were able to do it through the generosity of one of the leading pharmaceutical houses and without cost to B.M.A. In regard to the Film Library, they had had a most generous gift from Messrs. Kodak, who had presented their medical film library, and those films were now being assessed, as were others received from some of their colleagues—Mr. Dickson Wright, Mr. Lawrence Abel, Mr. Holmes Sellers, and others. The Film Library catalogue would be available on request and without charge to Divisions throughout the country.

The film was then shown. Dr. George E. S. Ward, cardiologist, the Middlesex Hospital, opened the discussion on the film, and, while emphasizing that medical films had their place in medical teaching, he could not exaggerate the importance of not scrapping old methods. After all, the diagnosis of such a condition as angina pectoris very largely depended on the history and clinical signs elicited. He felt that the film was too long, and that parts of it were too detailed and might easily have been omitted as of no real significance. Sir John Parkinson thought that the film had been brilliantly conceived and executed, and that there was very little to criticize. The same view was expressed by Dr. Hope Gosse. Mr. Lawrence Abel put in a plea for an early reference of such cases to the surgeon. A vote of thanks to Dr. Ward and the chairman concluded a most enjoyable and instructive evening.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 2 1949

WHITHER MEDICINE?*

BY

LORD HORDER, G.C.V.O., M.D., F.R.C.P.

Although this Society is not amongst the older-established medical societies of London yet it has, during the 67 years of its existence, attained a high status, following closely the rapid development of the hospital and nurses' training school at Hammersmith. The influence of these medical societies upon the history of our Science and Art is very great, and the contribution made by the West London Society is considerable.

When I was very kindly invited to speak to the Society I was given free choice of subject as between, say, some clinical theme about which I might reasonably convince others, if not myself, that I had had experience, or some aspect of the very topical subject of Medicine in relation to the State. Pressed for a title, I stated it to be "A Guild for Doctors"; and I shall have something to say on that subject. But I have decided to take a larger view of the present situation in our relations with authority, and so I later suggested for my title "Whither Medicine?" The change was influenced somewhat by the knowledge that the Council of the B.M.A. is itself at this moment considering very seriously the desirability of setting up a Guild of doctors which shall be able to impose sanctions which are not free from legal obligations if imposed by the Association itself. Whether such a body will be actually formed, and, if so, of what nature it will be, is for the time being unknown. It is, however, significant that such a step should be definitely contemplated.

In actual fact the profession of Medicine was never a proper Guild in this country. The nearest thing to a Guild was the Barber Surgeons Company, whose history is sufficiently well known to us all. Its natural successors have been the Royal Colleges and the Society of Apothecaries. But the word "guild" has been used symbolically from time to time, as in an address by Osler to the Canadian Medical Society fifty years ago. In that address Osler spoke of four great features of the Guild of Medicine—its noble ancestry, its remarkable solidarity, its progressive character, and its singular beneficence.

A Beneficial Influence

In dilating on the first of these features—the *origins of Medicine*—Osler quotes Gomperz, who pays homage to the Greek School of Medicine because it very early brought the spirit of criticism to bear upon the arbitrary and superstitious views of the phenomena of life that held sway at that time in the world's history. By introducing quiet methodical research into the domain of the physician's

art it exercised a most beneficial influence on the whole intellectual life of mankind.

"The critical sense and sceptical attitude of the Hippocratic School laid the foundations of modern Medicine on broad lines and we owe to it: *first*, the emancipation of medicine from the shackles of priestcraft and of caste; *secondly*, the conception of Medicine as an art based on accurate observation, and as a science, an integral part of the science of man and of nature; *thirdly*, the high moral ideals, expressed in that most memorable of human documents' (Gomperz), the Hippocratic oath; and *fourthly*, the conception and realization of medicine as the profession of a cultivated gentleman. No other profession can boast of the same unbroken continuity of methods and of ideals. We may indeed be justly proud of our apostolic succession. Schools and systems have flourished and gone, schools which have swayed for generations the thought of our guild, and systems that have died before their founders; the philosophies of one age have become the absurdities of the next, and the foolishness of yesterday has become the wisdom of to-morrow; through long ages which were slowly learning what we are hurrying to forget—amid all the changes and chances of twenty-five centuries, the profession has never lacked men who have lived up to these Greek ideals."

Concerning the solidarity of Medicine Osler says:

"Of no other profession is the word universal applicable in the same sense. . . . It is not the prevalence of disease or the existence everywhere of special groups of men to treat it that betokens this solidarity, but it is the identity throughout the civilized world of our ambitions, our methods and our work. To wrest from nature the secrets which have perplexed philosophers in all ages, to track to their sources the causes of disease, to correlate the vast stores of knowledge, that they may be quickly available for the prevention and cure of disease—these are our ambitions. To carefully observe the phenomena of life in all its phases, normal and perverted, to make perfect that most difficult of all arts, the art of observation, to call to aid the science of experimentation, to cultivate the reasoning faculty, so as to be able to know the true from the false—these are our methods. To prevent disease, to relieve suffering and to heal the sick—this is our work. The profession in truth is a sort of guild or brotherhood, any member of which can take up his calling in any part of the world and find brethren whose language and methods and whose aims and ways are identical with his own."

Of the progressive character of Medicine Osler says:

"Based on science, medicine has followed and partaken of its fortunes, so that in the great awakening which has made the nineteenth memorable among centuries, the profession received a quickening impulse more powerful than at any period in its history. With the sole exception of the mechanical sciences, no other department of human knowledge has undergone so profound a change—a change so profound that we who have grown up in it have but slight appreciation of its

* A dinner-address to the West London Medico-Chirurgical Society on Feb. 18.

momentous character. And not only in what has been actually accomplished in unravelling the causes of disease, in perfecting methods of prevention, and in wholesale relief of suffering, but also in the unloading of old formulae and in the substitution of the scientific spirit of free inquiry for cast-iron dogmas we see a promise of still greater achievement and of a more glorious future.

"And lastly, the profession of medicine is distinguished from all others by its *singular beneficence*. It alone does the work of charity in a Jovian and God-like way, dispensing with free hand truly Promethean gifts.

"There are those who listen to me" (continued Osler) "who have seen three of the most benign endowments granted to the race since the great Titan stole fire from the heavens. Search the scriptures of human achievement and you cannot find any to equal in beneficence the introduction of Anaesthesia, Sanitation, with all that it includes, and Asepsis—a short half-century's contribution towards the practical solution of the problems of human suffering, regarded as eternal and insoluble. We form almost a monopoly or trust in this business. Nobody else comes into active competition with us, certainly not the other learned professions which continue along the old lines. Every few years sees some new conquest, so that we have ceased to wonder. The work of half a dozen men, headed by Laveran, has made waste places of the earth habitable and the wilderness to blossom as the rose. . . . There seems to be no limit to the possibilities of scientific medicine, and while philanthropists are turning to it as to the hope of humanity, philosophers see, as in some far-off vision, a science from which may come in the prophetic words of the Son of Sirach, 'Peace over all the earth.'

"Never has the outlook for the profession been brighter. Everywhere the physician is better trained and better equipped than he was twenty-five years ago. Disease is understood more thoroughly, studied more carefully and treated more skilfully. The average sum of human suffering has been reduced in a way to make the angels rejoice. Diseases familiar to our fathers and grandfathers have disappeared, the death rate from others is falling to the vanishing point, and public health measures have lessened the sorrows and brightened the lives of millions. The vagaries and whims, lay and medical, may neither have diminished in number nor lessened in their capacity to distress the faint-hearted who do not appreciate that to the end of time people must imagine vain things, but they are dwarfed by comparison with the colossal advance of the past fifty years."

I make no apology for this long quotation from Osler's address. My reason for introducing it is that I wanted to establish at the outset the basic qualities of the great science and art to which we have sworn allegiance. Because, whether we have taken the actual Hippocratic oath or not—and some of us have—we have surely consecrated ourselves and our lives to Medicine in one or other of its branches. And I could not myself state these basic qualities half so well as they were set forth in the passage I have just quoted.

Straight Ahead!

But if Osler could stake out so splendid a claim for Medicine in 1902, what could he not have done to-day, after nearly fifty more years of breath-taking progress? I remember well, only three years after he gave this Montreal address, he came excitedly into my room straight from Rome, where he had just seen Schaudinn's staggering demonstration of the spirochaete in the lesions of syphilis.

Think what has happened since then. The discovery of radium, the rapid development of x-ray diagnosis and treatment, the recognition of the vitamins, the synthesis of the sex hormones, the introduction of psycho-analysis, the preparation and getting under control of the sulphonamides, of penicillin, and of other antibiotics—this is to name only some of the major additions to the progress of Medicine made during the past half-century, despite two long interrupting world wars.

Very good. A man from Mars, looking on and being ignorant of the queer lapses of the earthly human mind into unintelligence, would think the question that I have taken as the title of this talk to you itself unintelligent! "Whither Medicine?" he would say. "Why, whither else than straight ahead; forging still more weapons with which to conquer disease, taking still more toll of science in the interest of humanity, adding more and more culture to more and more learning, improving both the art and the craft. Medicine has really only just begun its task. It has tackled, and, as you say, not unsuccessfully, the simpler and grosser causes of bodily disablement. You don't die any more in swathes—from smallpox, or plague, or even typhoid fever. Though you don't live longer, more of you live to old age than you used to do. You have got a lot of diseases under control. But I see no decrease as yet in the number who fall victims to what you call high blood-pressure and cardiovascular degeneration. Nor any lessening of the psychoneuroses. Indeed, both of these groups of your patients seem to be increasing in number. And as for the spirit of man, rather than his body, have you even begun to tackle that? Forgive this little criticism," concludes our Martian friend, "but the answer to your question, 'Whither Medicine?' is as I say, 'Straight ahead.'"

And this is surely the answer that every thinking man and woman of us will also give. Why, then, does the question arise? I want to try to answer this further question.

Emergence of the Individual

At this point we have to consider what our American friends are fond of calling "the changing order." On analysis, the salient feature of this "changing order" seems to be the emergence of the individual in Society. This emergence has synchronized with a number of profound alterations in the way of living and in social attitude. Among these are industrial expansion, poverty, the rise of big business and big government, the arrival of social service, and the development of voluntary health insurance plans.

There are two even more basic elements in this concentration upon the individual which is the fundamental feature in the changing order. The first is recognition of the fact that the citizen himself, and not his goods and chattels or the want of them, constitutes the real wealth or poverty of a nation. Thinking men have told us this again and again. (You remember the old cliché: "The health of its citizens is a nation's greatest asset.") But we did not listen until dire national peril was upon us. During the recent war we passed our men and women through a finer comb than we had ever done before, and now, in the post-war era, man-power is the commodity we find in shortest supply.

The second basic element leading to the emergence of the individual is his own spiritual evolution. That the evolution of personality proceeds along lines which tend to help humanity forward is generally accepted. In the course of this advance the individual very reasonably says to Medicine, "What can you do for me?"

The Medical Ideal

Now although it is true that, being based upon Science, Medicine, to be really progressive, should command a degree of autonomy—of freedom—there is agreement that its full powers should be applied to the attainment of the health and happiness of the individual. In so far as the State acts wisely in the interests of the citizen, this desideratum has always been recognized. At first it was recognized only dimly, but later more clearly. There has to-day opened

up for the statesman, the sociologist, and the physician a large field for their inquiry and their action, and this field is common ground. The man of Medicine must not spend all his time in this field; he must go apart, whether in the laboratory or at the bedside, or, like Harvey, walk under the trees rapt in thought so that by observation, by experiment, and by contemplation he may keep Medicine dynamic. For it is *through Medicine* that he makes his contribution, a contribution which no one else can make. To stand aloof from the work going on in this same field is to do a disservice not only to society but to Medicine itself; but to become entirely absorbed in it is to do a disservice no less serious.

Yes, but the contribution that Medicine makes must be fitted into the social structure of the day—"fitted into," work you, not just attached.

As Sigerist puts it, and very aptly:

"The history of the medical ideal is the history of human society. We have seen that the Greek physician was an artisan, that the Roman was a slave to begin with, and the physician of the early middle ages was a cleric, and of the latter part a doctor. The position of the sick in society differed with every cultural epoch. So the demands upon the doctor and his position in the social structure changed constantly. Even the intellectual physician undergoes changes. He deals with advances in science. The physicians whom Melville caricatures so mercilessly in his comedies are also scholars but their actions are grotesque because they abide by outmoded scientific ideals. The 17th century expected quite different treatment from its physicians and had a new medical ideal."

It is the demands made upon the physician by society in the Renaissance, the Baroque period, the enlightenment, the bourgeoisie epochs, are different in detail, but remain the same in their fundamental claims.

"The good physician was at all times the physician who felt himself bound by the medical ideal of his time. Men like Hippocrates, Sydenham, Laennec, Billroth and Osler, were therefore great physicians and will always occupy a special position in the history of medicine, for they came closest to the medical ideal of their time. The clear understanding of the prevailing medical ideal is of great importance."

Can we achieve this end, about which we are agreed? And, if so, how? Let us suppose that we had been given the chance of helping the State by making constructive suggestions—what would these have been? In the first place there is surely consensus concerning certain basic desiderata. Medical services should provide everything that science can offer towards the preservation of health and the cure of disease; the whole corpus of knowledge, as it is termed, must be implemented in the citizen's interest. Then these benefits should be available to the entire population. Seeing that the general public has a vital interest in our plans, it should be adequately represented in their formation. But inasmuch as it is the doctor who must render the medical care, he should play the dominant part in the preparation of the scheme he will be called upon to carry out.

We should have emphasized our belief that gradual extension and improvement of medical care is preferable to revolutionary changes and that, while recognizing Government responsibility for the citizen's health, sweeping legislative action would defeat its own purpose by impairing the spirit and quality of a service which is essentially individual and personal.

Conditions for Fulfilment

As to the conditions necessary to bring about the desiderata I have enumerated, there are certain paramount criteria: the quality of medical care must be preserved; provision of public health services is essential; there must

be effective use of hospitals with adequate facilities; trained professional and non-professional personnel is a *sine qua non*; optimal results require organization and co-ordination of physicians through the extension of medical groups and health centres; voluntary prepayment plans are needed; extensive education for both physicians and the public is required; the local needs of the community must be allowed for; and finally Government help, preferably by grants-in-aid, would be necessary. Indeed, a method of grants-in-aid would seem to offer the brightest promise, so far as help by a central authority is concerned.

We must realize that the practical expressions of unplanned energies are often cumbersome and wasteful. This is the price we pay for highly individualized societies. We began doing things many years ago; we did some of them so well that it has never been considered helpful to scrap them. There are parts of the machinery of our health services which work perfectly; some units stand out as pieces of perfect organization and efficiency—the large teaching hospitals, the well-run cottage hospital, some of our public health services, our Medical Research Council. It is when we come to consider the machine as a whole that organization, and therefore efficiency, are found to be unsatisfactory.

Then, lastly, to make Medicine a complete science in the service of man we must see that it infiltrates the important and now more clearly perceived sphere—as yet largely neglected—of social need. This sphere lies between that in which the diseases of the individual patient are presented to, and treated by, the individual doctor and the sphere in which the preservation of the public health is achieved by the proved methods of the Medical Officer of Health. This largely untitled field includes all the environmental factors which influence the citizen's health and happiness: his conditions of working, his home life, his sense of security or insecurity, and his ignorance of the things that make for the salvation of his body and his mind. In short, as Professor Ryle has stated: "Our next advance (in Medicine) will be . . . concerned with causes, but with the ultimate, rather than the intimate, causes of disease."

Professor Ryle's work at Oxford merits not only recognition but high praise. His term "social pathology" is an apt designation for this work. A study of the environmental factors in the aetiology of disease was overdue; it is high time that they were studied and the results statistically analysed. But when Professor Ryle says that Social Medicine is concerned with the ultimate, rather than with the intimate, cause of disease, I am sure he realizes that he is covering only a part, and not the whole, of a disease process. A disease is the resulting interaction between various extrinsic aetiological factors and the individual patient. It is always the patient that is the main factor. Hence the wisdom of Trousseau's exhortation: *Le malade, toujours le malade*.

Attention to Basic Needs

That, I think, is how we should have put the case for making our contribution to society. But we should have failed in an important part of our duty if we had not, at the same time, warned the State that if it did not attend to the more basic needs of the citizen our direct contribution from Medicine would avail little. By basic needs I mean: a sufficient amount of the proper food, suitable shelter and clothing, a satisfactory job of work, access to fresh air and sun, reasonable leisure, and the amenities of life. The doctor must stake out his claim in every one of these needs, for his is the knowledge that can guide and his is the enthusiasm that can stimulate to achievement. We physicians must lead; we must guide the politicians, since they

cannot act without expert help; we must keep the citizen's end up, since he learns to rely upon us for support.

But suppose the politician won't be guided. Suppose it is as Swift wrote in a letter to Pope: "Although I have known many great Ministers ready enough to hear opinions, yet I have hardly ever seen one that would descend to take Advice; and this pedantry ariseth from a maxim which they themselves do not believe at the time they practise it, that there is something profound in politics, which men of plain honest sense cannot arrive to." In that case the physician has no alternative but to appeal to public opinion, continuing to serve his patient in the manner which he believes to be in the patient's best interest.

Conclusion

That, I say, is how I think we should have stated our case. And so far as we had a chance of so doing, we did. It was a pity that we had no mechanism by which we could express ourselves as a corporate whole. We had no actual Guild. Following a lead by Sir Stewart Duke-Elder, some of us foresaw this plight and urged the formation of an Academy of Medicine, a body which would receive the unquestioned confidence of the Government, the people, and the profession. We failed to get support. So, scattered in different camps, we were taken off our feet. Precipitate action was the order of the day. Action, as Dr. Walshe reminded us in his recent Harveian Oration, is easier than contemplation. Many of us were hustled into this premature action against our better judgment. Almost we became politicians by *force majeure*.

I like to think that were Osler with us to-day he would resist the allurements of the song of the siren of Politics and even, if need be, order his sailors to bind him to the mast of his ship until the danger was past. It is clear to me, from talks I had with him as well as from his published essays, that an attitude of dignity and calm detachment would have characterized this great custodian of Medicine in face of the threat of political pressure.

I have more than once, in my own fashion, preached this gospel. "It is paramount that we remain detached from the general clamour . . . political clamour, the clamour of 'left' and of 'right.' For Medicine there can be no left or right. For Medicine there is only expert knowledge and a rooted adherence to truth. . . . Detachment, public confidence, courage—these are the essentials that enable Medicine to make its contribution to the common Health and Happiness."

One of the finest tributes to the heritage of which we are the trustees was that of Karl Marx: "For thousands of years," he said, "Medicine has united the aims and aspirations of the best and noblest of mankind. To deprecate its treasures is to discount all human endeavour and achievement as naught."

As a humanist I passionately want to see this great heritage placed at the disposal of my fellow men. It is a pity that the present effort of the State to bring this about has so largely failed of its purpose. It might have been a great success. We must still labour to make it so.

The work during 1947 of the Water Pollution Research Laboratory is described in "Water Pollution Research 1947," published for the Department of Scientific and Industrial Research by H.M.S.O. (price 1s. 6d., by post 1s. 8d.). The report of the Board deals chiefly with the results obtained in some of the investigations made. The report of the Director of Research gives a more complete survey of the work on the treatment of water, sewage, and industrial effluents, and on the effects of pollution of natural waters. An appendix gives references to papers published during the year in scientific journals describing some of the investigations in detail.

VENOUS THROMBOSIS AND ANTICOAGULANTS

BY

K. P. BALL, M.D., M.R.C.P.

Chief Assistant, Medical Department, Central Middlesex Hospital

AND

H. O. HUGHES, O.B.E., M.R.C.S., L.R.C.P.

Resident Pathologist, Central Middlesex Hospital

Venous thrombosis and pulmonary embolism are common occurrences in all branches of medical practice, and are conditions which cause prolonged disability or sudden death. In recent years both pathologists and clinicians have demonstrated that the usual site of origin of venous thrombosis is the deep veins of the calf. It has also been shown that venous thrombosis can be prevented, and that when it does occur effective treatment can be given.

This paper deals with 100 consecutive patients requiring anticoagulant treatment. They have been drawn from 11 of the 23 wards of the hospital over a period of 20 months. Its purpose is to indicate the frequency of venous thrombosis, to discuss its early clinical features, and to show that anticoagulants are an effective method of treatment.

Incidence

Venous thrombosis and pulmonary embolism occur more often in medical patients than is generally realized. In a series of necropsies on cases of pulmonary embolism Hampton and Castleman (1940) found that 60% were in medical patients and that one-half of these had suffered from heart disease.

Bauer (1946) found that, out of 804 cases of thrombosis from ten of the largest Swedish hospitals in the year 1935 56% came from medical wards. In the present series 42.5% of the cases of thrombo-embolism were medical, 35% were obstetric, and 22.5% were surgical. The distribution of the 85 cases of venous thrombosis and pulmonary embolism, and of the 15 cases treated prophylactically, was as follows:

Aetiology of 100 Cases Treated with Anticoagulants

Treated cases of thrombo-embolism (85):

Medical (36):	
Cardiovascular (cardiac infarction, 9; heart failure, 4; angina pectoris, 1; old apoplexy, 3)	17
Previous leg thrombosis	4
Pneumonia	3
Carcinoma	2
Axillary vein thrombosis	2
Other conditions	8
Surgical (19):	
Gynaecological (hysterectomy, 5)	7
Appendicectomy	3
Herniorrhaphy	2
Other operations	7
Obstetric (30):	
Normal delivery	9
Forcible delivery	5
Caesarean section	3
Other abnormalities of childbirth, toxæmia, post-partum hæmorrhage, etc.	7
Abortion	5
Pregnancy	1
Prophylactic treatment (15):	
Myocardial infarction	7
Developing thrombosis	5
History of previous thrombosis	3

Development of Venous Thrombosis

Most textbooks state that pulmonary emboli are secondary to thrombosis in the pelvic or femoral veins, upholding the view put forward by Virchow a hundred years ago. However, a number of workers have shown that in nearly all cases of venous thrombosis the process, although often spreading to the femoral veins, begins in the deep veins of the calf. From a series of necropsies Frykholm (1946)

concluded that the four areas of origin of venous thrombosis are: the plantar veins, the veins of the musculature of the calf, the branches of the deep femoral vein in the adductor musculature, and the visceral pelvic veins, and that of these the calf was the most frequent site.

By using phlebography Bauer (1946) has shown that venous thrombosis almost always arises in the deep veins of the lower leg, and only in about 3% of the cases in the thigh or the pelvis. He suggests that from its origin in a calf vein the thrombus spreads in the direction of the blood stream up into the femoral vein, becoming a slippery "eel-like formation, 40-50 cm. long." As venous obstruction is still only slight, the clinical signs at this stage are few, yet the patient is in great danger of the thrombus becoming detached and causing a fatal pulmonary embolism. It is probable that only a freshly formed thrombus breaks off, so that if the clotting process can be halted organization on to the vein wall will occur.

Clinical Features

Unless doctors and nurses become more "thrombosis-minded" venous thrombosis will too often remain undiagnosed until it has spread to the femoral vein and produced an obvious swelling of the leg or sudden death through pulmonary embolism has occurred. The key to effective treatment is early diagnosis while the process is limited to the calf.

Leg Thrombosis.—The patient may complain of a slight pain or cramp in the calf. Although rarely severe, it may have disturbed his night's rest. On examination there may be some swelling of the affected leg, which should be confirmed by measurement. The superficial veins may be more engorged than on the normal side. Palpation must be performed carefully, and it is best done with the patient lying with the knees half flexed and the soles of the feet placed flat on the mattress, the calf muscles thus being relaxed. Firm palpation, beginning in the popliteal fossa and working downwards, reveals a tender area, the site of the thrombosis. Local induration of the calf muscles is often felt. The plantar, femoral, and adductor regions should also be examined for local tenderness. Finally the knee is extended and the foot dorsiflexed. In the presence of deep calf thrombosis a pain in the calf is felt (Homan's sign). Quite apart from the local signs, however, the presence of an unexplained fever or tachycardia in any patient confined to bed should suggest the possibility of venous thrombosis and should lead to a thorough examination of the legs.

Pulmonary Embolism.—In a patient who develops a sudden pain in the chest with haemoptysis, and who also has venous thrombosis of one leg, the diagnosis is relatively simple. In medical patients, however, the primary heart or chest disease often obscures the true condition, and the diagnosis may be made only post mortem. Sudden onset of pleural pain is one of the commonest symptoms, but the pain may be central and mimic coronary thrombosis. Where shock, tachycardia, and cyanosis are also present the similarity may be very great. Fever, pleurisy, haemoptysis, and signs of consolidation may suggest a diagnosis of pneumonia. Sagall, Bornstein, and Wolff (1945) analysed 108 cases of pulmonary embolism and found that the clinical picture had simulated pneumonia, angina pectoris, myocardial infarction, pleurisy, vascular collapse, or acute heart failure in a large number of cases. Thus, unless the possibility of a pulmonary embolism is always considered when the above signs are present, the diagnosis may be made too late. The warning of the first attack not being heeded, a fatal embolism occurs before effective treatment is given.

In the present series leg thrombosis occurred in 74 patients, and the clinical site of origin was: deep calf veins only, 39; calf and femoral veins, 18; calf, femoral, and iliac veins, 15; and femoral veins only, 2. Of the 35 cases in which the femoral vein was involved, calf thrombosis was also present in 33. In the two cases in which femoral thrombosis alone occurred, one followed ligation of the

great saphenous vein with retrograde injection, and the other case was probably secondary to thrombosis in the adductor muscles.

Plantar tenderness probably indicates thrombosis of the plantar veins, and was present in six out of 43 cases examined for it. The left leg alone was affected in 38 cases, the right alone in 31, and both together in 5.

Pulmonary embolism occurred 29 times in 27 patients. In 13 cases it was the presenting sign and in eight a complication of leg thrombosis before the start of treatment. Pulmonary embolism occurred after treatment had been started in eight cases; it will be referred to later. In 19 of the 27 patients the leg was the source of the embolism. In the other eight cases no definite source was discovered.

End-results of Venous Thrombosis

When the dangers of pulmonary embolism have passed, the patient who has suffered occlusion of the deep leg veins as a result of thrombosis faces further trouble in the years ahead. Bauer (1946) followed up 100 patients who had had deep leg thrombosis more than 10 years previously. Of these, 91 had developed indurative lesions of the leg, and in 79 ulcers had appeared. Birger (1947) found that 40% of 869 cases of leg ulcer were caused by a previous deep thrombosis.

Too often do we forget the connexion between the young mother with her puerperal thrombosis and the older woman, crippled with leg ulcers, who frequents the "varicose vein" clinic. Her legs are a perpetual source of grievance to her. She cannot do a full day's work, and her bandaged legs destroy all her social confidence. The amount of misery and time lost from work on account of these conditions is undoubtedly very great. According to Roholm (1937), in the year 1936 the sequelae of venous thrombosis cost Denmark, with a population of 3½ million inhabitants, 2 million crowns (approximately £100,000) in the value of lost working days, hospital expenses, etc.

Treatment

Prevention.—(a) *Active exercises* performed in bed and early post-operative walking considerably reduce the incidence of venous thrombosis. The dangers of venous stagnation in medical patients are probably even greater than in the surgical, particularly where there is a predominance of older patients and those suffering from heart disease. Old, ill, and obese patients often lie with their legs still for hours on end, providing ideal conditions for the development of thrombosis. Active leg exercises should become a routine for such patients. At each ward round the doctor should encourage them to "go for a walk in bed" at frequent intervals. In order to get the co-operation of the nursing staff, a full explanation of the need for preventing thrombosis should be given to them. They should know the clinical features of early thrombosis and should be instructed to notify the doctor immediately on finding them. Active leg exercises will not become effective unless the doctors, nurses, and patients are continually mindful of them, so that they become part of the ward routine. (b) *Anticoagulants*:—Both heparin and dicoumarol have been used to prevent thrombosis, but in this hospital their use has been limited to post-operative or puerperal patients giving a history of previous thrombosis, and to cases of coronary thrombosis, a disease in which thrombo-embolic complications often occur.

Curative.—Until about ten years ago deep thrombosis was always treated by prolonged immobilization of the affected leg. Unfortunately it is still a common practice, and is even advocated in several recently published textbooks. During the past few years, however, three new

methods have been tried—venous ligation, lumbar sympathetic block, and the use of anticoagulants. Each method has its supporters, and each has helped to reduce the dangers of venous thrombosis. Compared with venous ligation, the anticoagulants have the advantage of preventing the spread of thrombosis wherever its site of origin, and this may be obscure. On the other hand, they do not immediately stop emboli from occurring. Femoral venous ligation immediately prevents further emboli from arising distal to the ligation, but it does not stop thrombosis developing elsewhere, and in a few cases permanent swelling of the leg results. Lumbar sympathetic block has been used successfully to overcome peripheral vascular spasm, both venous and arterial, which accompanies the fully developed whiteleg, and in such cases, combined with anticoagulants, it is probably the treatment of choice. This treatment should rarely be necessary, since early treatment with anticoagulants can prevent the spread of thrombosis from calf to thigh, and the resultant whiteleg.

Heparin and Dicoumarol

These are the only anticoagulants in common use, and their respective advantages and disadvantages may be tabulated as follows:

Heparin

Difficult to administer
Expensive (£2-£4 daily)
Immediate effect
Few contraindications
Haemorrhages rare
Effect disappears in three hours
Coagulation times are simple to perform, and not essential

Dicoumarol

Easy to administer
Cheap
Effect delayed 24-72 hours
Many contraindications
Haemorrhages frequent
Effect disappears in 3-10 days
Prothrombin content estimations imperative, and require expert technicians

Indications for Anticoagulants.—(1) Deep venous thrombosis; (2) pulmonary embolism; (3) arterial embolism (with or without surgery); (4) coronary thrombosis, especially with recurrent attacks.

Contraindications to Dicoumarol.—Liver damage, renal failure, recent operations on the brain or spinal cord, subacute bacterial endocarditis, and of course disease with bleeding tendencies have all been considered contraindications to the use of dicoumarol. With normal precautions it can be safely used in the puerperium.

Method of Administration

Although the anticoagulant effect of heparin is more satisfactory than that of dicoumarol, the difficulty of prolonged intravenous administration, together with its expense, is against its routine use. In the present series the drugs have been used together, heparin being given until dicoumarol has taken effect. In most cases heparin has been given by continuous drip for 48-72 hours at a rate of 1,500 to 2,000 international units per hour. If after a few hours the coagulation time by the Lee and White method has not increased two to three times (normal 3-8 minutes in our experience) the dose is increased. In cases of pulmonary embolism an immediate initial dose of 10,000 i.u. is given. Alternatively, heparin may be given by intermittent intravenous injections of 10,000 i.u. four- to six-hourly, especially where intravenous fluids are contraindicated, as in congestive heart failure.*

Dicoumarol, 300 mg., is given when the heparin is started, and 200 mg. on the second day. The subsequent doses are regulated by daily estimations of the plasma prothrombin content (P.C.). It is important that no further dicoumarol be given until the result of estimating the P.C. has been obtained. Patients vary considerably in their sensitivity to the drug, and if the dose is not controlled by daily

P.C. estimations a serious haemorrhage may occur. Blood for P.C. estimation should not be taken until three hours after the last dose of heparin has been given. The aim of treatment is to keep the P.C. between 10 and 30% of normal (Allen *et al.*, 1947). If the P.C. exceeds 10% a serious haemorrhage is rare, and so long as it is kept below 30% a spread of the thrombosis is unlikely to occur. Dicoumarol is given in the afternoon, the dose depending on the P.C. taken the same day. If the P.C. exceeds 20%, 200 mg. usually given, although when the P.C. is rapidly falling 100 mg. is sufficient. It must be remembered that a single dose of dicoumarol does not exert its full effect for from 24 to 48 hours. Moreover, in one patient the first two doses may cause an adequate fall of P.C. for a week while in another a daily dose of 200 mg. may be necessary for several days. The daily dose for most cases is about 100 mg., but it is quite impossible to generalize. The keeping of a simple chart showing the dose of dicoumarol (one-half of the page and the P.C. on the other makes easier to assess the effect of treatment. The accompanying diagram illustrates the effect of treatment in a patient

Chart showing the effect of treatment in a case of deep thrombosis occurring after a cardiac infarction.

who developed a deep calf thrombosis after a cardiac infarction. Patients with a high fever or debilitating diseases appear to be more sensitive to the drug and should be treated with greater caution.

Treatment should be continued until the patient is fit to be ambulant, a therapeutic depression of the P.C. for 7 days usually being adequate. As the anticoagulant effect may last for several days after stopping the drug, care should be taken to see that the P.C. has returned to normal before the patient is discharged. Confidence in the P.C. estimation is essential for dicoumarol therapy. In the earlier cases of the series dosage was controlled by Witts and Hopson's (1940) modification of Fullerton's (1940) method of prothrombin estimation performed on alternate days. Further experience has shown that this method is unsatisfactory as is explained later.

Leg movements are not restricted, and after the first 48 hours they are actively encouraged. The patient is usually allowed up within three to four days of starting treatment. A Dickson Wright elastic bandage is applied if there is any residual oedema, although women usually prefer an elastic stocking.

Toxic Reaction

Haemorrhage is always a danger during treatment with dicoumarol, although accurate daily estimations of the prothrombin content, together with careful daily examination of the patient for evidence of minor bleeding, will reduce serious haemorrhage to a minimum. Among the 93 patients treated with dicoumarol some form of haemorrhage

* The needle described by Olousson (*Lancet*, 1948, 2, 495) facilitates intermittent injections.

occurred in 26 (28%). In only 8 (8.6%) cases was it considered of moderate or severe degree, and four of these were among the first 10 of the 93 cases treated. The higher incidence of haemorrhage in the earlier cases was almost certainly due to the lack of daily prothrombin estimations and to the use of "stypven" as thromboplastin for the estimations performed. Familiarity with dicoumarol has certainly not bred contempt, but rather an increasing respect for its dangers. In 18 cases slight haemorrhage occurred. In eight of these, however, the only sign was the return of red lochia in the puerperium. This was a frequent event in the treatment of puerperal thrombosis, but was never more than slight in amount and never caused any anxiety.

In the present cases epistaxis (8), vaginal haemorrhage (1), and from the puerperium (4), ecchymoses (4), haematuria (1), haematoma (2), wound bleeding (2), and oral bleeding (1) all occurred. There was no death from dicoumarol haemorrhage.

Dicoumarol is stopped immediately haemorrhage occurs, and in the mild cases no further action is necessary. If the bleeding is serious, however, one or more pints of fresh blood and an intravenous injection of 100–300 mg. of vitamin K ("synkavit") are given. The latter should be administered slowly, since it may cause giddiness and flushing. Earlier reports stated that vitamin K did not affect dicoumarol haemorrhage, but the doses given were certainly too small. In large doses the P.C. usually rises considerably within two days, but, as with dicoumarol itself, there is a lag in its effect, and fresh blood must be given where an immediate source of prothrombin is required. Haemorrhage may even continue after the P.C. has returned to normal, though this has never been serious.

The incidence of haemorrhage was certainly greater than in some other reported series. Allen *et al.* (1947) had an incidence of 5.2% amongst 1,983 post-operative cases treated prophylactically, and Bruzelius (1945) noted 9.7% of haemorrhages amongst 113 cases. With the present method of P.C. estimation the incidence of severe haemorrhage should be reduced to a minimum.

Heparin rarely produced side-effects. Minor haemorrhages (5), pyrexia probably due to the heparin (4), and pain in the loin following injection (1) all occurred, but only in the last case had treatment to be stopped.

Results

Heparin and dicoumarol were used together in 76 cases, dicoumarol alone in 17, and heparin alone in 7. Heparin was given by continuous intravenous drip in 48 cases, intermittently in 21, and in the remainder by a combination of these methods.

The assessment of results in a small and varied series is difficult and may be misleading. Most cases of leg thrombosis rapidly improved after treatment, the pain and tenderness diminished, and the temperature became normal within four to five days.

In five of the 74 cases of deep thrombosis treated a relapse or spread to the opposite side took place while under treatment, although in two of them there was inadequate depression of the prothrombin content. Relapse of the thrombosis also occurred in four cases after treatment had been stopped. This result compared favourably with that of conservative treatment, in which there is a spread to the opposite leg in 31% of cases (Zilliacus, 1946).

Pulmonary embolism usually responds well to treatment. There were 29 instances of pulmonary embolism in 27 cases: 21 were treated after the attack had taken place, (two of these patients died, both with congestive heart failure following a recent cardiac infarction); in five pulmonary embolism occurred during the treatment, none of them

proving fatal; and in three it took place after treatment had been stopped, one of these being fatal. In the last-mentioned case the patient, a woman aged 37, was admitted in severe shock with an extensive thrombophlebitis of the leg associated with superficial haemorrhagic bullae. Dicoumarol was not given, owing to anuria, and she was treated with continuous intravenous heparin. She died from massive pulmonary embolism 43 hours after treatment had been stopped because of increasing haemorrhagic bullae.

Of the 30 treated obstetric cases, 19 were confined in this hospital. These 19 can be compared with 16 cases of puerperal deep thrombosis treated conservatively here during the previous four years. Although the two series are not entirely comparable, the very striking difference in the length of stay in hospital and in the time spent in bed on account of the thrombosis is undoubtedly of significance. The stay in hospital has fallen from 68 to 24 days, and the time in bed from 45 to 6 days. In the group treated conservatively there were four cases of pulmonary embolism (one fatal). In the group treated with anticoagulants there was one non-fatal case of pulmonary embolism.

To summarize, no fatal case of pulmonary embolism occurred among 74 cases of deep leg thrombosis during treatment. And as a result of treatment in cases of puerperal thrombosis the time spent in bed has been reduced from six weeks to one week.

Discussion and Conclusions

Early diagnosis is the key to effective treatment. The irregular post-operative temperature, the "cramp" in the calf, the "stitch in the chest"—all frequent warning signs—are too rarely heeded. A realization of the significance of these signs could prevent many cases of massive pulmonary embolism, and could relieve the patient with extending calf thrombosis from a future of ulcerated legs.

Many other workers agree with the conclusion derived from the present study, that the anticoagulants provide an effective method of treatment of venous thrombosis. Allen and his associates (1947) treated 352 cases of post-operative venous thrombosis. Venous thrombosis or pulmonary embolism later appeared in only nine cases, although from previous experience at the Mayo Clinic 88 cases would have been expected if conservative treatment had been adopted. No cases of fatal embolism occurred, although 20 would have been expected. Bauer (1946) found that the recumbent period due to leg thrombosis had been reduced from 40 days in 264 cases with conservative treatment to 4.7 days in 209 cases using heparin. Zilliacus (1946) reported similar results.

The sheet-anchor of dicoumarol treatment is an accurate method of estimating the prothrombin content. Unless the physician is fully confident in the results he is obtaining he should use heparin and not dicoumarol. As we consider this a matter of fundamental importance, full details of the method of prothrombin content estimation are given. We have heard of a number of cases of serious or fatal dicoumarol haemorrhage occurring with inadequate control, and as a consequence the drug has been regarded by some as too dangerous to use. We believe that it is the control and not the drug which is at fault.

Venous thrombosis is still frequently treated by immobilization. When the anticoagulants are used they are often given too late, in adequate doses, or without proper supervision. As effective treatment requires some experience, it is suggested that every hospital should have an anticoagulant service under the control of a physician who would be responsible for all cases of venous thrombosis arising. The occasional use of these drugs by each member

of the staff cannot lead to the best results. Although the majority of cases seen will be those occurring while the patient is in hospital under treatment for some other condition, the development of deep venous thrombosis at home should be considered an indication for urgent admission. Anticoagulants can only rarely be given at home, owing to the difficulties of administering heparin and controlling dicoumarol, although intermittent injections of heparin should be used in any emergency until the patient can be transferred to hospital.

The ideal anticoagulant would be one that is easy to administer, is inexpensive, and has a widely separated therapeutic and toxic dose. Both the present drugs fall short of this ideal. Suitable slow-acting preparations of heparin for subcutaneous injection may overcome some of the difficulties in future. In the meanwhile we have found the above method to be effective and safe. Present difficulties of administering anticoagulants are no excuse for withholding a valuable and often life-saving treatment.

Summary

An analysis of 100 patients treated with anticoagulants is given. Venous thrombosis is found to be a common condition, especially in medical patients. Heparin combined with dicoumarol is an effective method of treatment. Since dicoumarol needs careful control, a reliable technique for estimating the plasma prothrombin content is described. With early diagnosis of leg thrombosis, both pulmonary embolism and chronic leg ulcers can be prevented.

Our thanks are due to all those members of the hospital staff who allowed us to treat their patients, to the nursing staff whose co-operation has made this study possible, and to Dr. H. Lempert and Dr. G. Discombe for their help and suggestions concerning prothrombin estimation.

APPENDIX

Technique for Estimating Prothrombin Content of Plasma

In the earlier cases of this study the Witts-Fullerton technique for the estimation of prothrombin index was used. In this procedure the thromboplastin is a mixture of Russell-viper venom and lecithin. It was soon found that the prothrombin indices obtained in this way were an insensitive and unreliable control of the clinical state of the patient. A comparison with Quick's (1938) method was therefore made, and, in agreement with Wilson (1947) and Lempert (1948—personal communication), it was found that quantitative values of prothrombin content determined by Quick's method, using human brain as a source of thromboplastin, were a reliable and delicate index of the clinical haemorrhagic tendency of the patient.

Success, however, with Quick's method depends on minute attention to detail, detection of any deterioration of reagent or fault in technique by reference to a control, and previous and expected results on the test plasma. In other words, the approach to this test must be similar to the approach to the routine Wassermann reaction. The literature offers only the outline of the procedure, and so the full details, with an indication of common difficulties, are given here.

Glassware and saline solutions must be prepared as for the Wassermann test.

Reagents

1. *Stock Thromboplastin Powder*.—A coronal slice 2 in. (5 cm.) thick is taken from a human cerebral hemisphere which shows no sign of local disease and has been removed within 24 hours of death, and the blood vessels and pia are removed under a gentle stream of tap-water. With scissors, the slice is cut into cubes of about 1 cm., which are allowed to fall into 450 ml. of acetone contained in a 12-in. (30-cm.) mortar. The fragments are then ground up with a pestle, and after about five minutes the acetone is decanted and replaced by fresh acetone, the grinding being repeated. This procedure is repeated five or six times, when one is left with a mealy mass. The last sample of acetone is decanted; the residue is squeezed between large sheets of blotting-paper, then spread out on a fresh sheet of blotting-paper and placed in a

37°-C. incubator for not more than 15 minutes. It is then ground up again for two to three minutes and spread out on large sheets of filter-paper in a vacuum desiccator over anhydrous calcium chloride. The desiccator is attached to a motor-driven vacuum pump (Hyvac or Pulsometer Geryk) and evacuated continuously until a constant minimum pressure is obtained (usually one to two hours). The dry product is ground in the mortar and passed through a nest of metal filters (B.S.S. No. 41 mesh 10, 25, and 44). The product is a cream-coloured sand-like dust which is stored *in vacuo* over calcium chloride at 4° C. It remains active for at least four months.

2. *Working Thromboplastin Solution*.—Weigh out approximately 0.65 g. of stock powder and pour into a universal container, adding 9.5 ml. of saline. Mix thoroughly. Incubate in a 50°-C. incubator or bath for 12 minutes, shake the container three or four times during this period. Cool immediately in running tap-water. Centrifuge at 1,000–1,500 r.p.m. for two minutes to bring down coarse particles. Pipette off milky supernatant fluid and store at 4° C. The solution thus stored remains active for 48 hours and is prepared on alternate days. A satisfactory reagent is one which gives times for normal control of 15 to 18 seconds, undiluted plasma being used, and figures of the order of 20, 25, 32, and 59 seconds for the 50, 30, 20, and 10% dilutions in saline of the control plasma. Storage for 24 hours appears to enhance the activity of the solution.

3. *0.2% Calcium Chloride*.—Dissolve 2 g. of pure anhydrous calcium chloride in 1,000 ml. of distilled water. Filter.

4. *M/10 Potassium Oxalate*.—Dissolve 1.84 g. of anhydrous potassium oxalate in 100 ml. of distilled water.

Procedure

A tube containing the calcium chloride reagent is first placed in the 37°-C. bath and allowed to reach this temperature. 0.1 ml. of thromboplastin solution is added to 0.1 ml. of plasma or diluted plasma in a 3 by $\frac{1}{4}$ in. (7.5 by 1.25 cm.) tube, which is placed in a 37°-C. water-bath. Then 0.1 ml. of calcium chloride solution at 37° C. is rapidly added, a spring-loaded syringe pipette with teat being used, thus mixing the compounds. At the moment when the calcium chloride is added a stop-watch started.

The tube is shaken gently in the water-bath for three to five seconds, then removed and tilted almost horizontally so that the contents run back and forth at eye level. The end-point is the appearance of a fibrin clot, and the time is then taken.

A control plasma is tested daily in parallel with the unknown because reference to a standard curve made up for a batch of dried brain is not satisfactory. It is best to use plasma taken daily from a single volunteer; a new volunteer is obtained each week, usually one of the medical or laboratory staff. The control plasma is tested undiluted and diluted with saline to contain 50, 30, 20, and 10% plasma. A new calibration curve is therefore set up for each day's observations. The patient plasma is tested undiluted and the prothrombin content read from the curve. All estimations are set up in duplicate and the mean taken.

Special Points

1. *Collection of Plasma*.—Exactly 0.5 ml. of oxalate solution is placed in a bijou bottle and 4.5 ml. of blood obtained by venipuncture is added. The contents are mixed and the bottle then centrifuged, the supernatant plasma being removed and stored at 4° C., at which temperature it will keep for four to six hours. It is convenient to arrange for blood samples to be collected about 10 a.m. (thus avoiding excessive lipaemia) and to perform all the day's tests together at some convenient time.

2. *Normal controls and their dilutions* do give somewhat varying times with any batch of "thromboplastin solution" but at the critical dilutions—namely, 30, 20, and 10%—this is practically insignificant, as the spread is such that it does not permit one to deduce from the plot of a single control the prothrombin content of an unknown sample at these critical levels to within $\pm 5\%$.

3. *Reading of "End-points"*.—This requires practice. Undiluted controls and normal plasmas appear to clot solidly, the dilutions of the control and test plasmas with lower prothrombin the end-point takes the form of very fine white flakes or fibres which develop fairly sharply.

4. *Clotting* is accelerated when thromboplastin and plasma are incubated together for more than four minutes before the addition of calcium chloride; it is essential to place no more thromboplastin-plasma mixtures in the water-bath than can be comfortably treated with calcium chloride and read within this time.

DIABETIC COMA

TREATMENT WITH AND WITHOUT THE EARLY
ADMINISTRATION OF GLUCOSE

BY

J. LEE, M.B., M.R.C.P.

D. NAIDOO, B.Sc., M.R.C.P.Ed., D.C.H.

AND

J. A. TORRENS, M.D., F.R.C.P.

(From a Medical Unit, West Middlesex Hospital)

Whether or not glucose should be administered in the treatment of diabetic coma has been the subject of much discussion. On the one hand, Himsworth (1932) states that the "essential therapeutic agent in the treatment of diabetic intoxication is glucose, and unless this substance is present in sufficient amounts insulin is relatively impotent." He claims that the "maximum of sugar and the minimum of insulin" should be given, and "not conversely as is the present practice."

On the other hand, Root (1945a) holds that the harmful effects of glucose may be concealed in the early case of coma by the insulin simultaneously administered. He claims that the moderate case may be converted into a severe one requiring excessive insulin dosage, and that "in advanced coma glucose administration either by mouth or by needle may cause anuria and death."

Among those who administer glucose as a beneficial procedure are Bertram (1932), Lawrence (1936), and Soskin (1945). Joslin (1947) and Root (1945a) are the leading opponents of glucose administration, but they do give carbohydrate in quantities not exceeding 10 g. per hour during the second to sixth hour of treatment.

Physiological evidence supporting the administration of glucose is based largely on experimental work such as that of Soskin and Levine (1937, 1944), and of Mirsky *et al.* (1937). The last-named authors have shown that intravenous injection of large amounts of glucose (a) to anaesthetized nephrectomized depancreatized dogs, (b) to anaesthetized depancreatized dogs, and (c) to phlorhizinized depancreatized dogs, where insulin was entirely excluded, resulted in the disappearance of ketone bodies. The antiketogenic action of glucose is attributed to the deposition of glycogen in the liver and a consequent cessation of ketone formation. Soskin and Levine's (1937) depancreatized hepatectomized animals utilized larger amounts of carbohydrate without insulin when their blood

sugars were maintained at high levels. Peters (1945), basing his opinion upon a large field of experimental work, comes to the conclusion that the reversal of the metabolic disorder in diabetic coma requires the use of every measure that will accelerate the utilization of carbohydrate. "Chief among these measures are the administration of insulin and the provision of sugar." Soskin and Levine (1944) calculated a large carbohydrate deficit and advised the administration of 500 g. of carbohydrate during the first twenty-four hours of treatment and one-half that amount during subsequent days in order to maintain normal stores of glycogen and carbohydrate metabolism.

Root (1945b), however, disagrees. He found a deficit of only 27 g. and stressed the point that there has been "an overestimation of the importance of an immediate restoration of glycogen stores in the liver." Franks *et al.* (1947) found that comparable doses of dextrose were retained more efficiently under much smaller doses of insulin when the blood-sugar level was normal than when it was considerably elevated. Mirsky's earlier work, suggesting that maintenance of hyperglycaemia would hasten the abolition of ketosis, is not borne out by Franks's clinical material. Pauls and Drury (1942), working on diabetic rats receiving large quantities of sugar and insulin, provided evidence that only a small part of the sugar was oxidized and that most of it was stored as fat. Drury (1940) showed that glucose may also be converted into fat when it is given at a rate exceeding calorific needs. Astwood's (1942) dogs, receiving glucose continuously at a rate exceeding their metabolic needs, died within 70 hours. Further, Bjerring and Iversen (1934) demonstrated that diabetic acidosis exaggerates the limitation of the power of the tubules to reabsorb glucose, and that there is poor retention of exogenous glucose in the presence of hyperglycaemia. Helmholz and Bollman (1940) produced a marked diuresis in response to high concentrations of glucose brought about by injection, and as a result hydropic degeneration of the tubules occurred and temporary anuria developed. Franks *et al.* (1947) showed a "striking difference" between the glucose and saline groups of cases in the handling of water and chloride. The fluid intake of the dextrose group was only slightly larger than that of the saline group, but the output was nearly four times as great, "largely because of an elevenfold difference in glucose output." Sunderman and Dohan (1941) found that hyperglycaemia causes the withdrawal of water from the tissues, and, conversely, that the administration of insulin, with the consequent fall in blood sugar, caused the transfer of water and electrolytes from the plasma to the tissues. In addition, cases of acidosis lost body water and electrolytes after the withdrawal of insulin (Atchley *et al.*, 1933).

The consistent high mortality for cases of diabetic coma in England due to circulatory failure and "intractable dehydration" led us to reconsider the value of the therapeutic measures employed, particularly with regard to the use of glucose and its effect on procedures adopted to correct dehydration.

Material

The West Middlesex is a hospital of 1,670 beds serving a wide area in south-west Middlesex. A large proportion of cases of diabetic coma are admitted as emergencies, never having been under the management of the physician in charge of the diabetic out-patient clinic. Only those cases which are unconscious and not responsive to external stimuli are considered cases of coma. All others, irrespective of the level of the blood sugar, are treated as cases of diabetic ketosis or pre-coma. The mortality in cases of diabetic pre-coma is negligible whether or not glucose is administered in the early stages of treatment.

The 28 consecutive cases of true diabetic coma which were admitted to this medical unit between September, 1944, and March, 1948, have been studied. Those cases admitted before February, 1946 (Group A), were given glucose throughout the first twenty-four hours of treatment, whereas cases admitted after that date (Group B) had no glucose until the blood sugar had reached normal levels or, alternatively, until the patient was able to sit up and drink the glucose without help.

Procedure

On receipt of information from the admissions officer a bed with electric blankets, enema and gastric lavage equipment, "cutting-down set" with pint flasks of normal saline, together with syringes and bottles for chemical investigations, are held in readiness. On arrival the patient is put to bed, surrounded by warm blankets. The diagnosis is confirmed and the severity of the attendant infection assessed. A gastric lavage and a cleansing enema are given while the house-physician cuts down on a vein, removes blood for chemical testing, injects insulin, and proceeds, as the ward sister finishes her work, to set up the intravenous drip.

Insulin.—The mental state of the patient and the severity of the concurrent infection determine the size of the initial dose of insulin, which is never less than 100 units. Where a patient's mental state is graded 4 (Collen) 200 units are usually administered, a quarter of it intravenously. Insulin is given at intervals of not less than two hours thereafter.

Fluids.—The Group A or glucose cases receive intravenous normal saline with 4.3% glucose, and Group B or saline cases receive normal saline intravenously until there is adequate correction of the hypochloruria, after which half-normal

definition of coma varies widely and there is no entirely satisfactory method of assessing the severity of individual cases. Timing the duration of coma is not always a simple matter, and it is difficult to obtain a history of exactly when, in the insidious course of diabetic ketosis, a patient lapsed from one mental state to another. Further, there is no definite evidence that the duration of coma up to about eight hours, taken by itself, correlates closely with the ultimate outcome. Collen's indices have been used, as they appear to be the most accurate available guide to prognosis (Collen, 1942). He computed his severity index by means of the following formula

$$\frac{30(\text{M.S.} + \text{C}) + 50 + \text{A} - \text{diastolic B.P.}}{4}$$

where M.S. is the mental state and C the complications.

M.S. is graded thus: 0 = conscious, 1 = drowsy, 2 = semi-conscious, 3 = unconscious but with response to pain, 4 = unconscious with no response to pain.

C is "complications," graded numerically from 0 to 5 in terms of danger to life. Grade 1 is "infection or other complication present" but of no real consequence. Grade 5 is "infection or other complication present" which by itself would seriously endanger life. Examples: Grade 1 — carbuncles (Case B1), pyelitis (Case B6); Grade 3 — lobar pneumonia (Case B14); Grade 5 — bilateral empyemata (Case B8).

A = Age in years.

Indices of over 60% are considered invariably fatal and those of below 30% bear a good prognosis. As Franks remarks, it would appear that only those cases in the "intermediate group are suitable for the evaluation of a therapeutic regimen."

saline is given. Every case receives not less than 2 pints (1.14 litres) of fluid intravenously in the first hour. In the older diabetic cases, or in cases in which cardiac embarrassment is expected, an intragastric drip is set up after the fourth to sixth hour, although altered blood may have been present in the stomach contents during lavage.

Glucose.—The saline cases do not receive glucose in the first four-hour period, and in the second four-hour period it is given only if the patient becomes fully conscious. In the third four-hour period glucose is always administered, usually by mouth. Not more than 100 g. is given over the first 24-hour period in any one case in the saline series. The glucose cases receive a standard solution of 4.3% glucose in normal saline, whether by vein, mouth, or intragastric drip.

Potassium.—Since the publication of Holler's (1946) case and the subsequent cases by Nicholson and Branning (1947) and by Martin and Wertman (1947), about 1 dr. (4 g.) of potassium chloride is left in the stomach after lavage in the most severe cases.

Results

A comparison of therapeutic results between different series of cases of diabetic coma is not always easy. The

Group A or Glucose Cases

Group A comprises ten cases ranging from 14 to 61 years, with an average of 35.9 years. Seven cases were in females. The figures given for the duration of coma are approximations. On admission all the cases described were unconscious and did not respond to external stimuli. Five cases responded feebly to a strong painful stimulus applied to the sole of the foot. Complications were few in this group and were mild in nature. The diastolic blood pressure ranged from 30 to 90 mm. Hg. Collen's formula was worked out and indices of between 23 and 58% (average 39.9%, mean deviation 10.2) were found. The four patients (Cases 1, 2, 5, 7) who died had indices of 57, 43, 53, and 58% respectively.

The initial blood sugar for the ten cases averaged 729.5 mg. per 100 ml., the lowest being 510 mg. and the highest 985 mg. The fall during the first four hours was calculated for each case: the readings for Case 5 rose, but the mean fall was 75.3 mg. per 100 ml.

Fluid intake for the survivors over the first 24 hours was 14.3 pints (8.13 litres), of which 9.5 pints (5.39 litres) were given intravenously and the remainder by other routes, such as by intragastric drip, by rectum, and by mouth. Glucose was administered in this group at the rate of 46 g. in the first hour,

23 g. in the second, and between 20 and 30 g. in the succeeding two hours. The average total glucose intake was 330 g. in 24 hours. The volume of the urinary output was measured in five cases. The output was 43.3% of the fluid intake.

The initial dose of insulin was either 100 or 200 units, with similar amounts given at two-hourly intervals until the readings showed definite signs of a fall. An average of 807 units was

The most significant result is that the mortality in Group A was 40% and in Group B 11%. Further, the fall in blood sugar in the first eight hours was more pronounced in the saline group and the output of urine (eight cases) was 21% of the total intake for the twenty-four hours, whereas in the glucose cases urinary output (five cases) amounted to 43% of the intake. Nearly 50% more fluid

* Case 5 received only two pints of fluid intravenously, the third and fourth pints having inadvertently dripped into the bedclothes. Nevertheless, the patient rehydrated adequately.

given to each surviving case in 24 hours. The urine became acetone-free in this group of cases in 13 hours (range 10 to 24)

Group B or Saline Cases

This group comprises eighteen cases ranging from 11 to 58 years, with an average of 33.3 years. Twelve cases were in females. Six cases fell into the most serious grading of mental state, whereas the remaining twelve responded to strong painful stimuli applied to the sole of the foot. The diastolic blood pressure fell in some cases, to dangerous levels. The lowest recording of 40/0 mm. Hg was for Case 8, who was nearly moribund. The highest readings, 135/80 mm. Hg, were in Case 18, whose pressures rose in convalescence to 185/110. There were all degrees of complications, eight being Grade 1, three Grade 2, three Grade 3, and one Grade 5. Case 15 had lobar pneumonia and Case 8 suffered from bilateral empyemata. These two patients (severity indices 60 and 86% respectively) died. Collen's indices for the whole group ranged from 26 to 86%, with an average of 41.6% (mean deviation 9.8).

The mean initial blood sugar was 865 mg. per 100 ml., the lowest being 542 mg and the highest 1,150 mg. The calculated fall in the first four hours was 339 mg. The total 24-hour fluid intake for the sixteen surviving patients was almost exactly 10 pints (5.68 litres), of which 5 pints (2.84 litres) were given intravenously. The total urinary output in those cases (eight in number) where the urine was successfully collected and measured amounted to 21% of the total 24-hour intake. The initial dose of insulin was either 100 or 200 units. Three hundred units were given in one case (100 intravenously), but the fourth-hour sugar reading was unfortunately lost. The average total dose of insulin given over 24 hours was 693 units. Acetone disappeared from the urine in 14 hours (range 11 to 24+).

The two groups of cases considered are of nearly equal severity and the age distribution is very similar. In other respects, such as depth and duration of coma, incidence of complications, level of diastolic pressure, and height of initial blood sugar, the groups of cases are comparable.

The procedure adopted in treatment throughout the first twenty-four hours was identical in the two groups except for the fact that Group B cases did not have glucose in the early stages of treatment.

was required to produce an adequate clinical state of hydration in those surviving cases given glucose.

Comment

There is a big difference in the mortality of two groups of comparable cases treated with and without glucose by what was otherwise the same therapeutic technique. Arguments in favour of the point of view that glucose is utilized at high blood-sugar levels, up to 2,000 mg. per 100 ml. (Wieruchowski and Bielinski, 1939), and that its administration in cases of coma restores carbohydrate metabolism, abolishes acidosis, and replenishes the liver glycogen would seem to be physiologically incontrovertible. Peters (1945) has made out a very good case for glucose administration on these grounds. Much of the literature and the mortality statistics relating to this controversy are from America, where cases described as those of coma include cases of what would be labelled pre-coma or ketosis in Britain. It would seem, therefore, that American authors dealing with large numbers of cases of ketosis and coma find that only a small proportion present as emergencies of dehydration.

It is possible that because of this there has been, as Root suggests, "an overemphasis of the importance of an immediate restoration of glycogen stores in the liver." The controversy is still being fought on physiological issues. The main point disputed is whether or not a patient in diabetic coma can utilize glucose at a high blood-sugar level.

Still undetermined are such subsidiary points as whether the endogenous glucose is sufficient for purposes of carbohydrate metabolism when insulin is supplied what quantities of glucose are retained at what level of blood sugar and under what doses of insulin, and whether or not the early administration of glucose abolishes ketosis more quickly. None of these points is by any means decided for the diabetic human being, although experimental animals with induced glycosuria give more or less conclusive results in favour of glucose utilization and glycogen restoration at high blood-sugar levels.

It is possible that the higher mortality for cases which were given glucose is not connected with the action of glucose on carbohydrate metabolism, which is probably beneficial, but on its interference with the process of cellular rehydration. The maintenance of hyperglycaemia induces an intense and prolonged glycosuria and, associated with it, a proportional diuresis. The urinary output bears a linear ratio to the glucose output (Franks *et al.*, 1947). The urinary output in our Group A cases was 43.3% of the total intake, and the fluid intake in these cases was 43% more than in the cases not given glucose.

The administration of glucose in the first four hours of treatment, by maintaining a heightened blood sugar, serves to increase water excretion, to worsen the state of cellular dehydration, and to add to the circulatory collapse and shock. This process may be of no great consequence in the milder cases, but where the clinical state of the patient is poor it may cause death.

The results of this study indicate that glucose should not be administered in the early stages of the treatment of diabetic coma. The withholding of glucose for at least the first four to six hours of treatment ensures rapid rehydration and decreases the mortality significantly in serious cases of coma with circulatory collapse.

Summary

A clinical study of 28 consecutive cases of diabetic coma treated with and without the early administration of glucose is described.

Ten cases received glucose and 18 only saline in the first four to six hours of treatment. The two groups of cases were comparable.

There was a mortality of 40% in the glucose cases and of 11% in the saline cases.

The results of this study indicate that the administration of glucose to serious cases of diabetic coma in the early stages of treatment interferes with rapid rehydration and increases the mortality significantly.

SUBACUTE PANCREATITIS

BY

IAN MACNAB, F.R.C.S.

Late Surgical Registrar, General Hospital, Birmingham

The most commonly recognized types of pancreatitis are the acute haemorrhagic form, with its dramatic clinical picture and high mortality rate, and the chronic type, with a long-drawn-out history of dyspepsia associated with general ill-health. Of the other degrees of pancreatitis, there is the variety which gives rise to a prolonged illness, with abscess formation, and the low-grade pancreatitis which may later progress to pseudocyst formation.

All these types are well known, but there remains another degree of the condition—subacute pancreatitis—which is not so widely recognized. Subacute pancreatitis is a fairly rapidly developing inflammation of the pancreas, generally associated with much oedema, which, though presenting as a surgical emergency, does not produce the same urgent clinical picture as is presented by the haemorrhagic form. There is a marked tendency to recurrence, and the initial attack is generally followed by several similar attacks over a period of time, producing the syndrome of recurrent pancreatitis. During one year at the General Hospital, Birmingham, there were 19 cases of subacute pancreatitis, of which 13 were recurrent attacks.

Pathology : Clinical Picture

At operation the gland is found to be enlarged and oedematous. The enlargement is sometimes very gross, and in three cases abdominal palpation revealed a mass which was found at operation to be an enlarged pancreas. In one instance the oedematous pancreas produced pyloric obstruction. The surface of the gland may present petechial haemorrhages and the peripancreatic lymph nodes are enlarged. There may be some free fluid in the peritoneum, but it is not blood-stained as in haemorrhagic pancreatitis. In two cases there was fat necrosis in the omentum.

The clinical findings are shown in Tables I and II. The patient, usually middle-aged and obese, develops upper abdominal pain which, though not severe at first, gradually increases in intensity over several hours until it is unbearable. The pain may be situated in the epigastrium or in the right or left hypochondrium. In some cases it is felt right across the abdomen under the subcostal margin. The pain, which may continue unabated for several hours, does not vary in intensity. When asked to describe the pain the patient generally states that it is deep-seated and boring in nature and that it passes through to the back. Vomiting occurs early, and when the stomach contents have been emptied incessant retching adds to the patient's distress. The temperature is normal, but the pulse rate is generally raised. There is some tenderness and guarding in the upper abdomen, and this may be present anywhere in the subcostal region. There is tenderness in one or both loins and in the costovertebral angles posteriorly. There are some inconstant signs, such as jaundice, due to obstruction of the common bile duct by the swollen pancreas, and occasionally glycosuria. In cases presenting recurrent attacks the clinical picture is similar, but vomiting is not severe, and the tenderness, when present, is only slight.

Laboratory Investigations

Only two of the multitude of investigations described for pancreatitis have proved of use in establishing the diagnosis—estimation of the level of the serum lipase and serum

TABLE I.—Summary of Clinical Findings in Patients Suffering from an Initial Attack of Subacute Pancreatitis

Case	Onset	Pain		Vomiting	Tenderness	Guarding	Jaundice	Glycosuria	Serum Amylase	Treatment
		Situation	Type							
1	Gradual; 24 hours	Epigastrium and through to back	Constant and deep-seated	Severe	Generalized; especially marked in epigastrium	Epigastrium	Nil	++	Urinary diastatic index 100 units	Conservative
2	Gradual; 48 hours	Epigastrium, right hypochondrium and through to back	"	"	Right and left hypochondria, costovertebral angles posteriorly	Right and left hypochondria Nil	Slight	Nil	438 units, two months later 51 units 32 units	"
3	Gradual; 5 days	Epigastrium, right and left hypochondria	"	Very severe	Left hypochondrium and left costovertebral angle	Nil	"	"	"	Laparotomy
4	Gradual; 4 days	Epigastrium and right hypochondrium	"	"	Right hypochondrium and right costovertebral angle	Right hypochondrium Nil	Nil	"	51 "	"
5	Gradual; 4 days	Epigastrium and left hypochondrium	"	Severe	Right hypochondrium, right and left costovertebral angles	Nil	Severe	"	190 "	"
6	Gradual; 8 hours	Left hypochondrium	"	Vomiting at onset severe, retching afterwards	Left hypochondrium and epigastrium	Nil	Slight	"	439 units; one month later 46 units	Conservative

TABLE II.—Summary of Clinical Findings in Patients Suffering from a Recurrent Attack of Subacute Pancreatitis

Case	Duration of Attacks	Pain		Vomiting	Jaundice	Glycosuria	Serum Amylase	Findings at Laparotomy
		Situation	Type					
7	5 years	Right hypochondrium and epigastrium	Constant and deep-seated	Severe	Slight	++++	36 units	Enlarged hard pancreas. Areas of fat necrosis in omentum
8	3 "	Epigastrium	" "	"	Nil	Nil	164 "	Enlarged firm pancreas. Areas of fat necrosis in omentum
9	3 "	Subcostal, through to back	" "	Occasionally	"	"	59 "	Enlarged hard pancreas
10	3 "	Subcostal	" "	Severe	"	"	245 units (during attack), 39 units three weeks later	Enlarged pancreas
11	6 "	"	" "	Never	"	"	258 units during exacerbation	" "
12	" Years "	Epigastrium	1½ hrs after meals, constant for 2 hrs	"	"	"	Not tested	Enlarged pancreas. Irregular "bosses"
13	2 years	Left hypochondrium	1 hr after meals, constant for 2 hrs	Severe	"	"	"	Enlarged pancreas. Areas of fat necrosis in omentum
14	18 "	Left hypochondrium and epigastrium	Constant and deep-seated	"	"	"	42 units	No laparotomy
15	15 "	"	" "	Occasionally	Severe	+++	Diastatic index urine, 6	Patient died. Enlarged fibrotic pancreas
16	10 "	"	" "	"	Nil	Nil	Not tested	No laparotomy
17	2 "	Right hypochondrium and right costovertebral angle	" "	Severe	"	"	59 units	Enlarged pancreas
18	2 "	Epigastrium	"Dragging"	Occasionally	"	"	504 units in exacerbation	" "
19	3 "	Subcostal	Constant and deep-seated	"	"	"	217 units in exacerbation	No laparotomy

amylase. Several estimations of the serum amylase have been made both in normal subjects and in patients suffering from various abdominal lesions. Somogyi (1932) stated that the normal limits were 80 to 180 units. Lewison (1941) gave 40 to 175 units as the normal range, and our results are more in keeping with those of Lewison than with those of Somogyi.

In the initial attacks the serum amylase is raised above normal and remains elevated until the symptoms have abated. In recurrent attacks the serum amylase is generally below normal, presumably because repeated attacks are associated with fibrosis of the gland and diminution of acinar tissue. Occasionally during an exacerbation the blood amylase is raised above normal and then settles to a subnormal limit later. This was found in three of the cases in this series.

The diastatic index of the urine follows the changes in the serum amylase level and is dependent upon the renal threshold for amylase being exceeded.

Diagnosis

The main features of subacute pancreatitis are: the deep-seated severe pain, which is of gradual onset and long duration, is situated anywhere in the subcostal region, and passes through to the back; the constant nature of the pain; the incessant vomiting and retching; the tenderness in one or both costovertebral angles; and, finally, the elevation of the serum amylase.

Differentiation from Perforated Gastric Ulcer

The clinical picture is as clear-cut as that produced by an acute appendicitis. An acute exacerbation of symptoms in a patient suffering from a chronic peptic ulcer may give rise to confusion, but the history and a normal serum-amylase level should make the diagnosis obvious. The dramatic picture presented by a perforated gastric ulcer differentiates it readily from subacute pancreatitis, though occasionally confusion may occur, as in the following case.

A man was admitted to the General Hospital on July 2, 1946, complaining of severe epigastric pain. He gave a history of attacks of pain in the left hypochondrium over the previous twelve years. The pain was of a constant nature and would continue unabated for 48 hours, uninfluenced by food and unrelieved by alkalis. Forty-eight hours before admission he had what he described as "a characteristic attack." The pain was continuous and constant for 24 hours and then subsided. Twelve hours later the pain recurred and gradually intensified to agonizing severity. He vomited twice at the onset of the pain, after which retching was incessant. On examination he was slightly jaundiced; there was epigastric distension, with generalized abdominal tenderness and guarding, but no rigidity. No tenderness was felt in the costovertebral angle. The serum amylase was 54 units, the blood sugar 270 mg. per 100 ml, and there was heavy glycosuria. A diagnosis of recurrent pancreatitis was made, but the patient was subsequently proved to be suffering from a perforated duodenal ulcer.

This case is unusual, however, and the differentiation of the two conditions should not prove difficult. Confusion has arisen with coronary occlusion, cholangitis, and

intestinal obstruction: however, in each case the history and signs differ in many points from those presented by subacute pancreatitis, and the serum-amylase level is within normal limits.

Confusion with Acute Cholecystitis

The condition most likely to give rise to confusion is acute cholecystitis, especially when subacute pancreatitis is associated with pain and tenderness in the right hypochondrium. The differential points to be borne in mind are the incessant retching which accompanies subacute pancreatitis, the tenderness in the costovertebral angles, and the rise in the serum-amylase level. Acute cholecystitis is often associated with a rise in temperature; this is not seen in subacute pancreatitis.

Undoubtedly many cases of subacute pancreatitis are incorrectly diagnosed as acute cholecystitis. Many of these cases are later subjected to an interval operation, and at laparotomy nothing abnormal is found. In such instances cholecystectomy may be performed with minimal pathological justification. On the other hand, evidence of a chronic cholecystitis may be found, and it has been stated that chronic cholecystitis is an aetiological factor in subacute pancreatitis. In such instances it is probably advisable to remove the gall-bladder, but it must be borne in mind that if the original condition was subacute pancreatitis and not acute cholecystitis, then the symptoms are apt to reappear.

Recurrence of symptoms after cholecystectomy is a condition so well known that a name has been given to it—the post-cholecystectomy syndrome. This syndrome may be produced by a stone in the common bile duct or by attacks of pancreatitis. This latter condition, though not generally recognized, is much more frequent than is commonly acknowledged. The following is a typical case.

This patient, aged 67, was admitted to the General Hospital suffering from jaundice. A cholecystectomy was performed in 1930, and since that date the patient had had attacks of pain situated in the epigastrium and left hypochondrium which would continue unabated from two to eight hours. Vomiting and retching and occasionally jaundice were associated with the attacks. During the month before admission the patient had had several such attacks and had become progressively more jaundiced. There was marked glycosuria and the diastatic index of the urine was 6 Wohlgemuth units. Death occurred shortly after admission, and necropsy revealed an enlarged fibrosed pancreas with dilated ducts.

Confusion with Gall-stone Colic

When subacute pancreatitis is associated with jaundice the condition may be confused with gall-stone colic. A careful consideration of the history and physical findings taken in conjunction with the level of the serum amylase would differentiate the two conditions. In this respect the following case of subacute pancreatitis is of interest.

Case 5 (see Table I).—This patient, a young woman, was admitted to the General Hospital on Sept. 19, 1945, with a history of attacks of epigastric pain over the previous ten days, increasing in severity. The pain was constant in nature and was associated with severe vomiting. Four days before admission the patient became jaundiced. On examination she was deeply jaundiced; the abdomen was flaccid, with guarding and tenderness in the right hypochondrium and tenderness in the costovertebral angles posteriorly. A radiograph revealed a shadow in the gall-bladder area which was reported as being possibly due to a gall-stone. The serum amylase was 190 units. A pre-operative diagnosis of cholecystitis was made, but laparotomy revealed a normal gall-bladder with no evidence of calculi. The pancreas was swollen, congested, and oedematous, and the peripancreatic lymph glands were enlarged. The patient made an uneventful recovery. Four weeks later the blood amylase was 80 units.

Treatment

The treatment of subacute pancreatitis is conservative. Rest in bed should be enforced until symptoms have subsided. Large doses of morphine may be necessary in the first few hours to give the patient relief from pain, but apart from this no other special medical treatment is indicated. When there is a history of recurrent attacks of subacute pancreatitis the gall-bladder should be investigated, and if there is any evidence of chronic cholecystitis cholecystectomy should be performed, as it is very probable that the diseased gall-bladder is acting as the focus of infection for the recurrent attacks of pancreatic inflammation.

Typical Case Reports

The following two cases are reported in full as being typical of the conditions described.

Subacute Pancreatitis (Case 6)

A middle-aged man was admitted to the General Hospital on Dec. 28, 1945, complaining of severe pain in the left loin and left hypochondrium. The pain was described as being deep-seated and passing through to the back. It later radiated to the right hypochondrium. The patient vomited at the onset of the attack and had suffered from severe retching throughout.

On examination he was jaundiced and was tender on deep palpation in the left hypochondrium, the epigastrium, the left loin, and the left costovertebral angle. The serum amylase was 439 units and the serum bilirubin 6 mg. per 100 ml. He settled down on conservative treatment, and a month later his blood amylase had fallen to 46 units.

Recurrent Pancreatitis (Case 7)

A man was admitted to the General Hospital on Nov. 21, 1941, complaining of intermittent attacks of epigastric pain over the previous eight weeks. The pain was continuous and was unrelated to food. The attack immediately before admission had continued for four days, during which time he had vomited incessantly. A diagnosis of subacute intestinal obstruction was made. A laparotomy was undertaken, but failed to reveal any abnormality. The patient made an uneventful post-operative recovery.

On Nov. 21, 1942, he was readmitted complaining of an exactly similar attack of only two hours' duration. A diagnosis of perforated gastric ulcer was made, but laparotomy revealed no abnormality in the stomach. The pancreas was swollen greatly and was very hard. He again made an uneventful post-operative recovery.

On May 5, 1944, a similar attack occurred and the patient was readmitted to hospital. A diagnosis of subacute obstruction due to severe constipation was made. It was noticed that he was suffering from severe diabetes.

On April 12, 1946, he was readmitted after an exactly similar attack. On examination he was tender in the epigastrium, in the left hypochondrium, and in both costovertebral angles. The blood sugar was 235 mg. per 100 ml. and the blood amylase was 36 units. The patient progressed well on conservative treatment and was discharged in ten days.

I am convinced that Case 7 was a clear-cut instance of recurrent pancreatitis. The low level of the serum amylase is in keeping with the fibrosis which must have occurred in the pancreas.

Conclusion

Subacute pancreatitis has a clinical picture as clear-cut as that presented by a perforated gastric ulcer. The diagnosis, though it may readily be made by consideration of the history and physical signs, is confirmed by the changes in the serum-amylase level.

The possibility of subacute pancreatitis must always be borne in mind when diagnosing an abdominal emergency, especially acute cholecystitis. Confusion of the condition with cholecystitis accounts for many of the cases of recurrence of symptoms following cholecystectomy. This error

in diagnosis would largely be obviated if serum-amylase investigations were more often employed in elucidating obscure cases of upper abdominal pain.

Subacute pancreatitis is not a rare condition, and its diagnosis depends largely on being aware of the existence of this clinical syndrome.

Summary

Subacute pancreatitis is a clinical entity readily differentiated from acute haemorrhagic pancreatitis and other abdominal emergencies.

Patients suffering from this condition present as an acute abdominal emergency but settle down on conservative treatment.

The condition is very apt to recur. Of the 19 cases presented 13 were recurrent attacks.

It is suggested that estimation of the serum-amylase level should be more widely employed to differentiate this condition from other acute abdominal lesions.

I would like to thank Professor F. A. R. Stammers for his help in presenting this paper

REPORT ON AN OUTBREAK OF INFLUENZA IN THE ARMY

BY

D. G. MILNE, M.B., Ch.B.
Major, R.A.M.C.

AND

J. D. CRUICKSHANK, M.B., M.R.C.S.
Lieutenant-Colonel, R.A.M.C.

During the months of January and February, 1949, several Army units in Mid-West District, which comprises the whole of Wales and the adjoining English counties, reported that cases of influenza were occurring among their personnel. The first cases to be diagnosed as influenza occurred on Jan. 19 in units stationed at Malvern. The second unit affected was a Boys' Battery of the Royal Artillery, near Rhyl, on Jan. 24. On Jan. 31 cases were reported at Lichfield and on the following day at Donnington. Oswestry garrison were the next victims, on Feb. 7, and by Feb. 21 cases were also being reported from Nesscliffe, near Shrewsbury, Wrexham, and Tonfanau, on the Welsh coast. A total of 646 cases were notified from all Army units in Mid-West District from the start of the outbreak on Jan. 19 to Feb. 21.

Features of the Outbreak

It had been previously impressed upon all ranks that if an epidemic of influenza did occur it was of prime importance to report sick early. Nearly all soldiers affected attended their medical officer within a few hours of experiencing their first symptoms. It is interesting to note that, in one instance only, a soldier remained in his barrack room for over 24 hours before reporting sick. Eighteen out of twenty of his comrades in the same hut developed influenza later.

The main features were a sudden onset with frontal headaches, a transient sore throat without lymph-node enlargement or tenderness, a slight cough, and a feeling of general weakness and lassitude, coupled with aches and pains in the arms and legs and in the lumbar region. Mild rigors preceded the rise in temperature, which was in the neighbourhood of 103° F. (39.4° C.), although a few cases did develop temperatures of 105° F. (40.6° C.). Circumoral pallor, injection of the conjunctivae, and profuse nasal discharge were absent. Epistaxis occurred in a few cases at Lichfield, but was not a common feature. The temperature gradually

dropped, and by the fourth day of the disease most patients were apyrexial. Chest complications did not occur and after-effects were absent amongst the great majority of male patients. In the few cases occurring in the W.R.A.C. or A.T.S., however, lassitude and post-influenzal depression were noted.

Patients were treated in camp reception stations until their temperature subsided, and were then transferred to barrack accommodation for a convalescent period of two days before starting duty. The average duration of the illness from the initial symptoms until return to full duty was between six and eight days.

Treatment.—This was of a palliative nature. Warmth, rest in bed, and plenty of fluids by mouth were the main principles adopted. Salicylates and Dover's powder were given during the pyrexial period, and codeine if the cough proved troublesome.

Laboratory Investigations

When it was obvious that a definite outbreak had occurred each garrison was visited and throat washings in 10–15 ml. of sterile saline were taken from selected cases. Febrile patients or cases in the early stages of the illness were chosen so far as was possible. The washings were packed in ice and delivered within six hours to the Central Public Health Laboratory, Colindale, and the National Institute for Medical Research, Hampstead, where they were examined for the presence of virus. Broth was not added to the washings: the addition of 5 ml. would have improved the chances of recovering the virus.

The first of the paired sera required for the Hirst and complement fixation tests was taken at this visit. This was held in the refrigerator at 2–3° C. until the second of the pair was taken, on the twelfth to fourteenth day of the disease.

The sera were examined by Dr. A. P. Goffe at the Central Public Health Laboratory, Colindale; the results are indicated in brief in the tabulated schemes which follow.

TABLE I—Cases at Rhyl (all males)

Case No.	Age in Years	Symptoms					Temperature on Day of Disease
		Shivering	Head-ache	Sore Throat	Cough	Muscle Pains	
1	16½	++	+	+	+	—	100.8° F.: 1st (38.2° C.)
2	15½	++	+	+	+	—	101.6° F.: 1st (38.7° C.)
3	20	++	++	+	+	±	97.0° F.: 3rd (36.1° C.)
4	17½	++	+	—	+	+	98.0° F.: 4th (36.7° C.)
5	16½	—	++	+	+	±	97.5° F.: 3rd (36.4° C.)
6	16	+	++	++	+	—	98.0° F.: 4th (36.7° C.)

Saline Washings.—Report on Feb. 2 1949: Type A virus isolated in two cases from washings taken on Jan. 28, 1949.

Hirst Test.—Four cases showed fourfold rise of antibody inhibiting foal red-cell agglutinin (A PR 8) in second serum. Two cases in which the first serum (taken on the fourth day of illness) showed a high titre (1 in 48) had a twofold rise on the 14th day in antibody to A PR 8 agglutinin.

C.F.T.—Second sera showed 16- to 64-fold rise in complement-fixing antibody to Type A strain antigen.

Result.—Influenza type A.

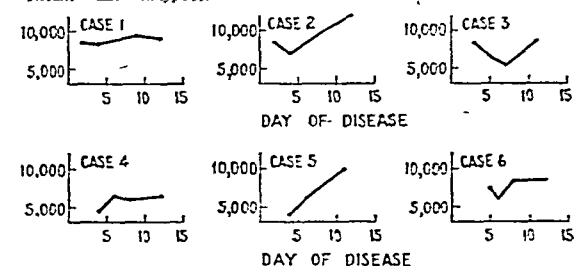

Chart showing the white cell count of the Rhyl cases (see Table I).

TABLE II.—Cases at Lichfield (all males)

Case No.	Symptoms						Temperature on Day of Disease
	Age	Shivering	Head-ache	Sore Throat	Cough	Muscle Pains	
1	18	—	—	Dry	+	—	101.6° F.; 2nd (38.7° C.)
2	18	—	+	Dry	+	+	101.0° F.; 2nd (38.3° C.)
3	19	+	—	Dry	+	—	98.4° F.; 2nd (36.9° C.)
4	22	+	+	+	—	+	102.8° F.; 1st (39.3° C.)

Saline Washings.—Virus was not isolated from these washings.
C.F.T.—Second sera showed 4- or 8-fold rise in titre of complement-fixing antibody to Type A strain antigen.
Result.—Influenza type A.

TABLE III.—Cases at Donnington (all males)

Case No.	Symptoms						Temperature on Day of Disease
	Age	Shivering	Head-ache	Sore Throat	Cough	Muscle Pains	
1	19	+	+	—	—	+	99.6° F.; 3rd (37.5° C.)
2	18	+	+	—	—	+	99.8° F.; 3rd (37.7° C.)
3	18	+	+	—	—	+	98.0° F.; 3rd (36.7° C.)
4	19	+	+	—	—	+	100.0° F.; 2nd (37.8° C.)
5	20	—	+	—	+	+	100.2° F.; 3rd (37.9° C.)
6	19	+	+	—	+	—	100.8° F.; 3rd (38.2° C.)
7	20	+	—	+	+	—	100.2° F.; 5th (37.9° C.)
8	18	+	+	—	+	—	99.4° F.; 3rd (37.4° C.)

Saline Washings.—Type A strain of virus isolated in one case from washings taken on Feb. 9, 1949.
C.F.T.—Second sera showed 8- to 32-fold rise in titre of complement-fixing antibody to Type A strain antigen.
Result.—Influenza type A.

Complement fixation tests on sera from four cases at Malvern showed results with Type A strain antigens similar to those in the Tables.

Preventive Measures

Early diagnosis and rapid isolation of the patient were aimed at in order to check the spread throughout each unit. Strict attention was paid to the adequate ventilation of barrack rooms and to the spacing of beds to the optimum. General measures on the maintenance of the health of the troops, the shaking and airing of blankets in the open, and the sweeping of floors, previously sprinkled with water, were adopted. Routine gargling and the spraying of rooms with disinfectant were not carried out, nor was prophylactic inoculation attempted. Unit cinemas were closed for a short time in two areas at the height of the outbreak, but the numbers of cases occurring did not warrant restricting movement of troops or cancelling the intake of National Service men to training establishments.

The movements of the first three cases occurring in each unit prior to the onset of symptoms were investigated, with, however, inconclusive results. No direct connexion with the European epidemic could be traced.

Summary

An outbreak of influenza of the Virus A type occurring in Army units in Wales and the West Midlands is reported. Symptoms, treatment, laboratory investigations, and preventive measures adopted are described.

Our thanks are due to Lieutenant-General Neil Cantlie, C.B., M.C., K.H.P., Director-General Army Medical Services, and Major-General R. W. Galloway, C.B., C.B.E., D.S.O., K.H.S., D.D.M.S. Western Command, for permission to publish this report.

SPONTANEOUS INTRA-ABDOMINAL HAEMORRHAGE

BY

A. L. WOOLF, M.B., B.S.

AND

H. R. THOMSON, M.D., M.R.C.P.

(From the Central Middlesex County Hospital,
Park Royal, London)

Spontaneous intraperitoneal haemorrhage—i.e., that occurring without any obvious cause such as cirrhosis of the liver (James, 1930) and rupture of aneurysm—has been recorded in 26 cases*—19 collected by Berk, Rothschild, and Doan† (1941), three reported by Marks and Freedlander (1945), and one each by Keusenhoff (1934), Matheson (1934), Crile and Newell (1940), and Haugen (1944).

In only eight of these cases were necropsies performed. In Keusenhoff's case and in two cases recorded by Moorehead and McLester (1936) a definite arterial rupture was found; but in the remaining five no single vessel could be held responsible, though in Matheson's case the haematoma was related to the branches of the ileocolic artery. Four of the cases had clinical or morbid anatomical evidence of hypertension (Moorehead and McLester two, and the fatal case of Marks and Freedlander) or arteriosclerosis (Keusenhoff). Haugen's case, which followed appendectomy, like those of Matheson (1934), Churchman (1911), and Hartley and MacKechnie (1934), showed no evidence of vascular disease, but in these cases blood-pressure readings before the catastrophe or reports on the histology of the kidneys are lacking.

Three cases of spontaneous abdominal haemorrhage, two of which included a haemoperitoneum, are described below.

Case 1

A woman aged 58 was admitted with a four-months history of discharging ear (? cerebral abscess). She had had pain in the left hypochondrium for one month accompanied by vomiting when severe. Investigations before admission showed: haemoglobin, 66%; leucocytes, 17,300 per c.mm. (89% neutrophils); serum Wassermann reaction, negative.

On examination the temperature was 99° F. (37.2° C.), pulse 110. She had a profuse discharge from the right ear, and diplopia on looking above the horizontal. The abdomen appeared normal. The B.P. was 140/80. Leucocytes numbered 43,000 per c.mm. Two days after admission she had severe upper abdominal pain and urge to defaecate, but the bowels were not opened. On examination she was pale, the pulse was 160, and there was extreme tenderness in the upper half of the abdomen. She died in less than an hour.

Necropsy.—Intracranial disease was not discovered. Very marked purulent bronchitis and emphysema were found. On opening the abdomen large blood clots were seen in the peritoneal cavity. The greater omentum and lesser sac also contained blood clot. Careful dissection of the branches of the coeliac axis, the superior mesenteric artery, and the tributaries of the portal vein failed to reveal any macroscopic evidence of structural change in their walls or of thrombosis. Smaller vessels within the area of haemorrhage in the pancreas were also minutely examined without any abnormality being detected. Both renal arteries contained thrombi, the kidneys appearing very pale but otherwise normal. The bowel contents were black, but there was no macroscopic lesion in the intestinal mucosa.

Histology.—Omentum:—A huge area of haemorrhage occupied the omental fat tissue, which included a central area of

*Since submission of this paper a case of malignant hypertension with haemoperitoneum has been published by De Navasquez and French.

†The case of Florence and Ducuing (1913) was traumatic.

haemorrhagic necrosis. This area was surrounded by macrophages containing haemosiderin. Outside the haemorrhagic areas the arterioles showed fibrinoid thickening of the intima, and collars of lymphocytes, eosinophils, and macrophages. In addition, several islets of haemopoiesis were found. *Myocardium*:—Only the vascular changes were striking. The arterioles showed subintimal swelling, sometimes in the form of appositional loosely woven pink cushions and sometimes in the form of intensely eosinophil hillocks over which endothelial cells appeared unusually prominent and sometimes detached. *Spleen*:—There was very extensive and marked hyaline fibrinoid infiltration of walls of arterioles with reduplication of elastic laminae of some vessels. *Pancreas*:—Marked hyalinosis of arterioles was present. Stroma was rich in fat grapes and contained extensive areas of haemorrhage. *Stomach*:—Arterioles of outer layers of wall, outside and in the periphery of blood clot, showed marked hyaline fibrinoid infiltration. Innumerable collagen shreds could be seen in the clot. *Kidney*:—A fair number of glomeruli showed hyalinosis of the afferent arterioles. Many glomeruli appeared enlarged, with fusion and hyalinization of loops and increase in nuclei. There were tubular casts but no crescent formation. An occasional glomerulus showed fibrinoid change in some of its loops. Another section showed several collections of lymphocytes, the most conspicuous being around a hyalinized vessel the lumen of which was completely occluded by hyaline material, part of which showed fibrinoid change.

Comment.—Necropsy revealed no intracranial lesion and no source for the haemorrhage. Histologically there were widespread arteriolar thickening and kidney changes, as normally seen in hypertension, to which the massive intraperitoneal haemorrhage may therefore be attributed, in spite of the readings, which were, however, taken only after the onset of the disease. That the arteriolar changes may have given rise to the haemorrhage is possible, especially as similar lesions occurring in dermatomyositis have been shown (Pagel, Woolf, and Asher, 1948) to lead to extravasation of blood, though this was admittedly microscopic. Goldblatt's (1938) finding of petechial and larger haemorrhages in dogs with experimental malignant hypertension provides further support. The petechial haemorrhages in such cases were associated with dissection of necrotic or hyalinized arteriolar walls by red blood corpuscles. On the other hand, the possibility of a haemorrhagic diathesis may be considered, although Bruce's (quoted by Berk, Rothschild, and Doane, 1941) similar case with recovery was subsequently investigated for bleeding tendency without success. Multiple small discrete haematomata in the greater omentum and mesentery in Hartley and MacKechnie's case, however, suggest that their patient may have had a haemorrhagic diathesis.

The following case of abdominal haemorrhage affecting chiefly the ilio-psoas muscle, though lacking a haemoperitoneum, showed in other respects a striking resemblance to Case 1, and is therefore included.

Case 2

A woman aged 65 had had rheumatoid arthritis for eight years, and recently the onset of dyspnoea, nycturia, and swelling of the feet. On examination myxoedema, congestive cardiac failure, and advanced rheumatoid arthritis were found. The B.P. was 180/100. She collapsed and died two days after admission.

Necropsy.—Very pale and thin body. Basilar artery and circle of Willis showed severe atheroma. Right pleura adherent and oedematous, with numerous small haemorrhages (up to 0.4 cm. diameter), marked left ventricular hypertrophy, and atheroma of endocardium below aortic valves. Severe atheroma of coronary arteries. Femoral arteries showed medial sclerosis. Kidneys granular, with variegated cortex. There were extensive areas of intramuscular haemorrhage up to 5 by 4 cm. diameter in the superficial portions of the rectus abdominis and in the ilio-psoas muscles.

Histology.—*Psoas muscle*:—There was a massive haemorrhage beneath the fascia but no appreciable haemorrhage in the muscle itself. In addition to the extensions of the extravasation along the interfascicular stroma there were striking cellular and muscular changes. (a) The cellular changes consisted of dense perivascular and interstitial infiltration with plasma cells and lymphocytes, the former being predominant around the vessels, which, though for the most part appearing normal or showing slight fibrous thickening, occasionally showed intensely eosinophil eccentric intimal cushions as described in the myocardium in Case 1. (b) The muscular changes occurred only between the strata of extravasated blood, and consisted of vacuolation and shrinking of sarcoplasm with evidence of cellular regeneration. *Heart muscle*:—Conspicuous eccentric subintimal cushion formation in small arterioles. *Kidney*:—Extreme glomerular hyalinization of the wire-loop type, many glomeruli being completely atretic. There was also atrophy of the renal tubules.

Comment.—The presence of severe arteriolar disease and the clinically observed hypertension suggest a primarily vascular cause for the haemorrhages in this case. This is corroborated by the confinement of the pictures of muscular degeneration to the haemorrhagic areas. The perivascular, lymphocytic, and plasma-cell cuffing in the area of haemorrhage in these two cases is probably a local reaction to the latter, and is described in cases of perirenal haematoma by Heilmann (1930).

Case 3

A man aged 63 was admitted two hours after an acute onset of pain in the right hypochondrium radiating to the right scapular angle. The pain was dull and continuous, and he felt as though blown up with wind. There was slight nausea but no vomiting. A similar attack a year previously, diagnosed as a coronary thrombosis, cleared up after a week in bed.

On examination he was seen to be obese and pale, and he was sweating. The pulse was 72, temperature 97° F. (36.1° C.), and respirations 20. The blood pressure was 220/125. The abdomen was distended and tympanic, without shifting dullness. There was tenderness but no rigidity in all areas, most pronounced in the right upper quadrant and extending round the flank to the right loin. Peristalsis was diminished. Rectal examination showed no abnormality and the urine was normal. On two occasions after admission he suddenly became shocked and his blood pressure fell to 60/40 but with a pulse rate of only 80. On each occasion he recovered in a few hours. On the afternoon following admission the tenderness and the gnawing pain were localized to the right iliac fossa. Laparotomy was performed for "acute appendicitis." There was much free blood in the peritoneal cavity and adhesions were present, mainly on the right side. In the right iliac fossa a fresh retroperitoneal haematoma was spreading towards the right loin, and a large boggy swelling was palpated in the position of the right kidney. Death occurred 30 hours after operation.

Necropsy.—Short, fat man. Right pararectal operation wound. *Heart*:—Weight, 800 g.; left ventricular hypertrophy. *Aorta*:—Gross atheroma. Peritoneum contained 60 oz. (1.7 litres) of fresh blood; omentum adherent to anterior abdominal wall. *Intestines*:—Gross distension; coil of terminal ileum adherent to pelvic peritoneum and obstructed by an omental band. Adhesions between gall-bladder and transverse colon. There was a large blood clot in the right perirenal fat which extended to the splenic flexure. The right suprarenal gland was expanded by a dense blood clot; external measurements 7 by 3 by 3 cm. The right kidney was surrounded by blood clot but was normal, apart from autolysis, and its capsule was intact. The renal artery was free from thrombosis, but the suprarenal artery could not be identified owing to the advanced autolysis.

Histology.—Suprarenal gland:—wholesale necrosis of the cortex, also of the capsular fat tissue. Some islets of parenchyma were still preserved in the central areas, where there was fibrinoid infiltration of the septa. With staining for elastic tissue the outlines of vein walls were visible in the centre of the blood clot.

Comment.—Perirenal haematoma was first described by Wunderlich (1856) under the title of "Apoplexie des

Nierenlagers," and was later classified into four categories by Ponfick (quoted by Coenen, 1910). Case 3 is an example of Ponfick's haematoma renis extracapsulare. Coenen, who collected 12 cases of perirenal haematoma and reported one of his own, mentions nephritis, renal sarcoma, arteriosclerosis, renal tuberculosis, chronic splenomegaly with gastritis, and haemophilia as the associated conditions. Heilmann (1930), who reported four cases of perirenal haematoma, suggests spasm of the capsular vessels as an aetiological factor. Cases of gross suprarenal haemorrhage have been reported in adults (Keele and Keele, 1942; Burnett, 1948). Eleven cases had previously been described. Only three of these cases, including those of Keele and Keele, were unilateral, as was the case under discussion, and in no instance was there a haemoperitoneum. In addition to atheroma and a possible spastic mechanism owing to hypertension, thrombosis of the suprarenal vein as in Keele and Keele's case should be considered as the proximate cause.

Summary

Three cases of intra-abdominal haemorrhage are reported. All three had evidence of hypertension.

The first case was one of spontaneous intraperitoneal haemorrhage with no morbid anatomical source for the bleeding apart from hypertensive changes in the smaller vessels.

The second case showed intramuscular haematoma; hypertensive arteriolar disease was sufficient to account for the haemorrhage.

The third case showed a haemoperitoneum from rupture of a perirenal haematoma. The origin of this is discussed. There was clinical evidence of severe hypertension.

Our thanks are due to Dr. W. Pagel for provision of material and assistance in preparation of this paper, to Dr. R. J. Porter, Dr. R. A. J. Asher, and Mr. J. D. Fergusson for the use of the clinical notes, and to Mr. L. Spain for histological assistance.

The British Council for the Welfare of Spastics has produced an admirable pamphlet entitled "Notes for Parents on the Home Care of Children Handicapped by Cerebral Palsy." It has been prepared by Dr. J. H. Crosland, of the Physical Medicine Department, Haring Cross Hospital, and Mr. H. P. Weston, executive secretary of the council. After a short account of the causes and nature of cerebral palsy the authors describe in detail how to care for spastic and athetoid children, while emphasizing that they must not be coddled. While these children must receive what help they need, the parents' natural anxiety should not prompt them to make their children over-dependent. Self-confidence and a sense of security must be inculcated into the children, and there are illustrations of special furniture, toys, and feeding utensils that will help the children to live as independently as possible. Special sections are included on the training of speech and excretion. Particulars may be obtained from the council's honorary executive secretary at 107, Norfolk Avenue, Sanderstead, Surrey. The pamphlet is obtainable from the same address for 1s. 3d. post free.

EFFECT OF PRESSURE COOKING ON VITAMIN C CONTENT OF VEGETABLES

BY

GWENETH M. CHAPPELL, M.Sc.

AND

AUDREY M. HAMILTON, B.Sc.

(From King's College of Household and Social Science, University of London)

We have recently been investigating the effect of pressure cooking upon the loss of vitamin C in vegetables. As it may be some time before we can continue this work, and as there is considerable topical interest in the question the results so far obtained are here briefly reported.

Method

In order that the results may be interpreted readily, we have compared the effects of pressure cooking with those of cooking in an ordinary saucepan. Since it is known that factors such as the volume of water and the period of cooking greatly affect the loss of vitamin C in the saucepan, the method adopted was that known to conserve the vitamin as much as possible. This method, advocated by the Ministry of Food, involves the use of a small volume of water, bringing this to the boil before putting in the vegetable, and cooking for the minimal time. With one exception, 200 g. of vegetable was cooked in 200 ml. of water in the saucepan, as this was found to be the minimum amount of liquid necessary to prevent the saucepan boiling dry. The exception was spinach, to which, as in common practice, water was not added.

The pressure cooker used was one of the now popular variety with a capacity of 7 pints (3.96 litres). The vegetables were cooked in this according to the directions supplied by the manufacturer. Again 200 g. of vegetables was used, but only 100 ml. of water. A larger volume of water is unnecessary, and would undoubtedly result in a greater loss of vitamin C by leaching. Care was taken to avoid overcooking with either method.

In every experiment six samples of each raw vegetable so far as possible equivalent and representative, were taken. Two were for the determination of the initial content of vitamin C, two for the pressure cooking, and two for saucepan cooking. Two different portions of each raw sample of vegetable and three of each cooked sample were taken for analysis. The vitamin C was also assayed in the cooking-water. Thus for every experiment 20 samples were assayed, each assay being made in duplicate. In all, 14 experiments were performed on 10 different vegetables. The method of estimation used was that of Harris and Olliver (1942).

Results

In view of the varying nature of different vegetables and of different specimens of the same type, it was not to be expected that the variation in results between the two methods of cooking would be uniform. In all of the 10 vegetables examined there was no evidence that saucepan cooking was better than pressure cooking in retaining vitamin C. In six vegetables—cauliflower, broccoli, winter cabbage, new carrots, turnips, and swedes—the retention was consistently better in pressure cooking by between 3 and 28% of the original amount of vitamin C. In the other four vegetables—spring cabbage, broad beans, old carrots, and spinach—pressure cooking gave a slightly higher retention in some experiments and a slightly lower retention in others. The average difference in

these instances was always small—of the order of 5% in favour of the one or the other method. The average retention of the original vitamin C in all the experiments performed was 7.5% more in pressure cooking than in saucepan cooking—66% against 58.5%.

The estimations of vitamin C in the cooking-water showed that, with the exception of spinach, there was a greater loss by leaching in the saucepan than in the pressure pan. The results with spinach were no doubt due to the fact that no water was added to the saucepan, whereas 100 ml. was added in the pressure cooker. It is often recommended that the water used in cooking vegetables should be used in soups, stews, and gravies. This is, however, not often done, and when it is the liquid is frequently kept for some time and then cooked again. If it were to be used immediately the difference in the total ascorbic acid in the vegetable and cooking-water together would be negligible when comparing the two methods of cooking. In other words, the total amount of the vitamin in the vegetable and cooking-water together was on the average almost the same in the two forms of cooking (78% pressure cooking; 79.6% saucepan cooking).

Discussion

This investigation is of necessity limited by difficulties peculiar to any attempt to bring laboratory methods to domestic problems. On the one hand, it is clearly necessary to control as many factors as possible by using standardized conditions; on the other hand, it is obvious that no two housewives will cook in identical conditions; in fact, these conditions will differ from time to time even in one kitchen.

In the controlled conditions we have used it is evident that, so far as the retention of vitamin C is concerned, pressure cooking is certainly no worse than cooking in a saucepan, and in some instances is better. The differences are small, however, so that a bad technique with either method would result in a greater loss of the vitamin with that method. In some of our work, overcooking in the pressure cooker or a longer time in reaching the necessary pressure led to an appreciably greater loss of vitamin. Again, in what is still, unfortunately, the common way of cooking vegetables in a saucepan, with large volumes of water and a tendency to overcook, there is a greater loss of vitamin C than in the Ministry of Food method used in these experiments. It is probable, therefore, that either type of cooking in the home will often cause greater loss of vitamin C than in our experiments. This is more likely to occur when the saucepan is used: overcooking of vegetables in the pressure cooker results so easily in disintegration that housewives soon learn to avoid this, whereas slight overcooking with a large volume of water in the saucepan results in no obvious loss in appearance or palatability. We may reasonably conclude that, in general, the retention of vitamin C in vegetables in pressure cooking is likely to be no worse, and will probably be better, than in the saucepan when either process is used in the home. There is certainly no reason, from our experiments, to suppose that pressure cooking should be discouraged because of its effect upon the nutritive value of vegetables.

So far as other foods and vitamins are concerned, very little has been published. A few experiments of our own on the vitamin B₁ content of pulses suggest that the pressure cooker is better than the saucepan.

Summary

A comparison has been made of the effect upon the retention of vitamin C in 10 different vegetables when cooked in a modern pressure saucepan and in an ordinary saucepan according to the recommended methods. On the average the

retention was higher in vegetables cooked in the pressure cooker.

We should like to thank Professor John Yudkin for his counsel and the Ministry of Food for cooking some of the samples.

SPERMATOLYSIS: A CAUSE OF MALE STERILITY

BY

CAFER YILDIRAN, M.D.

Urological Surgeon, Trabzon-Numune Hospital; member of Turkish Medical Society; British Council Student in Urology

Much attention has been directed of late towards the problem of sterility and infertility. In consequence I have been stimulated to present the results of some studies on male sterility which suggest a causative factor not hitherto described.

During the investigation of 75 males complaining of sterility at the urological clinic of Dr. A. E. Gussel, in the Guraba Hospital, Istanbul, I came across two specific abnormal spermatozoon types which were thought to be the cause of the sterility. The purpose of this communication is to call attention to the abnormalities. Short summaries of five of the case histories are given.

Case Reports

Case 1.—H.T., married five years; no children; wife pronounced normal by the gynaecologist. No history of venereal disease. No physical abnormality present. Examination of sperm 30 minutes after collection showed no microscopical or macroscopic abnormality. After two hours the specimen was separating into two layers—a clear supernatant and a sedimented layer. Microscopically the clear layer was acellular, but the sediment contained aggregations of dying spermatozoa. (I intend to make some observations on the death of spermatozoa in a further paper.) As time passed fewer and fewer sperms were seen, until at the end of six hours none were visible—the phenomenon of spermatolysis. Furthermore, the fluid obtained from this patient by prostatic massage caused spermatolysis to occur in the semen of a normal control when added to the latter.

Case 2.—N.O., married four times in the previous twenty years. One of his former wives had remarried and had had a family. No previous venereal disease, and no abnormal physical findings. The seminal fluid appeared to be more viscous than normal, but microscopically it seemed normal in every way up to two hours, when agglutination was beginning. After six hours spermatolysis was complete as in Case 1, and again prostatic fluid from this case caused spermatolysis when added to a normal control seminal fluid.

Case 3.—H.D., aged 34; married eight years; no history of venereal disease; wife normal. A spermogram showed oligospermia and hypokinesia. In two hours spermatolysis was complete.

In these three cases aspiration of the epididymis was performed. Unfortunately no sperms were found in any of the specimens, but in Case 3 minute comma-shaped bodies about 2 by 4 μ were seen. They showed some brownian movement. I got the impression that they were microsperms. Within two hours they had undergone lysis. In normal cases spermatozoa aspirated from the epididymis live two to three days.

Case 4.—F.O., aged 32; married three years; history of gonorrhoea twice, with clinical cure; no evidence of epididymitis or prostatitis; wife normal. Semen appeared normal

but showed asthenospermia microscopically. In five hours spermatolysis was complete, but in this case the prostatic fluid had no effect on a normal seminal fluid.

Case 5.—H. O., aged 30; married eight years. Nothing relevant in the history, and physical examination normal. Asthenospermia was present, and spermatolysis was complete in two hours.

Study of these cases suggests that two abnormal spermatozoon types were concerned. In the first type, as exemplified by Cases 3, 4, and 5, oligospermia and hypokinesia were present. Can it be assumed that the factors causing this also caused the spermatolysis? In the second type, as in Cases 1 and 2, the only abnormal feature was the spermatolysis. In all cases it seems right to assume that the spermatolysis was the cause of the sterility, since any sperm undergoing lysis within four to six hours of ejaculation is not likely to fertilize an ovum.

If spermatolysis occurs, then it seems reasonable to suggest that there must be a spermatolysin. In Cases 1 and 2 the only abnormality was spermatolysis, yet prostatic fluid from them caused lysis in the seminal fluid of normal controls. I have concluded that the prostatic secretion of these men contained a "spermatolysin" substance. The epididymis, vas deferens, seminal vesicle, and prostate produce a secretion which nourishes the sperms. Changes in the nature of the trophic products, the result of infection or from unknown causes, can give rise to abnormalities of the spermatozoa—e.g., asthenospermia—but I believe that the actual lysin factor is an abnormal prostatic substance.

Summary

Some cases of sterility in the male are due to agglutination and dissolution of the spermatozoa within a short time of ejaculation. This is spermatolysis.

Spermatolysis was thought to be the cause of sterility in five of 75 cases investigated. In two of these five no abnormality of the sperms apart from lysis was present.

The importance of examining seminal fluid at intervals is stressed. Otherwise if only one examination is done, and that too early, the phenomenon of spermatolysis might not be recognized.

Spermatolysins may be associated with otherwise normal spermatozoa or with abnormal sperm types. In the latter case it may be that a lysin factor is produced in the epididymis, vas deferens, or seminal vesicle, as well as in the prostate.

Medical Memorandum

A Case of Diabetic Coma Treated with 56,000 Units of Insulin

The following notes concern a case of diabetic coma treated at the General Hospital, Jersey. Their interest lies in the dose of insulin given and the conclusions they suggest concerning the use of glucose in diabetic coma.

CASE HISTORY

The patient, a man aged 32, a known diabetic, had previously kept well on a dose of 26 units of P-Z insulin and 16 units of soluble insulin. On Nov. 1, 1948, he had a cold; the following day he felt worse and omitted his insulin and took no food.

At 3 a.m. on Nov. 3 he was admitted to hospital in diabetic coma. Dehydration, air hunger, and the smell of acetone were conspicuous. The urine was "brick red" to Benedict's test and laden with acetone. The temperature was 98.6° F. (37° C.), pulse 102, and respirations 24. Gastric aspiration resulted in about 4 pints (2.28 litres) of dark-brown fluid. 130 units of insulin were given, and an intravenous drip of 5% glucose and 0.5% saline was set up. The blood sugar (B.S.) on admission was 500 mg. per 100 ml. Between 7 a.m. and 4 p.m. 950 units of insulin were given. At 6 p.m. the B.S. was 450 mg. per 100 ml. The pulse had risen to 130 and the patient's condition was worse.

In view of the inefficacy of the above method of treatment it was decided to change to that advocated by Professor Micks. As will be apparent, the inadequate treatment hitherto had permitted a marked state of insulin resistance to occur. At 7 p.m. the glucose drip was replaced with saline. A dose of 500 units of insulin was given and thrice repeated. The B.S. fell to 280 mg. 10,000 units were given at 1.30 a.m.: B.S. 270 mg. At 2.30 a.m. the B.S. had risen to 280 mg. and the patient had collapsed, the pulse being barely perceptible. At the suggestion of the laboratory technician the drip was investigated and was found to have been replenished in error with 5% glucose about an hour previously. The error was remedied and the patient improved.

At 3.15 a.m. 20,000 units of insulin, occupying 250 ml., were injected into several muscle masses, and 400 units into the drip tubing. At 4 a.m. the B.S. was still 280 mg. A second dose of 20,000 units was given and, since soluble insulin was running short 400 units of P.Z.I. This proved to be the final dose. In 26 hours 56,080 units of insulin had been given.

Hitherto the urine (tested hourly) had been continuously "red" to Benedict's test and "acetone + + +." Now at last it began to become concentrated, and sugar and acetone to diminish. It did not become free from sugar and acetone till 22 hours after the last dose of insulin. The B.S. at 8.30 a.m., four hours after the last dose, was 65 mg., the pulse rate 160; the latter thereafter fell steadily and 24 hours later it was 90. No sudden change in the patient reflected the fall in blood sugar. Following the 8.30 a.m. B.S. result, glucose in amounts varying from 5 to 15 g. in 25% solution was administered hourly by drip tubing.

At 5 a.m. on Nov. 5, 25 hours after the last dose of insulin, a hypoglycaemic convulsion occurred without warning. It responded instantaneously to intravenous glucose. Shortly after this the drip was changed to glucose. By evening on the same day the patient was restored to consciousness sufficiently to take additional glucose by mouth. By about 11 p.m., some 65 hours after admission and 4½ hours after the last dose of insulin, he was perfectly *compos mentis*. The drip was discontinued next day, and the patient was nursed flat for three days as a precaution against sudden circulatory failure. He progressed steadily and was discharged on Nov. 25, feeling perfectly fit, on a morning dose of 40 units of P.Z. and 60 units of soluble insulin.

COMMENT

It is to be supposed that the patient's descent into coma was initiated by the cold he had on Nov. 1. No trace of this or evidence of any other infection was apparent on admission. I had expected the conversion of the B.S. from high to low values to be indicated by marked clinical change. A sharp rise in the pulse rate coincided with the event, but this was the only prominent point. The pulse rate and the urinary sugar and acetone gradually diminished, and the patient's general condition slowly improved. Even the hypoglycaemic convulsion, arriving late and without warning and immediately controlled, did not seem to interrupt this steady progress.

B.S. recordings during this period may be of interest. These were: 5 hours after the last dose of insulin, 65 mg. per 100 ml. 7 hours after last dose, 56 mg.; 8 hours, 50 mg. (here the drip was changed to glucose); 10 hours, 62 mg.; 12 hours, 30 mg.; 14 hours, 50 mg.; 16 hours, 24 mg. (no clinical reflection of this low value); 27 hours, 70 mg. (convulsion two hours before this); 29 hours, 60 mg.; 32 hours, 45 mg.; 34 hours, 168 mg.

The lack of response to treatment when glucose was used, the collapse that occurred when it was added in error to the saline drip, and the recuperation that followed the correction of the error, strongly suggest that glucose is not an innocuous substance in diabetic coma and that its use as a precaution against hypoglycaemia may gravely jeopardize the patient's chances of survival. This was emphasized by Root (1945) and Mick (1948).

Gastric aspiration on admission produced brown fluid containing altered blood. A second aspiration twelve hours later yielded about 1 oz. (28 ml.) of blackish fluid, presumably also blood further altered. This, I believe, is a usual occurrence in diabetic coma. I should be interested to know the cause and origin of this blood. I understand that a surgeon operating on a case of chronic pyloric stenosis may occasionally observe blood oozing from the gastric mucous membrane.

I wish to thank Dr. Graeme Bentlif, senior physician to the General Hospital, for permission to publish these notes.

FEMALE REPRODUCTIVE TRACT

The Epithelia of Woman's Reproductive Organs By George N. Papanicolaou, M.D., Ph.D., Herbert F. Traut, M.D., and Andrew A. Marchetti, M.D. (Pp. 53, 22 Plates 55s.) New York: The Commonwealth Fund; London: Geoffrey Cumberlege 1948

Most of this monograph is on the cytological appearances of the normal epithelia of the female reproductive tract. Dr. Papanicolaou is world famous for his studies in this field and his present collaborators have been associated with him in much of his work. The monograph is a triumph of trans-continental collaboration since almost half-way through the ten years devoted to collecting material Dr. Traut left Cornell University to become professor of obstetrics and gynaecology in the University of California.

Discussion of all the normal epithelia from the ovary to the vagina occupies 48 pages. Every one of them is packed with detailed information not only on the cytology of the tissues but on the correlation of the changes which take place throughout the female genital tract as a whole at the different phases of the menstrual cycle and in the menopausal woman. It is clearly shown that all the epithelia take part in these cyclical changes and that the changes in the Fallopian tubes, cervix, and vagina though less well known than those in the ovaries and endometrium are nevertheless completely characteristic to the eye of the expert cytologist. The illustrations are beautifully produced and lend the highest distinction to the work as a whole. Most are in colour, they consist of photomicrographs of admirable clarity and excellent drawings by Hashime Murayama. No doubt the high quality of the production is reflected in the price, though it is difficult to produce work of this kind, which depends so largely on accurate illustration on a less lavish scale.

This monograph will prove an admirable companion to that published five years ago by Dr. Papanicolaou and Dr. Traut on the diagnosis of uterine cancer by the vaginal smear. Their pioneer work in this field is too well known to need further comment, but anyone who wishes to learn this difficult but fascinating method of gynaecological investigation will find these two monographs indispensable. There is no doubt that the vaginal smear will very soon be universally recognized as a routine procedure in gynaecology.

The absence of an index is to be regretted, especially in a work where so many cross references are to be found. The chart given at the end of the book, however, affords an admirable summary of the changes in the menstrual cycle to be seen not only in the epithelia but in the basal-temperature chart and the hormone excretion levels. It also serves to emphasize again the main theme which is that of correlation of cytological changes with function.

JOSEPHINE BARNES

ATLAS OF ANATOMY

Living Anatomy: A Photographic Atlas of Muscles in Action and Surface Contours By R. D. Lockhart, M.D., Ch.M. (Pp. 71; 149 figures 12s. 6d.) London: Faber and Faber 1948

This is a photographic album of "the muscles in action and surface contours" by the staff and students of the anatomy department at Aberdeen. It consists of about 150 photographs, mainly of the superficially placed muscles of the trunk and limbs in different subjects of both sexes. The brief introduction and the photographs will succeed in diverting the attention of the student from the textbook description and the dissecting-room appearance of the muscles. The photographs are instructive, though some criticism may be made of many of the poses in that the subject is shown performing somewhat unusual actions against the resistance of the restraining hands of the master of ceremonies.

The most superficial of all muscles, and among the first to be developed in the embryo, is the platysma. This muscle is not figured. In its extreme contraction its longest fibres are capable

of moving the nipple over one to two rib spaces in the male and even more in the female. Putting this muscle into violent contraction is often of use in examining the female breast for the site, size, shape, consistency, and attachments of a tumour. From the purely artistic point of view there is nothing to approach Paul Richer's *Anatomie Artistique*, which is the best delineation and description of the external form of the muscles at rest and in action. It also is the best portrayal of those fat deposits which lend beauty to the female form.

This album has certainly instructed and entertained the students of Aberdeen. It may stimulate others to the point of reading Duchenne and Beevor, who are gratefully mentioned in the preface.

H. A. HARRIS

EPILEPSY

Epilepsy, Psychiatric Aspects of Convulsive Disorders By Paul H. Hoch, M.D., and Robert P. Knight, M.D. Proceedings of the 36th Annual Meeting of the American Psychopathological Association May, 1946 (Pp. 214, illustrated 21s.) London: William Heinemann Medical Books 1948

This volume contains fifteen chapters by different authors, each discussing some facet of the problem—genetics, prevalence and incidence, social implications, psychopathology, diagnosis, EEG, and so on. It records the proceedings of the annual meeting of the American Psychopathological Association in 1946, so that the psychiatric aspects of epilepsy are naturally discussed at greater length than they would be in a balanced monograph on the subject. The divergence of psychiatric opinion on the psychopathology of epilepsy may be illustrated by two statements by different contributors to this book. The first is that epilepsy, like other manifestations in human life, is a way of expression and living through the stresses and strains of life; the second is that the notion that epileptic seizures may be merely an exaggeration created by difficulties of adjustment to life has been abandoned. It is at any rate satisfactory to have both views presented, so that the reader may decide on the evidence provided for him whether the epileptic attack represents an escape from an unbearable situation, a functional disorder of the brain or perhaps a little of both.

As might be expected in a volume of this kind, the contributions vary in quality. The one on the antisocial aspects of epilepsy makes no attempt to deal with the practical problem of criminal responsibility, and in some of the others there is a great deal of theorizing about very little. There are, however, interesting and up-to-date accounts of the application of the Rorschach test to the delineation of the so-called epileptic personality, and of experimentally produced epilepsy in animals. Patton describes sound-induced convulsions in young albino rats with diets lacking in pyridoxin or magnesium. Kopeloff and his colleagues write of a continued epileptic liability in the monkey induced by the application of alumina cream to the cortex; it seems to be independent of the histological character of the lesion, and is of interest in relation to the observed frequency of epilepsy in man in certain cerebral diseases, such as cysticercosis. Jasper, in a brief but lucid review of the EEG, states his reasoned opinion that the terms grand mal and petit mal should be used as of old to describe the clinical manifestations of epilepsy and should not be tied to specific EEG patterns. Diethelm's thoughtful essay on differential diagnosis is of particular value for the clinician. He records the recall or partial recall under hypnosis of post-epileptic amnesias and considers that fugues occurring in psychopaths may be indistinguishable from epileptic attacks. For this chapter alone the book is worth referring to by every serious student of the subject, and he will doubtless find other matter in it which will engage his particular interest.

CHARLES SIMMONDS

FAILURES IN TREATMENT

Failures in Psychiatric Treatment Edited by Paul H. Hoch, M.D. (Pp. 241 54s. 6d.) New York: Grune and Stratton 1948

In this book are collected the papers presented to the annual meeting of the American Psychopathological Association in 1947. The features which must have made the symposium

intestinal obstruction: however, in each case the history and signs differ in many points from those presented by subacute pancreatitis, and the serum-amylase level is within normal limits.

Confusion with Acute Cholecystitis

The condition most likely to give rise to confusion is acute cholecystitis, especially when subacute pancreatitis is associated with pain and tenderness in the right hypochondrium. The differential points to be borne in mind are the incessant retching which accompanies subacute pancreatitis, the tenderness in the costovertebral angles, and the rise in the serum-amylase level. Acute cholecystitis is often associated with a rise in temperature; this is not seen in subacute pancreatitis.

Undoubtedly many cases of subacute pancreatitis are incorrectly diagnosed as acute cholecystitis. Many of these cases are later subjected to an interval operation, and at laparotomy nothing abnormal is found. In such instances cholecystectomy may be performed with minimal pathological justification. On the other hand, evidence of a chronic cholecystitis may be found, and it has been stated that chronic cholecystitis is an aetiological factor in subacute pancreatitis. In such instances it is probably advisable to remove the gall-bladder, but it must be borne in mind that if the original condition was subacute pancreatitis and not acute cholecystitis, then the symptoms are apt to reappear.

Recurrence of symptoms after cholecystectomy is a condition so well known that a name has been given to it—the post-cholecystectomy syndrome. This syndrome may be produced by a stone in the common bile duct or by attacks of pancreatitis. This latter condition, though not generally recognized, is much more frequent than is commonly acknowledged. The following is a typical case.

This patient, aged 67, was admitted to the General Hospital suffering from jaundice. A cholecystectomy was performed in 1930, and since that date the patient had had attacks of pain situated in the epigastrium and left hypochondrium which would continue unabated from two to eight hours. Vomiting and retching and occasionally jaundice were associated with the attacks. During the month before admission the patient had had several such attacks and had become progressively more jaundiced. There was marked glycosuria and the diastatic index of the urine was 6 Wohlgemuth units. Death occurred shortly after admission, and necropsy revealed an enlarged fibrosed pancreas with dilated ducts.

Confusion with Gall-stone Colic

When subacute pancreatitis is associated with jaundice the condition may be confused with gall-stone colic. A careful consideration of the history and physical findings taken in conjunction with the level of the serum amylase would differentiate the two conditions. In this respect the following case of subacute pancreatitis is of interest.

Case 5 (see Table I).—This patient, a young woman, was admitted to the General Hospital on Sept. 19, 1945, with a history of attacks of epigastric pain over the previous ten days, increasing in severity. The pain was constant in nature and was associated with severe vomiting. Four days before admission the patient became jaundiced. On examination she was deeply jaundiced; the abdomen was flaccid, with guarding and tenderness in the right hypochondrium and tenderness in the costovertebral angles posteriorly. A radiograph revealed a shadow in the gall-bladder area which was reported as being possibly due to a gall-stone. The serum amylase was 190 units. A pre-operative diagnosis of cholecystitis was made, but laparotomy revealed a normal gall-bladder with no evidence of calculi. The pancreas was swollen, congested, and oedematous, and the peripancreatic lymph glands were enlarged. The patient made an uneventful recovery. Four weeks later the blood amylase was 80 units.

Treatment

The treatment of subacute pancreatitis is conservative. Rest in bed should be enforced until symptoms have subsided. Large doses of morphine may be necessary in the first few hours to give the patient relief from pain, but apart from this no other special medical treatment is indicated. When there is a history of recurrent attacks of subacute pancreatitis the gall-bladder should be investigated, and if there is any evidence of chronic cholecystitis cholecystectomy should be performed, as it is very probable that the diseased gall-bladder is acting as the focus of infection for the recurrent attacks of pancreatic inflammation.

Typical Case Reports

The following two cases are reported in full as being typical of the conditions described.

Subacute Pancreatitis (Case 6)

A middle-aged man was admitted to the General Hospital on Dec. 28, 1945, complaining of severe pain in the left loin and left hypochondrium. The pain was described as being deep-seated and passing through to the back. It later radiated to the right hypochondrium. The patient vomited at the onset of the attack and had suffered from severe retching throughout.

On examination he was jaundiced and was tender on deep palpation in the left hypochondrium, the epigastrium, the left loin, and the left costovertebral angle. The serum amylase was 439 units and the serum bilirubin 6 mg. per 100 ml. He settled down on conservative treatment, and a month later the blood amylase had fallen to 46 units.

Recurrent Pancreatitis (Case 7)

A man was admitted to the General Hospital on Nov. 2, 1941, complaining of intermittent attacks of epigastric pain over the previous eight weeks. The pain was continuous and was unrelated to food. The attack immediately before admission had continued for four days, during which time he had vomited incessantly. A diagnosis of subacute intestinal obstruction was made. A laparotomy was undertaken, but failed to reveal any abnormality. The patient made an uneventful post-operative recovery.

On Nov. 21, 1942, he was readmitted complaining of an exactly similar attack of only two hours' duration. A diagnosis of perforated gastric ulcer was made, but laparotomy revealed no abnormality in the stomach. The pancreas was swollen greatly and was very hard. He again made an uneventful post-operative recovery.

On May 5, 1944, a similar attack occurred and the patient was readmitted to hospital. A diagnosis of subacute obstruction due to severe constipation was made. It was noticed that he was suffering from severe diabetes.

On April 12, 1946, he was readmitted after an exactly similar attack. On examination he was tender in the epigastrium, the left hypochondrium, and in both costovertebral angles. The blood sugar was 235 mg. per 100 ml. and the blood amylase was 36 units. The patient progressed well on conservative treatment and was discharged in ten days.

I am convinced that Case 7 was a clear-cut instance of recurrent pancreatitis. The low level of the serum amylase is in keeping with the fibrosis which must have occurred in the pancreas.

Conclusion

Subacute pancreatitis has a clinical picture as clear-cut as that presented by a perforated gastric ulcer. The diagnosis, though it may readily be made by consideration of the history and physical signs, is confirmed by the change in the serum-amylase level.

The possibility of subacute pancreatitis must always be borne in mind when diagnosing an abdominal emergency, especially acute cholecystitis. Confusion of the condition with cholecystitis accounts for many of the cases of recurrence of symptoms following cholecystectomy. This error

in diagnosis would largely be obviated if serum-amylase investigations were more often employed in elucidating obscure cases of upper abdominal pain.

Subacute pancreatitis is not a rare condition, and its diagnosis depends largely on being aware of the existence of this clinical syndrome.

Summary

Subacute pancreatitis is a clinical entity readily differentiated from acute haemorrhagic pancreatitis and other abdominal emergencies.

Patients suffering from this condition present as an acute abdominal emergency but settle down on conservative treatment.

The condition is very apt to recur. Of the 19 cases presented 13 were recurrent attacks.

It is suggested that estimation of the serum-amylase level should be more widely employed to differentiate this condition from other acute abdominal lesions.

I would like to thank Professor F. A. R. Stammers for his help in presenting this paper

REPORT ON AN OUTBREAK OF INFLUENZA IN THE ARMY

BY

D. G. MILNE, M.B., Ch.B.
Major, R.A.M.C.

AND

J. D. CRUICKSHANK, M.B., M.R.C.S.
Lieutenant-Colonel, R.A.M.C.

During the months of January and February, 1949, several Army units in Mid-West District, which comprises the whole of Wales and the adjoining English counties, reported that cases of influenza were occurring among their personnel. The first cases to be diagnosed as influenza occurred on Jan. 19 in units stationed at Malvern. The second unit affected was a Boys' Battery of the Royal Artillery, near Rhyl, on Jan. 24. On Jan. 31 cases were reported at Lichfield and on the following day at Donnington. Oswestry garrison were the next victims, on Feb. 7, and by Feb. 21 cases were also being reported from Nesscliffe, near Shrewsbury, Wrexham, and Tonfanau, on the Welsh coast. A total of 646 cases were notified from all Army units in Mid-West District from the start of the outbreak on Jan. 19 to Feb. 21.

Features of the Outbreak

It had been previously impressed upon all ranks that if an epidemic of influenza did occur it was of prime importance to report sick early. Nearly all soldiers affected attended their medical officer within a few hours of experiencing their first symptoms. It is interesting to note that, in one instance only, a soldier remained in his barrack room for over 24 hours before reporting sick. Eighteen out of twenty of his comrades in the same hut developed influenza later.

The main features were a sudden onset with frontal headaches, a transient sore throat without lymph-node enlargement or tenderness, a slight cough, and a feeling of general weakness and lassitude, coupled with aches and pains in the arms and legs and in the lumbar region. Mild rigors preceded the rise in temperature, which was in the neighbourhood of 103° F. (39.4° C.), although a few cases did develop temperatures of 105° F. (40.6° C.). Circumoral pallor, injection of the conjunctivae, and profuse nasal discharge were absent. Epistaxis occurred in a few cases at Lichfield, but was not a common feature. The temperature gradually

dropped, and by the fourth day of the disease most patients were afebrile. Chest complications did not occur and after-effects were absent amongst the great majority of male patients. In the few cases occurring in the W.R.A.C. or A.T.S., however, lassitude and post-influenzal depression were noted.

Patients were treated in camp reception stations until their temperature subsided, and were then transferred to barrack accommodation for a convalescent period of two days before starting duty. The average duration of the illness from the initial symptoms until return to full duty was between six and eight days.

Treatment.—This was of a palliative nature. Warmth, rest in bed, and plenty of fluids by mouth were the main principles adopted. Salicylates and Dover's powder were given during the pyrexial period, and codeine if the cough proved troublesome.

Laboratory Investigations

When it was obvious that a definite outbreak had occurred each garrison was visited and throat washings in 10–15 ml. of sterile saline were taken from selected cases. Febrile patients or cases in the early stages of the illness were chosen so far as was possible. The washings were packed in ice and delivered within six hours to the Central Public Health Laboratory, Colindale, and the National Institute for Medical Research, Hampstead, where they were examined for the presence of virus. Broth was not added to the washings: the addition of 5 ml. would have improved the chances of recovering the virus.

The first of the paired sera required for the Hirst and complement fixation tests was taken at this visit. This was held in the refrigerator at 2–3° C. until the second of the pair was taken, on the twelfth to fourteenth day of the disease.

The sera were examined by Dr. A. P. Goffe at the Central Public Health Laboratory, Colindale; the results are indicated in brief in the tabulated schemes which follow.

TABLE I—Cases at Rhyl (all males)

Case No.	Age in Years	Symptoms					Temperature on Day of Disease
		Shivering	Head-ache	Sore Throat	Cough	Muscle Pains	
1	16½	++	+	+	+	—	100.5° F.: 1st (38.2° C.)
2	15½	++	+	+	+	—	101.6° F.: 1st (38.7° C.)
3	20	++	++	+	+	±	97.0° F.: 3rd (36.1° C.)
4	17½	++	+	—	+	+	98.0° F.: 4th (36.7° C.)
5	16½	—	++	+	+	±	97.8° F.: 3rd (36.5° C.)
6	16	+	++	++	+	—	98.0° F.: 4th (36.7° C.)

Saline Washings.—Report on Feb. 2 1949: Type A virus isolated in two cases from washings taken on Jan. 28, 1949.

Hirst Test.—Four cases showed fourfold rise of antibody inhibiting foal red-cell agglutinin (A PR 8) in second serum. Two cases in which the first serum (taken on the fourth day of illness) showed a high titre (1 in 48) had a twofold rise on the 14th day in antibody to A PR 8 agglutinin.

C.F.T.—Second sera showed 16- to 64-fold rise in complement-fixing antibody to Type A strain antigen.

Result.—Influenza type A.

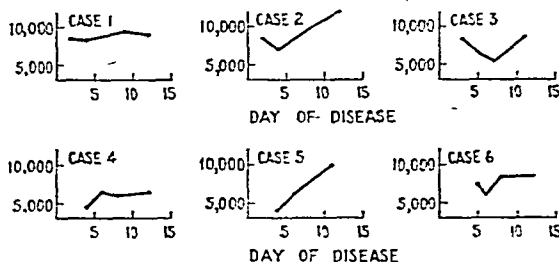

Chart showing the white cell count of the Rhyl cases (see Table I).

TABLE II.—Cases at Lichfield (all males)

Case No.	Symptoms						Temperature on Day of Disease
	Age	Shivering	Head-ache	Sore Throat	Cough	Muscle Pains	
1	18	—	—	Dry	+	—	101.6° F.; 2nd (38.7° C.)
2	18	—	+	Dry	+	+	101.0° F.; 2nd (38.3° C.)
3	19	+	—	Dry	+	—	98.4° F.; 2nd (36.9° C.)
4	22	+	+	+	—	+	102.8° F.; 1st (39.3° C.)

Saline Washings.—Virus was not isolated from these washings.
C.F.T.—Second sera showed 4- or 8-fold rise in titre of complement-fixing antibody to Type A strain antigen.
Result.—Influenza type A.

TABLE III.—Cases at Donnington (all males)

Case No.	Symptoms						Temperature on Day of Disease
	Age	Shivering	Head-ache	Sore Throat	Cough	Muscle Pains	
1	19	+	+	—	—	+	99.6° F.; 3rd (37.55° C.)
2	18	+	+	—	—	+	99.8° F.; 3rd (37.7° C.)
3	18	+	+	—	—	+	98.0° F.; 3rd (36.7° C.)
4	19	+	+	—	—	+	100.0° F.; 2nd (37.8° C.)
5	20	—	+	—	+	+	100.2° F.; 3rd (37.9° C.)
6	19	+	+	—	+	—	100.8° F.; 3rd (38.2° C.)
7	20	+	—	+	+	—	100.2° F.; 5th (37.9° C.)
8	18	+	+	—	+	—	99.4° F.; 3rd (37.4° C.)

Saline Washings.—Type A strain of virus isolated in one case from washings taken on Feb. 9, 1949.
C.F.T.—Second sera showed 8- to 32-fold rise in titre of complement-fixing antibody to Type A strain antigen.
Result.—Influenza type A.

Complement fixation tests on sera from four cases at Malvern showed results with Type A strain antigens similar to those in the Tables.

Preventive Measures

Early diagnosis and rapid isolation of the patient were aimed at in order to check the spread throughout each unit. Strict attention was paid to the adequate ventilation of barrack rooms and to the spacing of beds to the optimum. General measures on the maintenance of the health of the troops, the shaking and airing of blankets in the open, and the sweeping of floors, previously sprinkled with water, were adopted. Routine gargling and the spraying of rooms with disinfectant were not carried out, nor was prophylactic inoculation attempted. Unit cinemas were closed for a short time in two areas at the height of the outbreak, but the numbers of cases occurring did not warrant restricting movement of troops or cancelling the intake of National Service men to training establishments.

The movements of the first three cases occurring in each unit prior to the onset of symptoms were investigated, with, however, inconclusive results. No direct connexion with the European epidemic could be traced.

Summary

An outbreak of influenza of the Virus A type occurring in Army units in Wales and the West Midlands is reported. Symptoms, treatment, laboratory investigations, and preventive measures adopted are described.

Our thanks are due to Lieutenant-General Neil Cantlie, C.B., M.C., K.H.P., Director-General Army Medical Services, and Major-General R. W. Galloway, C.B., C.B.E., D.S.O., K.H.S., D.D.M.S. Western Command, for permission to publish this report.

SPONTANEOUS INTRA-ABDOMINAL HAEMORRHAGE

BY

A. L. WOOLF, M.B., B.S.

AND

H. R. THOMSON, M.D., M.R.C.P.

(From the Central Middlesex County Hospital,
Park Royal, London)

Spontaneous intraperitoneal haemorrhage—i.e., that occurring without any obvious cause such as cirrhosis of the liver (James, 1930) and rupture of aneurysm—has been recorded in 26 cases*—19 collected by Berk, Rothschild, and Doanet (1941), three reported by Marks and Freedlander (1945), and one each by Keusenhoff (1934), Matheson (1934), Crile and Newell (1940), and Haugen (1944).

In only eight of these cases were necropsies performed. In Keusenhoff's case and in two cases recorded by Moorehead and McLester (1936) a definite arterial rupture was found: but in the remaining five no single vessel could be held responsible, though in Matheson's case the haematoma was related to the branches of the ileocolic artery. Four of the cases had clinical or morbid anatomical evidence of hypertension (Moorehead and McLester two, and the fatal case of Marks and Freedlander) or arteriosclerosis (Keusenhoff). Haugen's case, which followed appendicectomy, like those of Matheson (1934), Churchman (1911) and Hartley and MacKechnie (1934), showed no evidence of vascular disease, but in these cases blood-pressure readings before the catastrophe or reports on the histology of the kidneys are lacking.

Three cases of spontaneous abdominal haemorrhage, two of which included a haemoperitoneum, are described below.

Case 1

A woman aged 58 was admitted with a four-months history of discharging ear (? cerebral abscess). She had had pain in the left hypochondrium for one month accompanied by vomiting when severe. Investigations before admission showed: haemoglobin, 66%; leucocytes, 17,300 per c.mm. (89% neutrophils); serum Wassermann reaction, negative.

On examination the temperature was 99° F. (37.2° C.), pulse 110. She had a profuse discharge from the right ear, and diplopia on looking above the horizontal. The abdomen appeared normal. The B.P. was 140/80. Leucocytes numbered 43,000 per c.mm. Two days after admission she had severe upper abdominal pain and urge to defaecate, but the bowels were not opened. On examination she was pale, the pulse was 160, and there was extreme tenderness in the upper half of the abdomen. She died in less than an hour.

Necropsy.—Intracranial disease was not discovered. Very marked purulent bronchitis and emphysema were found. On opening the abdomen large blood clots were seen in the peritoneal cavity. The greater omentum and lesser sac also contained blood clot. Careful dissection of the branches of the coeliac axis, the superior mesenteric artery, and the tributaries of the portal vein failed to reveal any macroscopic evidence of structural change in their walls or of thrombosis. Smaller vessels within the area of haemorrhage in the pancreas were also minutely examined without any abnormality being detected. Both renal arteries contained thrombi, the kidneys appearing very pale but otherwise normal. The bowel contents were black, but there was no macroscopic lesion in the intestinal mucosa.

Histology.—Omentum:—A huge area of haemorrhage occupied the omental fat tissue, which included a central area of

*Since submission of this paper a case of malignant hypertension with haemoperitoneum has been published by De Navasquez and French.

†The case of Florence and Ducuing (1913) was traumatic.

haemorrhagic necrosis. This area was surrounded by macrophages containing haemosiderin. Outside the haemorrhagic areas the arterioles showed fibrinoid thickening of the intima, and collars of lymphocytes, eosinophils, and macrophages. In addition, several islets of haemopoiesis were found. *Myocardium*.—Only the vascular changes were striking. The arterioles showed subintimal swelling, sometimes in the form of appositional loosely woven pink cushions and sometimes in the form of intensely eosinophil hillocks over which endothelial cells appeared unusually prominent and sometimes detached. *Spleen*.—There was very extensive and marked hyaline fibrinoid infiltration of walls of arterioles with reduplication of elastic laminae of some vessels. *Pancreas*.—Marked hyalinosis of arterioles was present. Stroma was rich in fat grapes and contained extensive areas of haemorrhage. *Stomach*.—Arterioles of outer layers of wall, outside and in the periphery of blood clot, showed marked hyaline fibrinoid infiltration. Innumerable collagen shreds could be seen in the clot. *Kidney*.—A fair number of glomeruli showed hyalinosis of the afferent arterioles. Many glomeruli appeared enlarged, with fusion and hyalinization of loops and increase in nuclei. There were tubular casts but no crescent formation. An occasional glomerulus showed fibrinoid change in some of its loops. Another section showed several collections of lymphocytes, the most conspicuous being around a hyalinized vessel the lumen of which was completely occluded by hyaline material, part of which showed fibrinoid change.

Comment.—Necropsy revealed no intracranial lesion and no source for the haemorrhage. Histologically there were widespread arteriolar thickening and kidney changes, as normally seen in hypertension, to which the massive intraperitoneal haemorrhage may therefore be attributed, in spite of the readings, which were, however, taken only after the onset of the disease. That the arteriolar changes may have given rise to the haemorrhage is possible, especially as similar lesions occurring in dermatomyositis have been shown (Pagel, Woolf, and Asher, 1948) to lead to extravasation of blood, though this was admittedly microscopic. Goldblatt's (1938) finding of petechial and larger haemorrhages in dogs with experimental malignant hypertension provides further support. The petechial haemorrhages in such cases were associated with dissection of necrotic or hyalinized arteriolar walls by red blood corpuscles. On the other hand, the possibility of a haemorrhagic diathesis may be considered, although Bruce's (quoted by Berk, Rothschild, and Doane, 1941) similar case with recovery was subsequently investigated for bleeding tendency without success. Multiple small discrete haematomata in the greater omentum and mesentery in Hartley and MacKechnie's case, however, suggest that their patient may have had a haemorrhagic diathesis.

The following case of abdominal haemorrhage affecting chiefly the ilio-psoas muscle, though lacking a haemoperitoneum, showed in other respects a striking resemblance to Case 1, and is therefore included.

Case 2

A woman aged 65 had had rheumatoid arthritis for eight years, and recently the onset of dyspnoea, nycturia, and swelling of the feet. On examination myxoedema, congestive cardiac failure, and advanced rheumatoid arthritis were found. The B.P. was 180/100. She collapsed and died two days after admission.

Necropsy.—Very pale and thin body. Basilar artery and circle of Willis showed severe atheroma. Right pleura adherent and oedematous, with numerous small haemorrhages (up to 0.4 cm. diameter), marked left ventricular hypertrophy, and atheroma of endocardium below aortic valves. Severe atheroma of coronary arteries. Femoral arteries showed medial sclerosis. Kidneys granular, with variegated cortex. There were extensive areas of intramuscular haemorrhage up to 5 by 4 cm. diameter in the superficial portions of the rectus abdominis and in the ilio-psoas muscles.

Histology.—*Psoas muscle*.—There was a massive haemorrhage beneath the fascia but no appreciable haemorrhage in the muscle itself. In addition to the extensions of the extravasation along the interfascicular stroma there were striking cellular and muscular changes. (a) *The cellular changes* consisted of dense perivascular and interstitial infiltration with plasma cells and lymphocytes, the former being predominant around the vessels, which, though for the most part appearing normal or showing slight fibrous thickening, occasionally showed intensely eosinophil eccentric intimal cushions as described in the myocardium in Case 1. (b) *The muscular changes* occurred only between the strata of extravasated blood, and consisted of vacuolation and shrinking of sarcoplasm with evidence of cellular regeneration. *Heart muscle*.—Conspicuous eccentric subintimal cushion formation in small arterioles. *Kidney*.—Extreme glomerular hyalinization of the wire-loop type, many glomeruli being completely atresic. There was also atrophy of the renal tubules.

Comment.—The presence of severe arteriolar disease and the clinically observed hypertension suggest a primarily vascular cause for the haemorrhages in this case. This is corroborated by the confinement of the pictures of muscular degeneration to the haemorrhagic areas. The perivascular, lymphocytic, and plasma-cell cuffing in the area of haemorrhage in these two cases is probably a local reaction to the latter, and is described in cases of perirenal haematoma by Heilmann (1930).

Case 3

A man aged 63 was admitted two hours after an acute onset of pain in the right hypochondrium radiating to the right scapular angle. The pain was dull and continuous, and he felt as though blown up with wind. There was slight nausea but no vomiting. A similar attack a year previously, diagnosed as a coronary thrombosis, cleared up after a week in bed.

On examination he was seen to be obese and pale, and he was sweating. The pulse was 72, temperature 97° F. (36.1° C.), and respirations 20. The blood pressure was 220/125. The abdomen was distended and tympanitic, without shifting dullness. There was tenderness but no rigidity in all areas, most pronounced in the right upper quadrant and extending round the flank to the right loin. Peristalsis was diminished. Rectal examination showed no abnormality and the urine was normal. On two occasions after admission he suddenly became shocked and his blood pressure fell to 60/40 but with a pulse rate of only 80. On each occasion he recovered in a few hours. On the afternoon following admission the tenderness and the gnawing pain were localized to the right iliac fossa. Laparotomy was performed for "acute appendicitis." There was much free blood in the peritoneal cavity and adhesions were present, mainly on the right side. In the right iliac fossa a fresh retroperitoneal haematoma was spreading towards the right loin, and a large boggy swelling was palpated in the position of the right kidney. Death occurred 30 hours after operation.

Necropsy.—Short, fat man. Right pararectal operation wound. *Heart*.—Weight, 800 g.; left ventricular hypertrophy. *Aorta*.—Gross atheroma. Peritoneum contained 60 oz. (1.7 litres) of fresh blood; omentum adherent to anterior abdominal wall. *Intestines*.—Gross distension; coil of terminal ileum adherent to pelvic peritoneum and obstructed by an omental band. Adhesions between gall-bladder and transverse colon. There was a large blood clot in the right perirenal fat which extended to the splenic flexure. The right suprarenal gland was expanded by a dense blood clot; external measurements 7 by 3 by 3 cm. The right kidney was surrounded by blood clot but was normal, apart from autolysis, and its capsule was intact. The renal artery was free from thrombosis, but the suprarenal artery could not be identified owing to the advanced autolysis.

Histology.—Suprarenal gland.—wholesale necrosis of the cortex, also of the capsular fat tissue. Some islets of parenchyma were still preserved in the central areas, where there was fibrinoid infiltration of the septa. With staining for elastic tissue the outlines of vein walls were visible in the centre of the blood clot.

Comment.—Perirenal haematoma was first described by Wunderlich (1856) under the title of "Apoplexie des

Nierenlagers," and was later classified into four categories by Ponfick (quoted by Coenen, 1910). Case 3 is an example of Ponfick's haematoma renis extracapsulare. Coenen, who collected 12 cases of perirenal haematoma and reported one of his own, mentions nephritis, renal sarcoma, arteriosclerosis, renal tuberculosis, chronic splenomegaly with gastritis, and haemophilia as the associated conditions. Heilmann (1930), who reported four cases of perirenal haematoma, suggests spasm of the capsular vessels as an aetiological factor. Cases of gross suprarenal haemorrhage have been reported in adults (Keele and Keele, 1942; Burnett, 1948). Eleven cases had previously been described. Only three of these cases, including those of Keele and Keele, were unilateral, as was the case under discussion, and in no instance was there a haemoperitoneum. In addition to atheroma and a possible spastic mechanism owing to hypertension, thrombosis of the suprarenal vein as in Keele and Keele's case should be considered as the proximate cause.

Summary

Three cases of intra-abdominal haemorrhage are reported. All three had evidence of hypertension.

The first case was one of spontaneous intraperitoneal haemorrhage with no morbid anatomical source for the bleeding apart from hypertensive changes in the smaller vessels.

The second case showed intramuscular haematoma; hypertensive arteriolar disease was sufficient to account for the haemorrhage.

The third case showed a haemoperitoneum from rupture of a perirenal haematoma. The origin of this is discussed. There was clinical evidence of severe hypertension.

Our thanks are due to Dr. W. Pagel for provision of material and assistance in preparation of this paper, to Dr. R. J. Porter, Dr. R. A. J. Asher, and Mr. J. D. Fergusson for the use of the clinical notes, and to Mr. L. Spain for histological assistance.

The British Council for the Welfare of Spastics has produced an admirable pamphlet entitled "Notes for Parents on the Home Care of Children Handicapped by Cerebral Palsy." It has been prepared by Dr. J. H. Crosland, of the Physical Medicine Department, Caring Cross Hospital, and Mr. H. P. Weston, executive secretary of the council. After a short account of the causes and nature of cerebral palsy the authors describe in detail how to care for spastic and athetoid children, while emphasizing that they must not be coddled. While these children must receive what help they need, the parents' natural anxiety should not prompt them to make their children over-dependent. Self-confidence and a sense of security must be inculcated into the children, and there are illustrations of special furniture, toys, and feeding utensils that will help the children to live as independently as possible. Special sections are included on the training of speech and excretion. Particulars may be obtained from the council's honorary executive secretary at 107, Norfolk Avenue, Sanderstead, Surrey. The pamphlet is obtainable from the same address for 1s. 3d. post free.

EFFECT OF PRESSURE COOKING ON VITAMIN C CONTENT OF VEGETABLES

BY

GWENETH M. CHAPPELL, M.Sc.

AND

AUDREY M. HAMILTON, B.Sc.

(From King's College of Household and Social Science, University of London)

We have recently been investigating the effect of pressure cooking upon the loss of vitamin C in vegetables. As it may be some time before we can continue this work, and as there is considerable topical interest in the question, the results so far obtained are here briefly reported.

Method

In order that the results may be interpreted readily, we have compared the effects of pressure cooking with those of cooking in an ordinary saucepan. Since it is known that factors such as the volume of water and the period of cooking greatly affect the loss of vitamin C in the saucepan, the method adopted was that known to conserve the vitamin as much as possible. This method, advocated by the Ministry of Food, involves the use of a small volume of water, bringing this to the boil before putting in the vegetable, and cooking for the minimal time. With one exception, 200 g. of vegetable was cooked in 200 ml. of water in the saucepan, as this was found to be the minimal amount of liquid necessary to prevent the saucepan boiling dry. The exception was spinach, to which, as in common practice, water was not added.

The pressure cooker used was one of the now popular variety with a capacity of 7 pints (3.96 litres). The vegetables were cooked in this according to the directions supplied by the manufacturer. Again 200 g. of vegetables was used, but only 100 ml. of water. A larger volume of water is unnecessary, and would undoubtedly result in a greater loss of vitamin C by leaching. Care was taken to avoid overcooking with either method.

In every experiment six samples of each raw vegetable, so far as possible equivalent and representative, were taken. Two were for the determination of the initial content of vitamin C, two for the pressure cooking, and two for saucepan cooking. Two different portions of each raw sample of vegetable and three of each cooked sample were taken for analysis. The vitamin C was also assayed in the cooking-water. Thus for every experiment 20 samples were assayed, each assay being made in duplicate. In all, 14 experiments were performed on 10 different vegetables. The method of estimation used was that of Harris and Olliver (1942).

Results

In view of the varying nature of different vegetables and of different specimens of the same type, it was not to be expected that the variation in results between the two methods of cooking would be uniform. In all of the 10 vegetables examined there was no evidence that saucepan cooking was better than pressure cooking in retaining vitamin C. In six vegetables—cauliflower, broccoli, winter cabbage, new carrots, turnips, and swedes—the retention was consistently better in pressure cooking by between 3 and 28% of the original amount of vitamin C. In the other four vegetables—spring cabbage, broad beans, old carrots, and spinach—pressure cooking gave a slightly higher retention in some experiments and a slightly lower retention in others. The average difference in

these instances was always small—of the order of 5% in favour of the one or the other method. The average retention of the original vitamin C in all the experiments performed was 7.5% more in pressure cooking than in saucepan cooking—66% against 58.5%.

The estimations of vitamin C in the cooking-water showed that, with the exception of spinach, there was a greater loss by leaching in the saucepan than in the pressure pan. The results with spinach were no doubt due to the fact that no water was added to the saucepan, whereas 100 ml. was added in the pressure cooker. It is often recommended that the water used in cooking vegetables should be used in soups, stews, and gravies. This is, however, not often done, and when it is the liquid is frequently kept for some time and then cooked again. If it were to be used immediately the difference in the total ascorbic acid in the vegetable and cooking-water together would be negligible when comparing the two methods of cooking. In other words, the total amount of the vitamin in the vegetable and cooking-water together was on the average almost the same in the two forms of cooking (78% pressure cooking; 79.6% saucepan cooking).

Discussion

This investigation is of necessity limited by difficulties peculiar to any attempt to bring laboratory methods to domestic problems. On the one hand, it is clearly necessary to control as many factors as possible by using standardized conditions; on the other hand, it is obvious that no two housewives will cook in identical conditions; in fact, these conditions will differ from time to time even in one kitchen.

In the controlled conditions we have used it is evident that, so far as the retention of vitamin C is concerned, pressure cooking is certainly no worse than cooking in a saucepan, and in some instances is better. The differences are small, however, so that a bad technique with either method would result in a greater loss of the vitamin with that method. In some of our work, overcooking in the pressure cooker or a longer time in reaching the necessary pressure led to an appreciably greater loss of vitamin. Again, in what is still, unfortunately, the common way of cooking vegetables in a saucepan, with large volumes of water and a tendency to overcook, there is a greater loss of vitamin C than in the Ministry of Food method used in these experiments. It is probable, therefore, that either type of cooking in the home will often cause greater loss of vitamin C than in our experiments. This is more likely to occur when the saucepan is used: overcooking of vegetables in the pressure cooker results so easily in disintegration that housewives soon learn to avoid this, whereas slight overcooking with a large volume of water in the saucepan results in no obvious loss in appearance or palatability. We may reasonably conclude that, in general, the retention of vitamin C in vegetables in pressure cooking is likely to be no worse, and will probably be better, than in the saucepan when either process is used in the home. There is certainly no reason, from our experiments, to suppose that pressure cooking should be discouraged because of its effect upon the nutritive value of vegetables.

So far as other foods and vitamins are concerned, very little has been published. A few experiments of our own on the vitamin B₁ content of pulses suggest that the pressure cooker is better than the saucepan.

Summary

A comparison has been made of the effect upon the retention of vitamin C in 10 different vegetables when cooked in a modern pressure saucepan and in an ordinary saucepan according to the recommended methods. On the average the

retention was higher in vegetables cooked in the pressure cooker.

We should like to thank Professor John Yudkin for his counsel, and the Ministry of Food for cooking some of the samples.

SPERMATOLYSIS: A CAUSE OF MALE STERILITY

BY

CAFER YILDIRAN, M.D.

Urological Surgeon, Trabzon-Numune Hospital; member of Turkish Medical Society; British Council Student in Urology

Much attention has been directed of late towards the problem of sterility and infertility. In consequence I have been stimulated to present the results of some studies on male sterility which suggest a causative factor not hitherto described.

During the investigation of 75 males complaining of sterility at the urological clinic of Dr. A. E. Gussel, in the Guraba Hospital, Istanbul, I came across two specific abnormal spermatozoon types which were thought to be the cause of the sterility. The purpose of this communication is to call attention to the abnormalities. Short summaries of five of the case histories are given.

Case Reports

Case 1.—H.T., married five years; no children; wife pronounced normal by the gynaecologist. No history of venereal disease. No physical abnormality present. Examination of sperm 30 minutes after collection showed no microscopical or macroscopic abnormality. After two hours the specimen was separating into two layers—a clear supernatant and a sedimented layer. Microscopically the clear layer was acellular, but the sediment contained aggregations of dying spermatozoa. (I intend to make some observations on the death of spermatozoa in a further paper.) As time passed fewer and fewer sperms were seen, until at the end of six hours none were visible—the phenomenon of spermatolysis. Furthermore, the fluid obtained from this patient by prostatic massage caused spermatolysis to occur in the semen of a normal control when added to the latter.

Case 2.—N.O., married four times in the previous twenty years. One of his former wives had remarried and had had a family. No previous venereal disease, and no abnormal physical findings. The seminal fluid appeared to be more viscous than normal, but microscopically it seemed normal in every way up to two hours, when agglutination was beginning. After six hours spermatolysis was complete as in Case 1, and again prostatic fluid from this case caused spermatolysis when added to a normal control seminal fluid.

Case 3.—H.D., aged 34; married eight years; no history of venereal disease; wife normal. A spermogram showed oligospermia and hypokinesia. In two hours spermatolysis was complete.

In these three cases aspiration of the epididymis was performed. Unfortunately no sperms were found in any of the specimens, but in Case 3 minute comma-shaped bodies about 2 by 4 μ were seen. They showed some brownian movement. I got the impression that they were microsperms. Within two hours they had undergone lysis. In normal cases spermatozoa aspirated from the epididymis live two to three days.

Case 4.—F.O., aged 32; married three years; history of gonorrhoea twice, with clinical cure; no evidence of epididymitis or prostatitis; wife normal. Semen appeared normal

but showed asthenospermia microscopically. In five hours spermatolysis was complete, but in this case the prostatic fluid had no effect on a normal seminal fluid.

Case 5.—H. O., aged 30; married eight years. Nothing relevant in the history, and physical examination normal. Asthenospermia was present, and spermatolysis was complete in two hours.

Study of these cases suggests that two abnormal spermatozoon types were concerned. In the first type, as exemplified by Cases 3, 4, and 5, oligospermia and hypokinesia were present. Can it be assumed that the factors causing this also caused the spermatolysis? In the second type, as in Cases 1 and 2, the only abnormal feature was the spermatolysis. In all cases it seems right to assume that the spermatolysis was the cause of the sterility, since any sperm undergoing lysis within four to six hours of ejaculation is not likely to fertilize an ovum.

If spermatolysis occurs, then it seems reasonable to suggest that there must be a spermatolysin. In Cases 1 and 2 the only abnormality was spermatolysis, yet prostatic fluid from them caused lysis in the seminal fluid of normal controls. I have concluded that the prostatic secretion of these men contained a "spermatolysin" substance. The epididymis, vas deferens, seminal vesicle, and prostate produce a secretion which nourishes the sperms. Changes in the nature of the trophic products, the result of infection or from unknown causes, can give rise to abnormalities of the spermatozoa—e.g., asthenospermia—but I believe that the actual lysis factor is an abnormal prostatic substance.

Summary

Some cases of sterility in the male are due to agglutination and dissolution of the spermatozoa within a short time of ejaculation. This is spermatolysis.

Spermatolysis was thought to be the cause of sterility in five of 75 cases investigated. In two of these five no abnormality of the sperms apart from lysis was present.

The importance of examining seminal fluid at intervals is stressed. Otherwise if only one examination is done, and that too early, the phenomenon of spermatolysis might not be recognized.

Spermatolysins may be associated with otherwise normal spermatozoa or with abnormal sperm types. In the latter case it may be that a lysis factor is produced in the epididymis, vas deferens, or seminal vesicle, as well as in the prostate.

Medical Memorandum

A Case of Diabetic Coma Treated with 56,000 Units of Insulin

The following notes concern a case of diabetic coma treated at the General Hospital, Jersey. Their interest lies in the dose of insulin given and the conclusions they suggest concerning the use of glucose in diabetic coma.

CASE HISTORY

The patient, a man aged 32, a known diabetic, had previously kept well on a dose of 26 units of P-Z insulin and 16 units of soluble insulin. On Nov. 1, 1948, he had a cold; the following day he felt worse and omitted his insulin and took no food.

At 3 a.m. on Nov. 3 he was admitted to hospital in diabetic coma. Dehydration, air hunger, and the smell of acetone were conspicuous. The urine was "brick red" to Benedict's test and laden with acetone. The temperature was 98.6° F. (37° C.), pulse 102, and respirations 24. Gastric aspiration resulted in about 4 pints (2.28 litres) of dark-brown fluid. 130 units of insulin were given, and an intravenous drip of 5% glucose and 0.5% saline was set up. The blood sugar (B.S.) on admission was 500 mg. per 100 ml. Between 7 a.m. and 4 p.m. 950 units of insulin were given. At 6 p.m. the B.S. was 450 mg. per 100 ml. The pulse had risen to 130 and the patient's condition was worse.

In view of the inefficacy of the above method of treatment it was decided to change to that advocated by Professor Micks. As will be apparent, the inadequate treatment hitherto had permitted a marked state of insulin resistance to occur. At 7 p.m. the glucose drip was replaced with saline. A dose of 500 units of insulin was given and thrice repeated. The B.S. fell to 280 mg. 10,000 units were given at 1.30 a.m.: B.S. 270 mg. At 2.30 a.m. the B.S. had risen to 280 mg. and the patient had collapsed, the pulse being barely perceptible. At the suggestion of the laboratory technician the drip was investigated and was found to have been replenished in error with 5% glucose about an hour previously. The error was remedied and the patient improved.

At 3.15 a.m. 20,000 units of insulin, occupying 250 ml., were injected into several muscle masses, and 400 units into the drip tubing. At 4 a.m. the B.S. was still 280 mg. A second dose of 20,000 units was given and, since soluble insulin was running short, 400 units of P.Z.I. This proved to be the final dose. In 26 hours 56,080 units of insulin had been given.

Hitherto the urine (tested hourly) had been continuously "red" to Benedict's test and "acetone + + +". Now at last it began to become concentrated, and sugar and acetone to diminish. It did not become free from sugar and acetone till 22 hours after the last dose of insulin. The B.S. at 8.30 a.m., four hours after the last dose, was 65 mg., the pulse rate 160; the latter thereafter fell steadily and 24 hours later it was 90. No sudden change in the patient reflected the fall in blood sugar. Following the 8.30 a.m. B.S. result, glucose in amounts varying from 5 to 15 g. in 25% solution was administered hourly by drip tubing.

At 5 a.m. on Nov. 5, 25 hours after the last dose of insulin, a hypoglycaemic convulsion occurred without warning. It responded instantaneously to intravenous glucose. Shortly after this the drip was changed to glucose. By evening on the same day the patient was restored to consciousness sufficiently to take additional glucose by mouth. By about 11 p.m., some 65 hours after admission and 43 after the last dose of insulin, he was perfectly *compos mentis*. The drip was discontinued next day, and the patient was nursed flat for three days as a precaution against sudden circulatory failure. He progressed steadily and was discharged on Nov. 25, feeling perfectly fit, on a morning dose of 40 units of P.Z. and 60 units of soluble insulin.

COMMENT

It is to be supposed that the patient's descent into coma was initiated by the cold he had on Nov. 1. No trace of this or evidence of any other infection was apparent on admission. I had expected the conversion of the B.S. from high to low values to be indicated by marked clinical change. A sharp rise in the pulse rate coincided with the event, but this was the only prominent point. The pulse rate and the urinary sugar and acetone gradually diminished, and the patient's general condition slowly improved. Even the hypoglycaemic convulsion, arriving late and without warning and immediately controlled, did not seem to interrupt this steady progress.

B.S. recordings during this period may be of interest. These were: 5 hours after the last dose of insulin, 65 mg. per 100 ml.; 7 hours after last dose, 56 mg.; 8 hours, 50 mg. (here the drip was changed to glucose); 10 hours, 62 mg.; 12 hours, 30 mg.; 14 hours, 50 mg.; 16 hours, 24 mg. (no clinical reflection of this low value); 27 hours, 70 mg. (convulsion two hours before this); 29 hours, 60 mg.; 32 hours, 45 mg.; 34 hours, 168 mg.

The lack of response to treatment when glucose was used, the collapse that occurred when it was added in error to the saline drip, and the recuperation that followed the correction of the error, strongly suggest that glucose is not an innocuous substance in diabetic coma and that its use as a precaution against hypoglycaemia may gravely jeopardize the patient's chances of survival. This was emphasized by Root (1945) and Micks (1948).

Gastric aspiration on admission produced brown fluid containing altered blood. A second aspiration twelve hours later yielded about 1 oz. (28 ml.) of blackish fluid, presumably also blood further altered. This, I believe, is a usual occurrence in diabetic coma. I should be interested to know the cause and origin of this blood. I understand that a surgeon operating a case of chronic pyloric stenosis may occasionally observe blood oozing from the gastric mucous membrane.

I wish to thank Dr. Graeme Bentlif, senior physician to the General Hospital, for permission to publish these notes.

FEMALE REPRODUCTIVE TRACT

The Epithelia of Woman's Reproductive Organs By George N. Papanicolaou, M.D., Ph.D. Herbert F. Traut, M.D., and Andrew A. Marchetti, M.D. (Pp 53, 22 Plates 55s) New York: The Commonwealth Fund London: Geoffrey Cumberlege 1948

Most of this monograph is on the cytological appearances of the normal epithelia of the female reproductive tract. Dr. Papanicolaou is world famous for his studies in this field and his present collaborators have been associated with him in much of his work. The monograph is a triumph of trans-continental collaboration since almost half-way through the ten years devoted to collecting material Dr. Traut left Cornell University to become professor of obstetrics and gynaecology in the University of California.

Discussion of all the normal epithelia from the ovary to the vagina occupies 48 pages. Every one of them is packed with detailed information not only on the cytology of the issues but on the correlation of the changes which take place throughout the female genital tract as a whole at the different phases of the menstrual cycle and in the menopausal woman. It is clearly shown that all the epithelia take part in these cyclical changes and that the changes in the Fallopian tubes, cervix, and vagina though less well known than those in the ovaries and endometrium are nevertheless completely characteristic to the eye of the expert cytologist. The illustrations are beautifully produced and lend the highest distinction to the work as a whole. Most are in colour, they consist of photomicrographs of admirable clarity and excellent drawings by Hashime Murayama. No doubt the high quality of the production is reflected in the price, though it is difficult to produce work of this kind, which depends so largely on accurate illustration on a less lavish scale.

This monograph will prove an admirable companion to that published five years ago by Dr. Papanicolaou and Dr. Traut on the diagnosis of uterine cancer by the vaginal smear. Their pioneer work in this field is too well known to need further comment, but anyone who wishes to learn this difficult but fascinating method of gynaecological investigation will find these two monographs indispensable. There is no doubt that the vaginal smear will very soon be universally recognized as a routine procedure in gynaecology.

The absence of an index is to be regretted, especially in a work where so many cross references are to be found. The chart given at the end of the book, however, affords an admirable summary of the changes in the menstrual cycle to be seen not only in the epithelia but in the basal-temperature chart and the hormone excretion levels. It also serves to emphasize again the main theme which is that of correlation of cytological changes with function.

JOSEPHINE BARNES

ATLAS OF ANATOMY

Living Anatomy: A Photographic Atlas of Muscles in Action and Surface Contours By R. D. Lockhart, M.D., Ch.M. (Pp 71; 149 figures 12s 6d) London: Faber and Faber 1948

This is a photographic album of "the muscles in action and surface contours" by the staff and students of the anatomy department at Aberdeen. It consists of about 150 photographs, mainly of the superficially placed muscles of the trunk and limbs in different subjects of both sexes. The brief introduction and the photographs will succeed in diverting the attention of the student from the textbook description and the dissecting-room appearance of the muscles. The photographs are instructive, though some criticism may be made of many of the poses in that the subject is shown performing somewhat unusual actions against the resistance of the restraining hands of the master of ceremonies.

The most superficial of all muscles, and among the first to be developed in the embryo, is the platysma. This muscle is not figured. In its extreme contraction its longest fibres are capable

of moving the nipple over one to two rib spaces in the male and even more in the female. Putting this muscle into violent contraction is often of use in examining the female breast for the site, size, shape, consistency, and attachments of a tumour. From the purely artistic point of view there is nothing to approach Paul Richer's *Anatomie Artistique*, which is the best delineation and description of the external form of the muscles at rest and in action. It also is the best portrayal of those fat deposits which lend beauty to the female form.

This album has certainly instructed and entertained the students of Aberdeen. It may stimulate others to the point of reading Duchenne and Beevor, who are gratefully mentioned in the preface.

H. A. HARRIS

EPILEPSY

Epilepsy, Psychiatric Aspects of Compulsive Disorders By Paul H. Hoch, M.D., and Robert P. Knight, M.D. Proceedings of the 36th Annual Meeting of the American Psychopathological Association May, 1946 (Pp 214, illustrated 21s) London: William Heinemann Medical Books 1948

This volume contains fifteen chapters by different authors, each discussing some facet of the problem—genetics, prevalence and incidence, social implications, psychopathology, diagnosis, E.E.G., and so on. It records the proceedings of the annual meeting of the American Psychopathological Association in 1946, so that the psychiatric aspects of epilepsy are naturally discussed at greater length than they would be in a balanced monograph on the subject. The divergence of psychiatric opinion on the psychopathology of epilepsy may be illustrated by two statements by different contributors to this book: the first is that epilepsy, like other manifestations in human life, is a way of expression and living through the stresses and strains of life; the second is that the notion that epileptic seizures may be merely an exaggeration created by difficulties of adjustment to life has been abandoned. It is at any rate satisfactory to have both views presented, so that the reader may decide on the evidence provided for him whether the epileptic attack represents an escape from an unbearable situation, a functional disorder of the brain or perhaps a little of both.

As might be expected in a volume of this kind, the contributions vary in quality. The one on the antisocial aspects of epilepsy makes no attempt to deal with the practical problem of criminal responsibility, and in some of the others there is a great deal of theorizing about very little. There are, however, interesting and up-to-date accounts of the application of the Rorschach test to the delineation of the so-called epileptic personality, and of experimentally produced epilepsy in animals. Patton describes sound-induced convulsions in young albino rats with diets lacking in pyridoxin or magnesium. Kopeloff and his colleagues write of a continued epileptic liability in the monkey induced by the application of alumina cream to the cortex; it seems to be independent of the histological character of the lesion, and is of interest in relation to the observed frequency of epilepsy in man in certain cerebral diseases, such as cysticercosis. Jasper, in a brief but lucid review of the E.E.G., states his reasoned opinion that the terms grand mal and petit mal should be used as of old to describe the clinical manifestations of epilepsy and should not be tied to specific E.E.G. patterns. Diethelm's thoughtful essay on differential diagnosis is of particular value for the clinician. He records the recall or partial recall under hypnosis of post-epileptic amnesias and considers that fugues occurring in psychopaths may be indistinguishable from epileptic attacks. For this chapter alone the book is worth referring to by every serious student of the subject, and he will doubtless find other matter in it which will engage his particular interest.

CHARLES SYMONDS

FAILURES IN TREATMENT

Failures in Psychiatric Treatment Edited by Paul H. Hoch, M.D. (Pp 241 54s 6d) New York: Grune and Stratton 1948

In this book are collected the papers presented to the annual meeting of the American Psychopathological Association in 1947. The features which must have made the symposium

interesting and stimulating at the convention in 1947 are to some extent lost in print. There is not enough in common between the various themes, such as insulin shock therapy, the treatment of neurosyphilis, and social case-work, for the whole collection to be anything but a psychiatric scrapbook. Some original data are reported, among which are Dr. Kallmann's three pairs of uniovular twins, whose different fates under the impact of schizophrenic psychoses seemed to be determined by variations in body weight. Dr. Kallmann cites them as evidence for the contention that a genetical approach, rather than stultifying therapy, may suggest new lines of therapeutic attack. In his introduction Dr. Nolan Lewis also refers to the neglect of hereditary factors as a possible cause for failures in treatment, to the existence, besides deep analysis, of other methods of psychotherapy perhaps insufficiently exploited, and to the amount of poor psychotherapy that is given; the schools, he says, are being swamped by students anxious to enter this remunerative field.

The editor sums up and tries to draw some general lessons. He finds it necessary to re-emphasize the importance of accurate diagnosis for successful therapy, and to point out once again that "motivology" and "aetiology" are two different things. The symposium provides the encouraging suggestion that American psychiatry as a whole is retreating a little from the extreme psychodynamic attitude to causation, and that a less fanatical and more medical atmosphere is beginning to appear.

ELIOT SLATER.

PRIMARY TUBERCULOSIS

Die primäre Tuberkulose bei Erwachsenen und Kindern und ihre Entwicklung. By Dr. St. J. Leitner and Dr. R. M. Steinmann. (Pp. 158; illustrated. 15 Swiss francs.) Berne: Medizinischer Verlag Hans Huber.

The authors give a clinical study of primary tuberculosis in 160 adults and 106 children, the cases being followed up for a period of two to eight years. They emphasize that sanatorium treatment should continue until the radiographs no longer show infiltrative changes. These take much longer to disappear than does the acute pneumonic and influenzal picture so often simulated by primary tuberculosis in adults as well as in children. Erythema nodosum was common (33.7% in adults and 6.6% in children); so was pleural effusion (31.8% in adults, 21.7% in children; bilateral in 8 adults). Discussing the relationship between primary tuberculosis and phthisis, the authors consider to be important the frequent observation of an early post-primary spread to the apices. They saw progressive tuberculosis develop from such disseminated foci (i.e., an endogenous source) twice as often as from the primary focus itself. Progressive pulmonary changes following early cavitation of the primary focus or of daughter foci occurred without any recognizable cause—regardless of therapy—and took a rapid and unfavourable course. Those, however, which developed after a longer interval were due to factors weakening general resistance and were quite amenable to therapy.

The authors present their material well and cover most of clinical aspects. Their references to the literature are occasionally erratic and many papers discussed are redundant. On the other hand, the study of Frimann-Dahl and Waaler could have been mentioned, because it was the first to draw attention to the recent dramatic shift of primary infection to adult age groups; nor have they mentioned the extensive discussion of the whole problem held at the Royal Society of Medicine in 1942. There are hardly any observations on pathology, and the authors have not always made use of the pertinent morbid-anatomical facts. For example, we miss a discussion of recrudescence of primary foci as a source of phthisis; it often bridges the long interval between primary infection and phthisis and disposes in such cases of the theory of "exogenous superinfection." These few points, however, do not detract from the distinct value of the book. It lies in its clinical observations and in the demonstration that there is no essential feature in which primary tuberculosis in adults differs from that in children.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Aero-otitis Media and Aerosinusitis. By G. K. Aschan (Pp. 93. No price.) Uppsala: Almqvist and Wiksells. 1948.

An account of experimental histopathological changes due to oxygen deficiency and oxygen poisoning.

Aids to Physical Chemistry. By R. G. Austin, B.Sc., F.R.I.C. 2nd ed. (Pp. 443. 7s. 6d.) London: Baillière, Tindall and Cox. 1948.

An outline for students.

Failure of the Heart and Circulation. By Terence East, M.A., D.M., F.R.C.P. 2nd ed. (Pp. 144. 6s.) London: Staples Press. 1948.

A concise practical account.

There's No Need to Shout. By F. Warfield. (Pp. 152. 8s. 6d.) London: Victor Gollancz. 1949.

The autobiography of a partially deaf woman.

The Child: An Adult's Problem. By A. M. Ludovici. (Pp. 288. 10s. 6d.) London: Carroll and Nicholson. 1949.

Bringing up children discussed for parents and teachers

Experimental Diabetes Mellitus. By E. T. Bell, M.D. (Pp. 31. 7s. 6d.) Oxford: Blackwell. 1949.

A short monograph with references

Le Benzolisme. By V. Raymond and A. Vallaud. (Pp. 174. No price.) Paris: Institut National de Sécurité pour la Prévention des Accidents du Travail et des Maladies Professionnelles. 1948.

The toxicology of the benzols and an account of measures affording protection against them.

Diabetic Manual. By E. P. Joslin, M.D., Sc.D. 8th ed. (Pp. 260. 12s. 6d.) London: Henry Kimpton. 1948.

A practical guide for medical men and their patients.

Frauenheilkunde. By W. Benthin. (Pp. 260 M.14.) Berlin: Urban and Schwarzenberg. 1948.

A manual of gynaecology intended for students and general practitioners.

Principles and Practice of Ophthalmic Surgery. By E. B. Spaeth, M.D. 4th ed. (Pp. 1,044. 75s.) London: Henry Kimpton. 1948.

An illustrated textbook giving details of surgical technique.

The Therapy of the Neuroses and Psychoses. By S. H. Kraines, M.D. 3rd ed. (Pp. 642. 32s. 6d.) London: Henry Kimpton. 1948.

Intended particularly for the non-specialist.

Richtlinien einer Philosophie der Medizin. By A. W. Kneucker, M.D. (Pp. 197. 22s. 6d.) Vienna: Wilhelm Maudrich. 1949.

The author discusses such topics as logic, materialism, ethics, and education.

Röntgen- und Radiumbehandlung. By P. Hess. (Pp. 147. M.13.) Berlin: Urban and Schwarzenberg. 1948.

A practical account of the technique of radiotherapy.

Sex and Marriage. By N. Robertson. (Pp. 46. 2s. 6d.) London: Research Books. 1949.

A short guide to sex conduct for men and women.

Trace Elements in Food. By G. W. Monier-Williams, O.B.E., M.C., M.A., Ph.D., F.R.I.C. (Pp. 511. 30s.) London: Chapman and Hall. 1949.

A study of elements which, in minute amounts, take part in animal and plant metabolism.

Hospital Trends and Developments, 1940-1946. Edited by A. C. Bachmeyer, M.D., and G. Hartman, Ph.D. (Pp. 819. 30s.) London: Geoffrey Cumberlege. 1948.

A collection of articles on hospital administration and allied subjects, selected from literature published between 1940 and 1946.

CORONARY THROMBOSIS TREATED WITH
ANTICOAGULANT DRUGS

Thrombosis of the leg veins, occurring in sick and debilitated adults, is a treacherous hazard of bed rest, unpredictable in its outcome, and at times producing by massive pulmonary embolism the tragedy of sudden death. In a paper appearing elsewhere in this issue Drs. K. P. Ball and H. O. Hughes discuss this danger and urge doctors and nurses to become more "thrombosis-minded." Many workers have now stressed the value of the anticoagulant drugs in the treatment of leg thrombosis, and it is natural that much interest should have been aroused in the possibility of using these drugs in the treatment of coronary thrombosis. Studies such as those of Nay and Barnes¹ have shown how frequently coronary thrombosis is complicated by thrombosis elsewhere. They found thrombotic or embolic complications in 37 out of 100 cases of acute myocardial infarction; 14 out of 100 had pulmonary emboli. Foord² found at necropsy that 48 out of 315 cases of myocardial infarction had pulmonary emboli. It is clear that a safe and effective means of preventing intravascular clotting would reduce the risk of many complicating disasters. Wood³ has even suggested that the treatment of angina at rest with anticoagulants may prevent the onset of some cases of coronary thrombosis.

The most effective anticoagulant is heparin. The disadvantages of this substance are that not enough is produced to meet all demands, repeated injections have to be given, and it is very expensive. Dicoumarol has the advantage that it can be given by mouth, and it is less costly and more readily available than heparin, but its effect upon coagulation is only to prolong by a few seconds a certain stage in the clotting process (prothrombin time). This prolongation of a few seconds may, of course, be quite enough to reduce the chance of blood clotting as it flows over diseased vessel walls and to limit the dissemination of such clots. The greatest disadvantage of dicoumarol is its tendency to produce severe and even fatal bleeding, the avoidance of which requires careful daily laboratory control of its effect on prothrombin time. There seems at the moment to be no way of simplifying this method of treatment for widespread application outside hospitals.

Laboratory investigations have been undertaken to discover whether the anticoagulant drugs will prevent the spread of coronary thrombosis once established. Two reports^{4,5} serve to show that this aspect of the problem is not likely to be settled by experimental coronary ligation in animals. There were no significant differences in the infarcts in dicoumarol-treated and untreated animals, and thrombosis in the smaller vessels within the infarcted area was found just as often in animals receiving dicoumarol as in the control group. Beattie and his colleagues⁵ observed no obvious changes as a result of dicoumarol treatment in dogs with ligated coronary arteries. They emphasize, however, that the experimental procedure in previously healthy vessels is very different from the process in diseased arteries.

If possible, then, the answer must be sought in the clinical results. Glueck and others⁶ have been able to compare 44 patients who received anticoagulant drugs with 44 control patients. The mortality was 45% in the untreated group and 20% in the treated group. Among the former 27% had thrombo-embolic complications, while in the group receiving anticoagulants the incidence of this complication was reduced to 7%. The widely varying outlook even in a carefully collected series such as this still leaves a little doubt, and the American Heart Association wisely set up a committee three years ago to collect more information. The investigators were a group of distinguished men whose collected evidence was obtained from the observation of 800 cases: Irving Wright and his colleagues⁷ have issued a report on the findings. The routine treatment was to administer heparin for the first 48 hours, during which time dicoumarol is coming into action. Thereafter the prothrombin time was held between 30 and 35 seconds by dicoumarol. The cases numbered 368 in the control group and 432 in the treated group; age incidence and severity of the attack were comparable in the two groups. The following figures summarize the results: the percentage mortality in the treated was 14.9 and in the untreated 24; the percentage incidence of thrombo-embolic complications was 11 in the treated and 25 in the untreated; the number of thrombo-embolic complications per 100 patients was 14 in the treated and 36 in the untreated. Closer examination of the figures provides an even more favourable impression than the overall percentages. For example, about half of the treated patients who had thrombo-embolic complications such as venous thrombosis, pulmonary embolism, hemiplegia, and extension of the myocardial infarction developed them before the anticoagulant drugs had time to become fully effective. It is during the first four weeks of the illness that the treatment is most useful: after that the chances of further complications of this type seem to diminish considerably. This report from the U.S.A. is very valuable, and further information from the committee will be awaited with interest. It is to be noted that dicoumarol therapy does not wholly abolish the incidence and the complications of further clotting, but it certainly produces a significant reduction. The anticoagulant regime seems to be of established value in spite of occasional disappointments, and perhaps in time a better and safe anticoagulant will be found.

FRACTURES OF THE NECK OF THE FEMUR

Up to the end of the war of 1914-18 transcervical fracture of the neck of the femur presented an insoluble problem. Non-union was accepted as inevitable. The credit for overcoming this defeatist attitude must be given to Whitman,¹ who showed that union could be obtained by applying the accepted principles of reduction and fixation. This involved encasing the patient in a long spica plaster-of-Paris splint; the treatment was tedious and uncomfortable, and stiffness of the hip and of the knee was a common sequel. Whitman himself never published his results, but it was generally assumed that union could be hoped for in 50% of patients. Löfberg,² following up 153 of his own patients treated by the Whitman method, reported union in 67%, whereas an American Commission³ which reviewed a large number of cases treated in different clinics put the number of successful unions at 30%. Surgeons, now as optimistic as before they had been pessimistic, were not satisfied with these figures and searched for a more efficient treatment.

Although internal fixation had been tried from time to time, it was not until Smith-Petersen⁴ introduced his nail that pinning the neck of the femur came into fashion. Most rationally he pointed out the obvious need for preventing rotation as well as angulation of the fragments and devised his three-flanged nail for the purpose. Smith-Petersen carried out his first operations in 1925. After opening the hip-joint he reduced the fracture and inserted his pin under direct vision. The method was accepted with alacrity by surgeons all over the world. A contribution almost equal to that of Smith-Petersen was made in 1932 by Sven Johansson, of Gothenburg,⁵ who conceived the idea of making a canal in the nail. After reducing the fracture by manipulation he passed a guide wire up the neck of the femur, and when the wire was shown by x-ray control to be well placed he threaded the canalized Smith-Petersen nail over it and hammered the nail home. This procedure avoided opening the hip-joint. Since then various instruments have been devised to enable the guide wire to be correctly placed at its first or second insertion. Probably the most popular one in use in England was that introduced by the late Hey Groves. Many surgeons, including Sven Johansson, scorn the assistance of wire introducers and prefer to rely on their eye to insert the guide wire correctly. Surgeons in different parts of the world have modified the technique—for example, by using a screw instead of a three-flanged nail or by using multiple thin nails. But transcervical fracture of the neck of the femur is now universally treated by threading a Smith-Petersen nail over a guide wire inserted up the neck of the femur into the head. Whitman's abduction-plaster method is a thing of the past.

Pinning of fractured necks of femur has now been employed long enough for the treatment to be assessed.

Early enthusiasm is giving place to the sombre judgment of experience. The results obtained by Sven Johansson have lately been published by Gunnar Odén.⁶ Three hundred and fourteen patients operated on between 1932 and 1941 have been followed up: 27 died at or after the operation, and, since many of the patients were elderly, 104 have died since of natural causes; of the remaining 183 Odén has examined 141, all at least three years after the date of their accident. His detailed analysis answers several questions. The immediate mortality from the injury is less in those subjected to operation than in those treated conservatively. The distinction made by Böhler between the abduction or valgus and the adduction or varus types of fracture is worth retaining. The valgus fracture is frequently impacted and may not need pinning, and whether pinned or not always unites. Johansson prefers to operate on all transcervical fractures, since an impacted valgus fracture may disimpact and become displaced. Impaction cannot be gauged from viewing the radiograph; clinical evidence on this point is alone reliable. And only when the radiograph shows bone trabeculae crossing the old fracture line can one be certain that union has occurred.

Of the varus fractures 90% united after being pinned. In considering this high percentage of successful results it must be remembered that the operations were done by a master surgeon with a special interest in the subject and long experience. Although a fracture table and facilities for taking antero-posterior and lateral radiographs in the theatre are almost indispensable, the operation is not technically difficult. However, an amateur performance is not sufficient: the nail must be inserted far enough and into the centre of the head. Johansson likes the nail to penetrate to within one centimetre of the articular cartilage; other surgeons are not content unless the end of the nail reaches the extreme limit of the bone. Johansson emphasizes the importance of reduction, which he believes is best achieved by skeletal traction applied for seven days. The leg should be allowed to rotate out during this period. External-rotation deformity is not corrected until the patient is on the operation table, when the medial fragment can be prevented from rotating by the use of either the Leadbetter⁷ or the Tavernier⁸ method of reduction.

In Odén's series redisplacement after pinning was common, but was least frequent when the neck after reduction was valgus (27%) and most frequent when it was varus (47%). Over-reduction therefore gave better results than exact reduction. Odén's analysis also showed that the more vertical the nail the less chance there was of redisplacement of the fragments. The position of the nail seemed immaterial, though the length of the nail within the head fragment was all-important. It is self-evident that the maximum length of nail in the head is achieved when the point of the nail lies immediately underneath the centre of the articular area of the head. This should be the surgeon's objective. Early weight-bearing did not increase the risk of redisplacement. Odén concludes that redisplacement in the majority of cases was the result of faulty technique. Though bony union was achieved in 89% of the cases, in only 68% was the clinical result deemed good. In this group the patients walked about as

freely as before the accident, did not use a stick, and did not complain of pain; those at work resumed their former occupation. Another 8% were classed as satisfactory: they used a stick out of doors or had difficulty in tying their shoe-laces or complained of pain. In no less than 24% of the cases the results were classed as bad.

The bad results were due either to non-union or to osteoarthritis of the hip-joint consequent on an aseptic necrosis of the head of the femur. Odén found evidence of aseptic necrosis, past or present, in 38% of the patients. Its frequency varied with the amount of the pre-reduction displacement, but it was commonest in those patients in whom the fragments became redisplaced; it occurred in 16 out of 20 patients who had been repinned. Spotoft⁹ confirms this gloomy prognosis: he found partial or complete necrosis in 21 out of 24 repinned patients. Union may take place in spite of aseptic necrosis, for the fracture did in fact unite in more than half of Spotoft's patients. It is a common belief that aseptic necrosis is more frequent in fractures treated by pinning than in those treated conservatively, but there is no evidence to support this view. The vascular disturbance that eventually discloses itself as an aseptic necrosis of the head of the femur either dates from the time of the accident or is caused by a slow but continuous shifting of one fragment on the other. Aseptic necrosis is usually, though not invariably, associated with faulty technique and subsequent displacement of the fragments.

Is operative treatment for a fracture of the neck of the femur an improvement on Whitman's abduction method? The answer is undoubtedly yes: the mortality is no greater, the end-result is better, and the discomforts of treatment are far less. It is reasonable to assume that two out of three patients with a transcervical fracture of the neck of the femur, treated by a competent surgeon by pinning, will be as good as they were before the accident, and one of four will be left a cripple.

ADVANCES IN MICROSCOPY

In addition to the electron microscope, which is still in the hands of the specialist, the phase-contrast microscope and ultra-violet and fluorescence microscopy are rapidly enlarging knowledge of the cell and of many other structures which come within the domain of the infinitely small. The existing knowledge of the microscopic structure of cells has in the past been derived almost exclusively from the study of fixed and stained material. With the phase-contrast microscope fresh material can be carefully examined. The development and application of the phase-contrast technique to the microscope is due in the first place to Zernicke,¹² and its subsequent improvement by Köhler and Loos³ has placed a valuable tool in the hands of the biologist. Those who wish to acquire some knowledge of the principles and properties of the modern phase-contrast microscope should read Taylor's⁴ description of it. The important property of phase contrast lies in the conversion of phase differences into amplitude differences; the eye is sensitive only to the latter. Thus phase-contrast microscopy will reveal structures which differ in refractive index from the surrounding medium by too small a degree to be made visible by other methods. At the same time, full apertures can be employed and the maximum resolving power

of the objectives under the special conditions of illumination can be brought into use. As a result definition is very greatly improved, and this, coupled with the small depth of focus, provides a picture which in detail and contrast can be rivalled only by the best histological preparations. Furthermore, material can be prepared and examined much more rapidly than by histological procedures. In common with all other methods for the study of living material phase-contrast microscopy does not differentiate between structures which differ only in chemical nature, and to be fully effective it should be used in conjunction with histological methods. Phase-contrast microscopy is of the greatest value in the study of small living cells. Austin and Smiles,⁵ for instance, have studied the fertilization and early development of the rat egg. The magnificent photomicrographs with which their paper is illustrated afford an opportunity for comparing the pictures obtained by direct illumination and by the phase-contrast technique.

Greater resolution and also information about the chemical constitution of the structures studied are obtained by the use of ultra-violet light as a source of illumination, since certain organic compounds possessing specific molecular configurations absorb ultra-violet radiations selectively. The first ultra-violet micrographic equipment was designed by von Rohr⁶ and Köhler⁷ in 1904, but the work of J. E. Barnard was responsible for the development of this type of microscope to its present high degree of efficiency; the apparatus and technique devised by him and Welch⁸ for the study of bacteria and viruses have now largely been standardized for application to living cells. Ludford, Smiles, and Welch⁹ have used this technique with success in the study of living malignant cells. As a result of their investigations Caspersen's¹⁰ conception of a "cytoplasmic protein-forming system" has had to be modified, though there is no disagreement with the general conception of the relation of nucleic acids to protein synthesis. Cytoplasmic protein synthesis probably occurs in the peripheral parts of the cell and not in the immediate vicinity of the nucleus: the site of protein synthesis may very possibly be the mitochondrial-cytoplasmic interfaces.

Fluorescence microscopy also reveals differences in the chemical constitution of cell constituents. The idea of fluorescence microscopy was first suggested in 1911. When cells are treated with a fluorescent dye and are viewed in light of certain wavelengths various tissue structures give out secondary waves. Levaditi and his colleagues,¹¹ for instance, have shown that when ordinary sections from paraffin-embedded material are treated with a dye such as thioflavine S and exposed to wavelengths of light at 3,600 Å a maximum secondary transmission occurs when the wavelength equals 5,150 Å. Under these conditions photomicrographs can be taken on orthochromatic plates. Cytoplasmic inclusions caused by viruses can thus be recognized visually. For instance, the inclusions produced by rabies, vaccinia, and Borna disease fluoresce with an azure blue colour, the same tint as that given out by nucleoli and red cells. Cell protoplasm, nuclei, and collagen fibres, on the other hand, are golden yellow. When viewed by fluorescence microscopy the inclusions are oval or round, without visible structure. The elementary bodies of vaccinia, fowl pox, and lymphogranuloma venereum and the intranuclear inclusions produced by herpes all have a golden-yellow tint.

NATIONAL HEALTH SERVICE EXPENDITURE

ESTIMATES FOR 1949-50

The Civil Estimates for 1949-50, presented to the House of Commons on March 23, show that in the coming year the total cost of the National Health Service in England and Wales will be £228,424,600. This is made up as follows:

	1949-50	1948-9	Increase
	£	£	£
Central Council, etc.	16,000	10,000	6,000
Hospital, specialist, and ancillary services	169,648,500	123,479,000	46,169,500
Services provided by local health authorities	13,275,000	8,758,000	4,517,000
General medical and dental services, pharmaceutical services, and supplementary ophthalmic services	95,661,800	75,340,500	20,321,300
Other services	18,597,000	27,518,542	—
WALES			
Hospital, specialist, and ancillary services	7,882,500	6,118,500	1,764,000
Services provided by local health authorities	750,000	525,000	225,000
General medical and dental services, pharmaceutical services, and supplementary ophthalmic services	6,730,800	4,981,000	1,749,800
Other services	108,000	866,000	—
Gross total	£312,669,600	£247,596,542	£74,752,600
Deduct—			
Appropriations in aid	84,245,000	62,165,400	—
Net total	£228,424,600	£185,431,142	£74,752,600
		Net increase	£42,993,458

The Central Health Services Council and Standing Advisory Committees will spend £11,000 on salaries and wages and £4,000 on payments to members for loss of remunerative time, travelling, and subsistence.

Hospital, Specialist, and Ancillary Services

Here there are increases in every item, though it must be recalled that in 1948-9 the Service was operating only for nine months. The details are as follows:

	1949-50	1948-9
	£	£
ADVANCES TO REGIONAL HOSPITAL BOARDS:		
(a) Capital expenditure	7,000,000	5,251,000
(b) Maintenance and running costs, including specialist services	133,000,000	98,688,000
Total	£140,000,000	£103,939,000
ADVANCES TO BOARDS OF GOVERNORS OF TEACHING HOSPITALS:		
(a) Capital expenditure	1,935,000	1,656,000
(b) Maintenance and running costs, including specialist services	22,000,000	16,505,000
Total	£23,935,000	£18,161,000
CAPITAL EXPENDITURE BY THE MINISTER IN THE ACQUISITION OF LAND, HOSPITALS, AND EQUIPMENT:		
(a) Acquisition of land	3,000,000	250,000
(b) Acquisition of hospitals	100	—
(c) Acquisition of hospital equipment, etc.	100	—
Total	£3,000,200	£250,000
PAYMENTS TO THE MINISTRY OF PENSIONS:		
(a) Medical treatment	5,000	19,000
(b) Surgical appliances—supply, renewal, and repair	1,875,000	473,000
(c) Travelling and other incidental expenses	22,000	8,000
Total	£1,902,000	£500,000
EXPENSES OF THE MINISTER IN CONNECTION WITH RESEARCH:		
(a) Special inquiries into diseases	15,600	8,260
(b) Other services	5,700	5,740
Total	£21,300	£14,000
BACTERIOLOGICAL SERVICE, ETC.:		
(a) Expenses of public health laboratories	730,000	557,000
(b) Payment to the Lister Institute for the production of lymph	18,000	17,500
(c) Cost of 1000 Ls, etc., supplied for immunization purposes	22,000	31,000
(d) Other services	20,000	9,500
Total	£790,000	£615,000

General Medical Services

The expenditure under this heading is estimated as follows:

	1949-50	1948-9
	£	£
(a) Expenses of Executive Councils		
ADMINISTRATION:		
(a) Salaries, wages, etc.	1,350,000	1,026,000
(b) Payments to members for loss of remunerative time, and travelling and subsistence expenses of members and staff	14,000	15,000
(c) Incidental expenses	546,000	460,000
Total	£1,910,000	£1,501,000
GENERAL MEDICAL SERVICES:		
Payments under arrangements made with medical practitioners	£37,825,000	£28,000,000
PHARMACEUTICAL SERVICES:		
Payments under arrangements made for the supply of drugs, medicines, and appliances	£17,530,000	£15,000,000
GENERAL DENTAL SERVICES:		
Payments under arrangements made with dental practitioners	£26,343,000	£17,750,000
SUPPLEMENTARY OPHTHALMIC SERVICES:		
Payments under arrangements made for the testing of sight and the supply of optical appliances	£11,716,000	£12,900,000
TRANSFERRED LIABILITIES:		
Payments in respect of liabilities transferred to executive councils from insurance committees	£1,000	£5,000
(b) Other Expenses		
MEDICAL PRACTICES COMMITTEE:		
(a) Salaries, wages, etc., including remuneration of members	6,000	6,000
(b) Payments to members and staff for travelling and subsistence expenses	1,500	1,000
(c) Incidental expenses	500	250
Total	£8,000	£7,250

In this same section £320,000 is provided for the Dental Estimates Board, as against £171,000; and the Tribunal set up under Section 42 of the Act will cost £300, as against £250. On refresher courses £8,500 will be spent, as against £6,000; £3,000 will be paid to the universities for the provision of courses, and £5,500 will be needed for travelling and subsistence allowances.

In 1948-9 a sum of £4,250,000 was set aside for compensation for loss of the right to sell medical practices. The corresponding allocation for 1949-50 will be £5,000,000, and there is also provided for the first time the sum of £2,250,000 to pay the interest on compensation which must remain outstanding until the retirement or death of the practitioner.

The cost of the superannuation scheme will be £1,955,000, as against £1,360,000, and £150,000 is set aside for compensation for loss of office under Section 68 of the Act, as against £50,000 in the first nine months of the Service. The estimated cost of medical supplies is divided as follows:

	1949-50	1948-9
	£	£
CENTRAL PURCHASE OF MEDICAL SUPPLIES, STORES, AND EQUIPMENT:		
(a) General medical and surgical stores and appliances	2,540,000	2,200,000
(b) X-ray equipment	1,890,000	510,000
(c) Purchase of streptomycin, etc.	490,000	295,000
(d) Government hearing-aids	1,625,000	200,000
(e) Mass radiography units and vans	200,000	127,000
(f) Miscellaneous	255,000	168,000
Total	£7,000,000	£3,500,000

Liabilities transferred to the Minister under Sections 6 and 69 of the Act totalled £17,750,000 in 1948-9. The corresponding figure for 1949-50 is estimated at only £1,751,000. Among other items budgeted for are the expenses of Rampton and Moss Side Hospitals for Mental Defectives (£282,575); the Broadmoor Institution (£168,425); and miscellaneous committee expenses and contributions to the National Association for Mental Health and the Central Council for Health Education, which will account for only £40,000 as against £72,000 for 1948-9.

Wales

A separate estimate for Wales shows that advances to regional hospital boards will total £7,180,000, as against £5,645,000. There is also an increase in the advances to boards

governors of teaching hospitals from £468,500 in 1948-9 to £85,000. The expenses of the Minister in connexion with search on pneumoconiosis are put at £500 for 1949-50 as against £3,000 in 1948-9. Other research services are again estimated at £1,000. The services provided by local authorities all cost £750,000 as against £525,000.

(a) Expenses of Executive Councils

	1949-50	1948-9
ADMINISTRATION:		
(a) Salaries, wages, etc.	£2,000	£67,000
(b) Payments to members for loss of remunerative time, and travelling and subsistence expenses of members and staff	2,000	2,000
(c) Incidental expenses	35,000	36,000
Total	£119,000	£105,000
GENERAL MEDICAL SERVICES		
Payments under arrangements made with medical practitioners	£2,575,000	£1,800,000
PHARMACEUTICAL SERVICES		
Payments under arrangements made for the supply of drugs, medicines, and appliances	£1,470,000	£1,225,000
GENERAL DENTAL SERVICES		
Payments under arrangements made with dental practitioners	£1,861,000	£1,250,000
SUPPLEMENTARY OPHTHALMIC SERVICES		
Payments under arrangements made for the testing of sight and the supply of optical appliances	£704,000	£600,000
TRANSFERRED LIABILITIES		
Payments in respect of liabilities transferred to executive councils from insurance committees	£100	£1,000

(b) Other Expenses

REFRESHER COURSES		
(a) Payments to universities, etc., for the provision of courses	350	—
(b) Travelling, subsistence, and other expenses of persons attending courses	1,350	—
Total	£1,700	—
LIABILITIES TRANSFERRED TO THE MINISTER:		
(a) Liabilities transferred in respect of voluntary hospitals	10	400,000
(b) Liabilities transferred in respect of local authority hospitals	106,990	455,000
Total	£107,000	£855,000

Scotland

The National Health Service in Scotland will cost £31,303,000 in 1949-50, as against £22,907,000 in 1948-9. This is made up as follows:

	1949-50	1948-9	Increase
	£	£	£
Scottish Health Services Council, etc.	1,000	1,000	—
Hospital, specialist, and ancillary services	24,471,000	15,480,000	8,991,000
Services provided by local health authorities	1,100,000	950,000	150,000
General medical and dental services, pharmaceutical services, and supplementary ophthalmic services	12,553,000	10,070,000	2,483,000
Other services	1,530,000	1,807,000	—
Gross total	£39,655,000	£28,308,000	£11,624,000
Deduct—			
Appropriations in aid	8,352,000	5,401,000	—
Net total	£31,303,000	£22,907,000	£11,624,000
	Net increase ..		£8,396,000

Advances to regional hospital boards will total £23,200,000 in 1949-50 (1948-9); expenditure by the Secretary of State on health centres £20,000; on research £20,000; on bacteriological services £90,000; and on blood transfusion services £0,000. Grants to local health authorities will total £1,100,000 in 1949-50 (1948-9) as against £950,000.

The estimates for general medical services are made up as follows:

	1949-50	1948-9	Increase
	£	£	£
(a) Expenses of Executive Councils			
Administration	320,000	250,000	70,000
General medical services	5,400,000	4,000,000	1,400,000
General dental services	2,750,000	2,800,000	—
Pharmaceutical services	1,800,000	1,490,000	310,000
Supplementary ophthalmic services	2,250,000	1,470,000	780,000
Transferred liabilities	11,000	11,000	—
(b) Other Expenses			
Expenses of Scottish Medical Practices Committee	4,000	2,000	2,000
Expenses of Scottish Dental Estimates Board	63,000	40,000	23,000
Expenses of the tribunal under Section 43 of the Act	1,000	1,000	—
Expenses of refresher courses	4,000	6,000	—
Total	£12,553,000	£10,070,000	£2,483,000

The amount set aside for compensation is £575,000 (as against £300,000); for superannuation £140,000 (£75,000); compensation for loss of office £1,000 (£30,000); central purchase of stores and equipment £370,000 (£100,000).

Taken as a whole the Civil Estimates for 1949-50 make it clear that the total cost in the coming year of the National Health Service, National Insurance, and National Assistance will be £555,358,000. In the present financial year, during which these social services will have operated only for nine months, the total cost will be £449,980,000.

If the rate of expenditure in the first nine months had been continued, the annual cost would have been about £600,000,000. These estimates for 1949-50, which are about £45,000,000 below that figure, show that the rate of expenditure is expected to fall.

PROGUANIL IN PROPHYLAXIS AND TREATMENT

COLONIAL MEDICAL RESEARCH COMMITTEE'S RECOMMENDATIONS

The following recommendations on the use of proguanil ("paludrine") in the prophylaxis and treatment of malaria, and suggestions for trial, are issued by the Colonial Office and the Medical Research Council on the advice of the Colonial Medical Research Committee. It should be clearly appreciated that the recommendations are tentative on the basis of present knowledge and that they are subject to review in the light of future experience and experiment.

Prophylactic Use

The dose recommended for suppression of malaria of all types in endemic areas is 100 mg. daily. For children the following dosage is advised: from birth to 5 years—25 mg. daily; from 6 to 12 years—50 mg. daily. When a daily dose is not practicable one dose of 300 mg. should be taken on the same day each week; dosage for children should be in the proportion indicated.

In the case of persons, other than the indigenous inhabitants, who have been resident in an endemic area for some time, or who have been otherwise already exposed to malarial infection, a full therapeutic course (see 1 (a) below) should be taken before entering on the suppressive regimen.

1. P. Falciparum (Malignant Tertian) Infections; Mixed Infections; Undiagnosed Type Infections

(a) *Treatment of Non-immunes.*—Proguanil alone cannot be relied upon to effect radical cure in all cases, and the clinical response with this drug unaided is also somewhat slow. It has been shown, however, that these disadvantages may be overcome by reinforcement with mepacrine on the first day of treatment. The following combined course is recommended for trial: 300 mg. proguanil twice daily for 10 days reinforced on the first day of treatment with three doses of 300 mg. mepacrine, and followed by 100 mg. proguanil daily for

six weeks. (Persons continuing to live in an endemic area should continue their suppressive regimen.)

(b) *Treatment of Clinical Attack in Semi-immune Subjects such as Labour Forces and Rural Populations in Endemic Areas.*—A single dose of 300 mg. proguanil will usually suffice to produce clinical cure. Relapses can be treated similarly as and when they arise. Serious cases should be given emergency treatment (see below).

(c) *Treatment of Malarial "Emergencies."*—For treatment of conditions such as cerebral or algid malaria and where for any other reason the patient is unable to take drugs by mouth, immediate intramuscular mepacrine or intravenous quinine therapy should be employed.

2. P. Vivax (Benign Tertian) Infections

(a) *With the Object of Radical Cure.*—The course advised for adults is 100 mg. proguanil plus 10 mg. pamaquin base (or a corresponding dose of one of the other 8-amino-quinoline derivatives) three times daily for 10 days. The dose for children should be proportionate. Pamaquin should not be given unless the patient can be kept in bed under medical supervision throughout the course; this is particularly important in the case of children. When the patient cannot be kept in bed the alternative course recommended is 100 mg. proguanil three times daily for 10 days followed by a single dose of 300 mg. proguanil on the same day each week for a year.

(b) *Treatment of the Clinical Attack in Semi-immunes.*—As for M.T. malaria.

Unless otherwise stated, the dosage mentioned is that for adults. In recommending the use of a single dose of 300 mg. proguanil for the treatment of the febrile attack in semi-immunes and a weekly dose of 300 mg. for suppressive purposes, the advantages of these procedures are emphasized as (a) bringing an effective antimalarial drug within the economic capacity of village and rural populations of endemic areas of malaria and (b) providing a method of prophylaxis easy of administration.

Preparations and Appliances

ORO-TRACHEAL TUBE INTRODUCER

Dr. J. G. BOURNE, honorary anaesthetist, St. Thomas's Hospital, writes: In a previous article (*British Medical Journal*, 1947, 2, 654) I described a "spring" made in two sizes, Nos. 10 and 8, for use with oro-tracheal tubes, and added: "The Macintosh laryngoscope is preferred to other models. It sometimes happens that the Magill tube is deflected towards the oesophagus at a tangent to its curved blade. To overcome this little difficulty various types of simple introducers have

been used to direct the tip of the tube into the glottis." Illustrated here is the introducer which I have found most satisfactory. It is withdrawn directly the tip of the tube has passed between the cords.

I would like to make two further observations with regard to the use of these "springs." First, when correctly placed in position the tube should lie well to one side or the other of the tongue. If it is left over the dorsum it tends to be extruded from the mouth. Secondly, if a tube and a connecting-piece of suitable fit are chosen they can be firmly locked within the "spring" by being pulled down into it from the bevelled end of the tube. If this fails they can be fixed with tape before tying this round the patient's neck. These "springs" and introducers are now obtainable from Messrs. A. Charles King, 27, Devonshire Street, London, W.1.

I am indebted to Miss J. Dewe, of St. Thomas's Hospital, for the drawings in this and in the original article.

Reports of Societies

SPECIALIZATION—ITS VALUE AND ABUSE

A meeting of the Section of Medicine of the Royal Society of Medicine on March 22 was devoted to a discussion on specialization. Sir ADOLPHE ABRAHAMS presided.

Sir ROBERT YOUNG recalled that when he himself started his clinical work as a student the two senior surgeons at his hospital both also practised ophthalmology, the throat surgeon was lecturer on anatomy, and the physician to the skin department was also assistant physician to the hospital. His own first reaction to the starting of special departments was antagonistic but he soon realized that special departments were necessary, and helpful and to the public advantage. The chief factor in promoting specialization in medicine had been the rapid development of instruments and instrumental methods. The clinical laboratory was a comparatively recent development but it was difficult now to realize to what extent physicians of a former day had to rely upon their senses. One of the unfortunate results of specialization had been that they were liable to cut short their direct observation of the patient and proceed at once to the instrumental or radiological aid.

The only abuses of specialization that he could see were its employment as a cloak for the crank and a spotlight for the quack, but there were many misuses. An important one was the direct approach by the patient or his friends to the specialist and in some cases the ready acquiescence of the specialist in such approach, without the knowledge or approval of the general practitioner. One of the unfortunate results of specialization was the passing of the general physician. The student at all stages of the curriculum was now taught by specialists, the best of whom were enthusiasts. The old physician, however, should not be pushed aside. The time taken in eliciting the history of the patient and making the routine examination was by no means time wasted. It might save a great deal. He was glad that in most hospitals there were still some general physicians.

At the present time the general practitioner was caught in a vortex of forms, certificates, and reports. When he was free from all these he would wish to be the trusted, unhurried, unharried adviser of his patient. Sir Robert Young hoped that some day a Ministry of Health would issue a special instruction to medical schools asking them to revive, restore, and reintroduce doctors of the old type, who were interested in the general make-up of their patients and knew that what they had to deal with was not the mere dysfunction of an organ but a suffering human being.

Integration Needed

Mr. A. DICKSON WRIGHT considered that one result of the National Health Service would be a temporary eclipse of the more general aspects of medicine and surgery. In former days they could recall many men who, after establishing themselves in the front rank as general physicians, came to devote themselves to some special aspect; Sir William Gowers, Sir John Rose Bradford, and Sir William Broadbent were examples. Since then specialization had developed in curious ways and unevenly in different countries. In America it had gone ahead and had been to some extent overdone. In France it had lagged behind, and there the general surgeons did gynaecological operations. The need was to integrate the specialist system with a very good general practitioner system. In America the patients rambled around among the specialists according to their whim or the advice of the hall-porter. Moreover, men in general medicine were almost forced to take up a specialty or lose in the race for places. If they continued their general medicine alongside their specialty they might be regarded as second-rate by the general public. In the teaching hospitals the ultra-specialist was apt to feel that his work was too deep or advanced for the students, and the students, already overburdened, were inclined to think the same, and so the narrow specialist escaped his teaching duties, leaving more and more to the general physician and surgeon. But it was possible that as specialist techniques became simplified a number of specialists would come back into the general field again.

Some specialists Mr Dickson Wright continued, became bored with the monotony and narrowness of their specialty and extended their work into other fields. The neurologist would interest himself in the female pelvic floor, and work in the territory of the gynaecologist, the gynaecologist would start to work on the rectum, owing to the proximity of the parts or he would look on the breast as his domain, the breast being controlled by the ovaries. The thoracic surgeon would concern himself with the alimentary tract and the sympathetic chains and the vagus nerve which passed through his territory. The orthopaedic surgeon was perhaps the worst offender of all in this respect. An opposite abuse was for the specialist to become narrower and narrower. Specialties were developing for cavities, for organs for systems, for ages, for techniques even for ways of thinking. He instanced the treatment of cancer. The cancer specialist, allied with the statistician, might be ready to take control of any organ of the body in which cancer might appear. Specialties in cancer, in diabetes, in rheumatism, in tuberculosis were open to serious criticism.

Another development of specialization was the complicated approach to diagnosis. The specialist surrounded diagnosis with a great deal of investigation. The man who used the gastroscope was assumed to be ahead of the man who did not. The ultra specialists were unwilling to accept simple explanations. There was a tendency to over-elaborate, especially in the matter of diagnosis and to wrap a case up in a large amount of diagnostic ritual which created its own impression on the patient and also gave the specialist's colleagues the feeling that they could not carry on a specialty unless they did all this too. A great many of these evils would disappear if the entrance upon specialism were a little longer delayed. The man who had a good grounding in general medicine and surgery and then quietly went into specialism would serve the public better than the man who became a specialist almost from his first MB.

THE PRESIDENT here remarked that the public was very largely to blame for the abuses of specialization. With the development of instruments it was more or less inevitable that they should expect a specialist for every symptom. The remedy was the proper recognition of the general practitioner and the general physician.

Specialization Justified

SIR HENRY COHEN said that there were some branches of medicine in which a degree of specialization was not only advisable but necessary. In research, the narrower the field the more deeply could one dig and there was no doubt that to-day a great number of advances in medicine came from digging very deeply, with all the instruments available, in a relatively narrow field. Therefore some degree of specialization in research, whether clinical or laboratory or a combination of both might be regarded as justifiable. But while there was some justification for a man pursuing research in renal disease there could be no justification for a man confining his practice of medicine to the kidneys.

He thought it unwise that specialization should enter at all into undergraduate as opposed to postgraduate, teaching. Specialization had led to the provision of clinical material in the undergraduate teaching hospitals which was quite unsuitable for the undergraduate. It had led to the population of undergraduate teaching hospitals being entirely unsuitable for undergraduate teaching. What was needed was that the teacher of undergraduates should be concerned to inculcate a philosophy of medicine.

When it came to practice, he believed that many of the difficulties arose partly from nomenclature and partly because they had not pictured to themselves the kind of case in which specialists played a part. The general practitioner should have been so trained that he had a large outlook in medicine. He might need for the purpose of diagnosis for example, a radiologist, but he should be quite competent to understand the radiologist's films and his report. He might need a pathologist or other specialists because they practised a special branch which was largely concerned at this stage of the case with diagnosis. If, again, his patient needed some special treatment he might have to refer him to a surgeon or some specialist surgeon. Apart from all this, however, there must be patients about whom the general practitioner was uncertain and there should be a group of people to whom he could refer these

difficult problems—namely, the consultants. He likened the consultant to the conductor of an orchestra, one who perhaps could not play the violin as well as his first violinist, or could not play the cello at all but who knew how to get the necessary reaction and response from a number of people. The consultant himself might require certain information for which he would have to refer to a surgeon, a neurosurgeon, a thoracic surgeon, or whomsoever it might be, but there should be general physicians trained as such, and afterwards perhaps some of them might, because of their interest or opportunity, take up cardiology or urology or some other special branch.

One of the dangers of specialization, in Sir Henry Cohen's opinion, was that often the specialist on examining the patient referred to him discovered something in his own department which had no relation to the patient's complaint but with which he persisted in dealing. Focal sepsis was a case in point. He had often seen gallstones removed from a patient whose complaint in fact was due to other causes. It was true that there were gallstones, but a proper history and examination would have shown the cause of the symptoms to lie elsewhere. The surgeon could become so expert in some technical procedures that he took a pride in their performance. But the feasibility of an operation or the completeness with which it could be done was not the best indication for resorting to it. He agreed that there were specialties, both in the field of diagnosis and of treatment, which required such perfection of technique as to justify them. But it must always be remembered that a man was more than the sum of his parts. The gastric system could not be isolated from the nervous system, or the respiratory from the renal system. Jowett said of logic that it was not a science but a trick, and much the same was true of surgery. It was important, more particularly in some special branches of surgery, that there should be competence in technique, both diagnostic and therapeutic, which competence could come only with specialization, and therefore specialization was clearly necessary. But there was no justification for a specialization in which the sole basis of the specialty was an instrument.

Back to the General Physician

Dr MAURICE DAVIDSON remarked that it used to be said, 'If you want pathology, go to the Germans, if you want surgery, go to the French, but if you want to get well, go to the British.' There was a time when that was true, and he was sufficient of a 'reactionary' to wish that that time would come back. One of the outstanding faults about medical teaching was that it had become divorced from the principle of general education which used to be so outstanding a feature of the medical student's curriculum. During the last twenty-five years there had been an increasing tendency on the part of medical committees of teaching hospitals to appoint people by reason of their prominence in some comparatively narrow field. The question would be asked of a candidate 'What has he done?'—meaning 'What contribution has he made to elaborate scientific literature?'—rather than, 'What experience has he had from the wider point of view?' What are his abilities for summing up and dealing with the whole personality of the sick man?

Dr S. L. SIMPSON said that there were large numbers of good specialists practising in all branches of medicine who had done general medicine and pathology for a number of years. The teams which operated for example, at Queen Square or Great Ormond Street were without doubt supreme and were leaders in their respective fields of nervous diseases and children's diseases. The important thing, surely, was neither specialization nor general medicine but sound judgement in both. He agreed that no man should be a specialist who had not a general training. Specialization impoverished general medicine and surgery, and some arrangement should be made whereby, while they had specialists in general hospitals, this impoverishment was avoided.

Dr RICHARD ASHER said that one of the dangers of specialization was that specialists were apt to frighten off the 'general' man, making him feel that certain parts of medicine lay within a prohibited zone. Some psychiatrists, for example, made general practitioners feel that for them to enter upon their patient's worries and anxieties was a blundering invasion. As an example of ultra-specialism he mentioned that a patient was sent to an ophthalmologist, who returned the case saving

that the man had retinitis pigmentosa and that this might indicate the Laurence-Moon-Biedl syndrome, and he therefore suggested that the patient should be examined to discover whether he had polydactyly.

In reply to Dr. Horace Joles and others, Sir HENRY COHEN said that he had no use for the isolated special hospital except where it might be pursuing research or a form of treatment which required special skill. Great as had been the history of Queen Square and Great Ormond Street—two hospitals mentioned in the discussion—he believed it would have been greater had they been part of general hospitals with access to the general outlook in medicine.

ANTIHISTAMINE DRUGS

A meeting of the Section of Experimental Medicine of the Royal Society of Medicine on March 8 was devoted to a discussion on antihistamine drugs. Dr. H. P. HIMSWORTH presided.

Professor W. A. BAIN, of Leeds University, brought forward a quantitative study, by himself and his co-workers, of the action of histamine antagonists in man. From a pharmacological point of view, he said, this work represented an attempt to apply to man quantitative methods which had been applied with success to animals and animal tissues. The intradermal reaction to varying doses of histamine had been determined by the measurement of weal and flare areas on the skin of the forearm, and the extent to which such reactions were modified by histamine antagonists had been determined. It was relatively easy to devise means of obtaining quantitative information about the relative weight-for-weight potencies of the different drugs, the duration of their action, and their therapeutic efficacy. What could not be precisely dealt with quantitatively were the side actions. A group of subjects were given different doses of histamine antagonists—"phenergan," "anthisan," "antistin"—and the weal response computed. It was then possible thus to construct dose-response curves for the different drugs and obtain a measure of their relative weight-for-weight potencies.

Phenergan was found to have the most powerful action on the intradermal weal response, being 7 times more potent than anthisan and 14 times more potent than antistin. It took much longer than the others to establish its full action, reaching its maximum in three hours. The mean time taken by phenergan to fall from maximum to half the maximum action had also been measured; it was 1,170 minutes. The corresponding time with anthisan was 310 minutes, and with antistin 210. Thus phenergan stood out as the most powerful and the longest-acting drug. Because of the lengthy action of phenergan it seemed that it might be a good plan to give this drug, not as customarily three times a day, but once in the twenty-four hours, and that at night, so that the sleepiness it produced would pass unnoticed, while its action might be expected to continue through the following day. On comparing the nightly dose of phenergan required to clear a chronic urticaria with the daily dose of anthisan needed for the same result it was found that on the average only one-fourteenth of the amount of phenergan was necessary—in other words, a nightly dose of 25 mg. of phenergan was equivalent to a daily dose (split up into three or four administrations) of 350 mg. of anthisan. Of the 20 subjects on whom the experiment was tried only one preferred anthisan, 5 had no preference, and 14 preferred phenergan, no doubt because of the relative absence of side effects. The question was raised whether in chronic urticaria the antihistamines were perhaps exhibiting two modalities of action—(1) an increase in capillary permeability, and (2) interference with the liberation of histamine from the tissues.

Types of Asthma

Dr. H. SCHULZ pointed out that the antihistamines did not affect equally the whole action of histamine. The drugs were not necessarily specific; many drug actions overlapped. Most antihistamine drugs were specific in small doses, but tended to have a more widespread action in higher concentrations. When the antihistamines were discovered it was thought that it would be possible to draw a sharp line between histamine-asthma and asthmas of other types, but in fact it had not turned out in that way. Antihistamines had proved useful, but not exactly in the way

expected. As chronic asthma could not be induced in animals it was the more important that the pharmacologist and clinician should work together in the study of these phenomena in man.

Dr. RANYARD WEST said that up to date it could not be stated that antihistamine drugs abolished or prevented the bronchospasm of asthma under any well-controlled conditions. But apart from simple asthma there was another condition of bronchospasm in which histamine liberation occurred. This was curare-bronchospasm, first described in 1935 as a regularly occurring complicating action of crude curare. He described the action of antihistamine drugs in this condition.

Dr. H. G. J. HERXHEIMER said that not all subjects were sensitive to antihistamines, and some were sensitive only to one or two of the drugs. The dosage would be different in every patient and had to be worked out with great care. If these drugs were given to sensitive patients and in the right doses they were most beneficial, but in severe bronchial constriction in an acute attack of asthma no action of the antihistamines would serve. It was only in mild degrees of the condition that the antihistamine was protective. It was effective only in mild asthmatic states.

Nova et Vetera

HISTORY OF CARDIOLOGY

A History of the Heart and Circulation. By F. A. Willius, M.D., M.S. in Med., and T. J. Dry, M.A., M.B., Ch.B., M.S. in Med. (Pp. 456; illustrated. £2.) Philadelphia and London: W. B. Saunders Company. 1948.

This book is full of interesting information. In a sense it is a companion volume to that attractive book *Cardiac Classics* which Willius and Keys have compiled. The authors have approached the subject from three points of view. The writing of medical history has often been unsatisfactory. It so easily becomes a dull, disconnected catalogue of biography. The most interesting method is to trace the development of ideas or knowledge in some special subject. The authors first survey various epochs, beginning with the remote past, continuing with the Mediaeval and Renaissance eras, and ending with the first quarter of the present century. The second part comprises selected biographies in which the lives and writings of the most eminent workers in the subject are described. Finally, for reference, there is a selection of various topics, with a chronological account of the various steps of advance that have been made in each. These three approaches lead to some overlapping, but that does not really matter; in some ways it is an advantage. There are many good illustrations, mainly portraits. The authors have found room for quite long quotations from original descriptions. The index is in two parts—subjects in one and personal names in the other.

There could never be complete agreement on the selection of names. On this side of the Atlantic we have known too little about some of them. Perhaps the chapter on the theological activities of Servetus might have been shorter and so less dull. The English is often heavy and lacks charm and vigour, so that the book is not easily readable. The authors might have said more about the early work on intermittent claudication. The acknowledgment for the portrait of Floyer on p. 78, which was found by Professor Gunn in a book in the Bodleian Library, is really due to the *Medical Press and Circular*, which published it first in about 1934. Too little is said of Floyer's books. Is it correct to say that Trousseau referred to fibrosis of the lung as "Corrigan's disease" (p. 123)? In his 89th lecture he refers to aortic reflux in this way, which is still the practice in France, just as they still call the syphilitic lesion "maladie de Hodgson" (but no "d'Hodgson," as is given in this book on p. 114). At the foot of p. 364 there is a slip which makes Sir Thomas Lewis "K.T."

The study of the origins of our knowledge is only beginning to assume a due proportion. This book will be of value to anyone interested in cardiology and particularly to anyone engaged in teaching. It is a useful addition to that excellent little book on the growth of our knowledge of heart disease that R. O. Moon wrote twenty years ago, and to the Harveian lecture by Rolleston in 1928, which was an admirable account of the advances since the time of Harvey. TERENCE EAST.

Second Thoughts on Proguanil

SIR.—Your issues of Jan. 15 and 29 have only just reached me. I have read with great interest the article by Sir Gordon Covell, Dr. W. D. Nicol, and Messrs. P. G. Shute and M. Maryon on "palutrine" (proguanil) in prophylaxis and treatment of malaria (Jan. 15, p. 88), your leading article (p. 106) entitled "Second Thoughts on Proguanil," and Sir Gordon Covell's letter under the same title (Jan. 29, p. 192).

It has long been clear that not all the claims made for proguanil have been substantiated nor all the hopes fulfilled. I agree, however, with Covell that your leading article overstated the case against proguanil, especially in strongly suggesting that it causes loss of appetite, weight, and energy in those using it in prophylaxis. Since coming to Nigeria I have experienced no such symptoms or even heard of them in others taking prophylactic proguanil. Covell's view that, in spite of certain limitations as a therapeutic agent in an attack of malaria, proguanil has a vast field of usefulness is amply justified.

We tend to judge the value of antimalarial drugs too much by their efficacy in controlling and eradicating malarial infection in Europeans, who have little or no acquired immunity to malaria. The millions of indigenous inhabitants of malarious areas in the Tropics and sub-Tropics are of far more importance, and they often present quite a different problem from that of the European with malaria or exposed to malarial infection. In such populations the three main requirements in an antimalarial drug are cheapness, reasonable effectiveness, and non-toxicity. The need for cheapness is obvious, for such populations are usually very poor. Reasonable effectiveness should include the power to control the fever, to prevent serious complications in the majority of cases, and to enable the patient to resume full activity at an early date. In such populations the eradication of the malarial infection is often undesirable as well as unattainable. Such eradication will almost certainly interfere with the establishment or the maintenance of the acquired immunity which keeps the adult population, at any rate, reasonably free from severe malaria. Moreover, reinfection is often certain, and is likely to be more serious in persons whose previous infections have been eradicated.

Non-toxicity is, I believe, of vital importance, for treatment often has little or no medical supervision. This is where proguanil scores so heavily over mepacrine and even quinine. Covell and his co-authors refer to the toxic effects of mepacrine as being of rare occurrence but by no means negligible, and especially mention mepacrine psychosis, with mental aberration and sometimes maniacal excitement. Your leading article makes light of this and quotes Findlay's figures (1.71 per 1,000) for its incidence in persons taking mepacrine prophylactically or therapeutically. Regarding mepacrine psychosis occurring on prophylactic doses I know little, but such cases are on record. Psychosis on therapeutic doses is far more common, and other authors have quoted far higher figures than Findlay. (I am far from libraries here and cannot give references.) My own experience in the civil population in India in wartime showed that mepacrine psychosis was a very real problem even on a low dose. The theory that it was caused by the malaria and not by the mepacrine has been disproved by the production of the psychosis in an appreciable proportion of healthy volunteers on an ordinary therapeutic course of mepacrine totalling 2.8 g. Admittedly the incidence of psychosis is usually not high: in a disciplined army or in an educated population it will not be a major problem. But in other circumstances the situation will be very different. Only those who have tried to popularize and use mepacrine widely in the little-educated people of a malarious area realize what a devastating effect even a low incidence of psychosis can produce.

Briercliffe, in the very severe malaria epidemic in Ceylon in the 1930's, was possibly the first person to attempt to use mepacrine widely in such circumstances. In his most interesting report on the epidemic he stated that on a dose of 0.3 g. a day for five days the incidence of psychosis was enough to

make the drug so unpopular that its use had to be abandoned in certain valleys affected by the epidemic. In some parts of India in recent years cases of mepacrine psychosis have made the drug extremely unpopular.

All this trouble is avoided by the use of proguanil. I note with interest Covell's suggestion that in the treatment of the attack of malaria mepacrine should be given with proguanil for the first day, and thereafter proguanil only. I agree that the risk of mepacrine psychosis should be greatly reduced, if not abolished, by this means and the efficacy of the treatment increased. In my experience mepacrine psychosis occurs only at or after the end of a course of mepacrine administration lasting at least four days.

I entirely agree with Covell when in his letter he re-emphasizes the great field of usefulness of proguanil in prophylaxis and in treatment in the populations of malarious areas. There appears to be at the moment no other drug which possesses to the same degree the properties essential in such circumstances.—I am, etc.,

Uzuakoli, N.E.R., Nigeria.

JOHN LOWE.

Strain and Paralytic Poliomyelitis

SIR.—The application of x-ray therapy in the vicinity of epiphyses and growing bone generally is now recognized as carrying with it a risk of interfering with normal growth, and therefore should be avoided if possible. However, the following case is instructive in several ways:

A child 2 years of age was treated in 1941 with quite moderate doses of x rays on account of an extensive haemangioma involving the whole of the left leg and buttock. Treatment was directed especially to the foot, which was hypertrophied, but also in smaller amount to the lower half of the left thigh as far as the line of the knee-joint. The haemangioma improved, but during the past two years a slight under-development of the whole leg has been noticed, both in length and girth. I ascribed the condition partly to the previous haemangioma and partly to the irradiation. Recently the child was brought to me on account of falling down without any apparent cause and walking with difficulty. It was evident that the trouble was the leg which I had treated and which I knew to be weaker than the other. An orthopaedic surgeon immediately recognized that the quadriceps muscle was flaccid and that the cause was anterior poliomyelitis. A previous slight malaise with transient pyrexia had been noticed one week previously. The question occurred to me, *Why* should the disease pick on this unfortunate leg? and a possible answer was that it was due to the fact that the leg was weaker than the other and therefore more strained.

Dr. W. Ritchie Russell's masterly article (March 19, p. 465) on the incidence and prevention of serious paralysis has brought this matter vividly to my mind. If my explanation is correct it would suggest that even slight strain may be sufficient to initiate the paralysis, as the difference in strength between the two limbs was previously insufficient to cause anything noticeably unusual in the gait. That the weakened leg was affected by chance is possible, but Dr. Ritchie Russell's findings support the view that it was not so.—I am, etc.,

Stoke-on-Trent.

GEORGE G. BENNET.

SIR.—Dr. W. Ritchie Russell is to be congratulated on his illuminating and graphic account of poliomyelitis (March 19, p. 465). He is to be particularly congratulated on having drawn attention to the possibly far-reaching implications of the relationship between trauma and the development of paralysis. It is only too easy to dismiss such an observation as being either accidental or of no particular importance, but the history of medicine provides many examples of the rich reward to the worker who, perceiving the possible implications of an apparently anomalous finding, follows it up and elucidates its meaning.

If, as Dr. Ritchie Russell suggests, a non-specific stimulus such as minimal trauma is able to modify the physiology of the central nervous system in such a way as to make it more vulnerable to a specific virus infection, then the orthodox conception of the nature of the battle between host and invading organism needs to be reviewed. It will need to include more than a consideration of the number and virulence of the organisms and the antibody and defence reactions of the host. The previous experience of the nervous system will also have to be taken into account.

Speransky, whose book, *A Basis for the Theory of Medicine*, is largely concerned with a study of the role of the C.N.S. in infective diseases, quotes many experiments in line with those referred to by Dr. Ritchie Russell. For example, he shows that after freezing an area of cerebral cortex there is a critical time within which the traumatized area must be excised in order to prevent the subsequent development of epilepsy. After this interval a process is generated in the C.N.S. which is independent of the original stimulus and which has its own dynamism. He shows that an intramuscular injection of tetanus toxin will be ineffective in causing local tetanus if the nerves supplying the muscle are first cocaineized, even though potent toxin can be demonstrated in the nerve trunks about the block. Apparently the specific stimulus of tetanus toxin requires to reach the C.N.S. through the nerve endings.

In a case of recovered tetanus he was able, months later, to provoke a recurrence of the spasms by a "second blow," such as a non-specific injury to a nerve. It was as though the pattern of tetanus had been implanted in the C.N.S. and the specificity of response to subsequent trauma resided more in the C.N.S. than in the nature of the traumatizing agent.

It may be that this approach will throw light on the nature of "susceptibility" and give a deeper meaning to Osler's dictum that there are no illnesses—only ill people. No doubt much of Speransky's work will need to be checked and revised, but, having assimilated its basic concept, it is scarcely possible to spend a day in clinical work without receiving a hint—however tenuous—that the role of the C.N.S. in integrating pathological processes and in organizing their peripheral manifestations is of profound importance to the understanding of medicine.—I am, etc.,

Birmingham

J. S. HORN.

Haematemesis

SIR,—Drs. D. C. Lewin and Sidney Truelove (March 5, p. 383) make the interesting suggestion that in haemorrhage from peptic ulcer the fatality rate is influenced much more by the age of the patient than by the chronicity of the ulcer. I believe that there may be a fallacy in their argument, which involves deducing the pathological state of the ulcer mainly from the duration of the dyspepsia. In his Goulstonian Lectures on the subject of haematemesis and melaena (Sept. 20, 1947, p. 442, and Sept. 27, 1947, p. 478) Avery Jones showed, concerning bleeding from gastric ulceration, that the total history of dyspepsia was no longer in the case of the chronic than in that of the acute lesion. Experience suggests that this may also be true of duodenal cases. Indeed, Drs. Lewin and Truelove recognize this difficulty when they say, "A certain number of patients in the 'unknown' or 'acute ulcer groups' were later found to be suffering from chronic peptic ulcers."

While acknowledging that the authors have done valuable service in re-emphasizing the lowered resistance to haemorrhage of the older patient, I feel that nothing should be allowed to obscure the fact that death is almost always due to bleeding from a chronic ulcer with which arteriosclerosis is often associated. I am, etc.,

Liverpool

NORMAN GIBBON.

Artificial Insemination

SIR,—The attack launched upon the Medical Defence Union by the Archbishop of Canterbury and by Lord Merriman during the House of Lords debate on artificial insemination (reported in the *Journal* of March 26, p. 550) appears to be misdirected and perhaps due to a failure by each of them to appreciate the function and services of that body. It is possible that they may labour under the conviction that the Union sponsors or advocates a particular line of treatment such as artificial insemination. This is not so. The decision whether artificial insemination will constitute appropriate treatment for any given patient rests within the judgment of the doctor in attendance. He and he alone can determine whether or not it is fitting and proper to recommend that line of treatment to remedy a sterile marriage.

The Union, fulfilling a primary function defined in its Memorandum, has consistently warned its members in a suitable manner of the medico-legal dangers associated with artificial

insemination. It has pointed out that they may be accused of negligence, of adultery, or of conspiracy. It has shown to those who desire to undertake this form of therapy the precautions that they should adopt, and it has published two documents which it has been advised by its solicitors are suitable for completion by the parties concerned. It holds no brief for any person who knowingly commits perjury at the time of the registration of the child that is the result of A.I.D.

If the Archbishop's commission had afforded the Union an opportunity of appearing before it when it was in session it is just possible that the persons appointed to give evidence on its behalf would have removed some of the unfortunate misapprehensions that appear to have arisen in their minds.

The law may require alteration, but this should only be effected, if necessary, after the matter of artificial insemination has been fully explored by a Royal Commission or a departmental committee. It would be unfortunate if the Church were once more to align itself with the opponents of a new form of therapy before that therapy has been properly examined by competent authorities and either condemned or confirmed.—I am, etc.,

ROBERT FORBES,
Secretary, The Medical Defence Union

London, W.C.1.

The Arab Refugees

SIR,—The Jewish Society for Human Service is concerned for the Arab refugees, victims of the fighting in the Middle East and now said to number three-quarters of a million. "Their state," wrote *The Times* correspondent in Jericho on Feb. 21, "beggars description." In particular, there is a disastrous shortage of drugs. Of the larger donations promised by governments only the British million pounds has been paid—a pound or so per head of refugees who must be fed, clothed, housed, cured. I have it on the authority of a Minister of the Crown that drugs are so short simply because food is the priority and there is not nearly enough money for everything.

May I beg your readers to send a contribution for this purpose to the Jewish Society for Human Service, 14, Henrietta Street, London, W.C.2? As the Society is collecting for many other needs of these refugees, contributions should be earmarked "Drugs for Arab Relief."—I am, etc.,

London, W.C.2.

VICTOR GOLLANCZ.

Psychiatric Indications for Abortion

SIR,—The annotation on psychiatric indications for abortion (March 19, p. 489) supports the view that with the advent of family allowances, maternity benefit, and a comprehensive health service there is less indication for abortion on "social grounds." From your observation that "nevertheless the over-prolific family will continue to suffer hardship" it is clear that the term "economic" should have been substituted for "social." You go on to say that in Switzerland, where changes in the law relating to abortion have been introduced, the remedy of sterilization is provided for the over-prolific family. You conclude your annotation by suggesting that the wider use of sterilization in women who are unfitted to bear and to rear children would reduce the number of occasions when difficult decisions have to be taken about the therapeutic termination of pregnancy.

In the first place, I venture to suggest that economic factors alone neither justify termination of pregnancy nor sterilization, and in practice it is extremely rare for a request for either to be made on such grounds. When economic factors are advanced it is usually by parents, who sometimes cannot do justice to their existing children. They are invariably quite comfortably off, have planned a small family, and budgeted accordingly. Really badly off parents, who sometimes cannot even afford a contraceptive appliance, never seem to worry very much over the threat to their economy constituted by an unexpected pregnancy. The anxiety reaction on the part of the moderately well-off planning parent is always much greater than that of her hard-up and haphazard contemporary.

Is it seriously suggested that the payment of family allowance or the provision of a free maternity service is going to make all the difference between affording and wanting another child and requesting an abortion or sterilization? To what extent is it considered that the comprehensive health service will

ameliorate the lot of a deserted, unstable, and unmarried mother who has to support an invalid parent?

There are no definite psychiatric grounds for termination of pregnancy. Each case must be considered on its merits. The admission of a suicidal patient to hospital in preference to terminating the pregnancy which determines the morbid impulse can only be justified under very exceptional circumstances. If hospitalization is deemed necessary, surely the severity of the condition warrants removal of the cause, in preference to perpetuating it under conditions which are less favourable and acceptable than those in which the patient was originally situated. It should not be difficult to decide when a pregnancy should not be terminated. There can be fewer occasions on which it could be considered wiser to follow the old adage, 'When in doubt, don't.'

Finally, in my view there is too much glib reference to sterilization of women. There are few indications for sterilization in women which cannot be dealt with adequately by sterilization of the men. In any case sterilization should never be resorted to on such a variable factor as the economic position of the family. Obviously they have no football pools in Switzerland—I am, etc.

London, W1

ELLIS STUNGO

Diagnosis of Early Pulmonary Tuberculosis

SIR,—About two years ago, in common with many other practitioners, I received from the National Association for the Prevention of Tuberculosis a pamphlet on the diagnosis of early pulmonary tuberculosis by Dr. C. H. C. Toussaint, of Bernonsey, and in the last few days I had a second copy. Everyone will agree about the importance of early diagnosis of tuberculosis, but are we helped by this list of indications for immediate x-ray examination?

Cough	including senile patients	Influenza	particularly females
Bronchitis		Febrile chill	
Dyspnoea		P.U.O.	
Laryngitis		Pleurisy, pleurodynia, or pain in chest	
Lassitude		Loss of weight	15-30
Bronchial catarrh		Anorexia	
Haemoptysis		Anaemia	
Ischio-rectal abscess		Debility	
Erythema nodosum		Amenorrhoea	

Now it may well be that most (if not all) cases of tuberculosis of the lungs have one or more of these symptoms at some time before diagnosis, but so do a very great number of others who have no tubercle. Can we in fact, by taking these symptoms as guides, separate out a body of patients of manageable size among whom we may hope to find the majority of the cases of tuberculosis?

I made two counts of my patients; one in July, 1946, gave 17 cases in one week, and one this year, March 8 to March 14, gave 54 cases showing one or more of these symptoms. My total list is 3,000. Even on the summer figure it would mean something over 1 in 4 of my patients in the course of a year—or for an x-ray plant dealing with 50,000 people more chest radiographs in one week than they now do in a year. Films are in short supply even now, and could the tuberculosis officers cope with the numbers?

Indeed, Sir, I would not have troubled you at all about it except that there seems here to be a good idea gone wrong by some exaggeration or want of precision in the presentation of the case.—I am, etc.,

King's Langley

REGINALD FISHER.

Ankylosing Spondylitis

SIR,—In the *Journal* of March 12 (p. 455) you print a letter from Dr. K. Sicher in which he discusses the results of x-ray treatment. I have now had the opportunity of observing such results for nearly 20 years, as I began to work with Gilbert Scott on this subject in 1931 and have seen and treated over a thousand cases.

Usually, but not always, the earlier the case is seen the better the outcome. But a few early cases get worse despite treatment. Some people are extremely sensitive to x-rays, and relative overdosage at the start may destroy their resistance

for months or even years. All symptoms may be banished and apparent arrest of the disease brought about by dosage of the order of one-third to one-half of the 2,500 r referred to. Professor Davidson, of San Francisco, uses even less.

Does the very large dose really eliminate the disease? There is little to indicate that this is so and much to prove the contrary. Exacerbations occur after months or even many years. Meanwhile the BSR is a totally unreliable guide. It is as a rule normal during quiescent periods. But Professor Davidson has shown that the 17-ketosteroids continue to be excreted in excess during remissions, and certain newly discovered biochemical tests, such as those dealing with serum viscosity, are often positive despite normal BSR and absence of symptoms. And what of the 35% of later-stage patients whom Dr. Sicher finds it impossible to benefit by x-rays? Is their sole resort to be the orthopaedic surgeon, who, after all, deals with the results of the disease rather than the disease itself?

Very small doses of x-rays, carefully graduated, will be found to be the answer in some cases, but there remain a considerable number who will require the same continuous care and attention as cases of chronic rheumatism. If cure, or even complete remission, is not possible, nevertheless an attempt should be made to keep such people fit for work and play. To this end any of the usual anti-rheumatic remedies may have to be employed. Gold may be useful, but it has not the dramatic effect which is often observed in rheumatoid arthritis and should be given only in very small doses, say 0.001 g weekly. Polyvalent anti-rheumatic vaccines may also be tried in doses not sufficient to produce general or focal reaction. Bismuth is an alternative to gold, in doses of 0.5 g of sodium-bismuth tartrate once in two weeks. Finally, there is radioactive thorium X, which requires expert administration.

Too often spondylitic patients are told by their doctors, "Nothing can be done." This is nearly always far from the truth.—I am, etc.

London W1

F. HERNIMAN-JOHNSON

Occupational Therapy

SIR,—We have read with interest the review (March 5, p. 397) by Dr. Donald Stewart on *Principles of Occupational Therapy*, edited by Helen S. Willard and Clare S. Spackman. We should like to endorse most sincerely his comments regarding medical prescriptions for occupational therapy. The need for these is felt very strongly by occupational therapists in this country, and they have been striving for them since the earliest days of the profession.

The only points in his review of this book about which we are not entirely happy are the comments, "The authors' description of the ideal organization of a hospital department of occupational therapy may well inspire physiotherapists in Great Britain . . . to demand a more important place in the hospital hierarchy", and again, " . . . will be of wide interest and help to physiotherapists" (my italics). We feel that occupational therapists will also be helped and inspired greatly by this book, and as occupational therapy and physiotherapy are entirely different though frequently interdependent forms of treatment we cannot help feeling that the omission of reference to the occupational therapist is an oversight.—I am, etc.

London SW1

JOYCE OLDNALL,
Secretary, Association of
Occupational Therapists

Penicillin-resistant Staphylococci

SIR,—It would appear from the preamble and summary to the paper entitled 'Frequency of Penicillin-resistant Staphylococci' (March 5, p. 395) that the authors Drs. A. Vourekha and W. Howard Hughes, in recording a 7.6% incidence, are satisfied that penicillin is not losing much ground as an anti-bacterial agent in the treatment of staphylococcal infection. They believe that previous reports have tended to create an exaggerated impression of the waning power of penicillin.

While these authors make no direct reference to the recent work of Barber,^{1,2} one is bound to draw a comparison between the two sets of results. Barber has reported a progressive increase in the percentage incidence of resistant strains from

14% in 1946 to 59% in 1948. Her studies were carried out in a large hospital and her findings represent the percentage incidence of hospital infections due to penicillin-resistant strains. She freely admits that "though penicillin-resistant strains of *S. pyogenes* are now appearing with increasing frequency in many hospitals, this is probably not the case in the community at large."

The strains investigated by Drs. Voureka and Howard Hughes were recovered from the anterior nares of out-patients not suffering from obvious staphylococcal infection. In other words their figure of 7.6% is simply an index of the number of temporary nasal carriers of penicillin-resistant staphylococci. Admittedly 185 of 304 strains were coagulase-positive, but the production of staphylocoagulase implies potential rather than actual pathogenicity.

During 1948 a survey of strains from in-patients and out-patients suffering from staphylococcal infection was undertaken at the Kent and Canterbury Hospital. A report on this study is being prepared for publication, but it would seem timely to give a brief summary in advance. Of out-patient strains, 90% were sensitive and 10% resisted at least 1 unit of penicillin. By contrast only 32% of hospital strains were sensitive. All the resistant strains produced penicillinase. In assessing the value of penicillin in the treatment of staphylococcal infections on the basis of the frequency with which resistant staphylococci are encountered due regard must be paid to the source of the strains investigated.—I am, etc.,

Specialization

SIR.—Another heading might be added to those that Dr. Leonard Simpson makes in his letter (Feb. 26, p. 368): the attitude of the patient towards specialists. One of the promises of the Health Service was of "specialist treatment where for all." Although the operative word is "available," many patients must see this as "specialist treatment for all." Of course "all" do not need specialist treatment, but if they think they are entitled to it they are quite liable to ask for it (the Englishman standing up for his rights). And on what grounds can a G.P. refuse? Only that he does not think it necessary. This does not always go down with the patient, who wants to see specialists.

Doctors who have been in the Army will remember how soldiers on sick parade, when asked their trouble, would reply (for instance), "I want to see the E.N.T. specialist." The doctor's "What about?" startled them like an impertinent question. "Me ears," they would reply. Then, if the medical officer actually looked at their ears, they were puzzled; and if he went so far as to treat them for their troubles they thought it very queer indeed. Surgeries, like sick parades, are in danger of degenerating into sessions at which all that the patients have come for is a chit to see someone else. Eventually the G.P. has only the patients that the chemist used to get, and the specialists get the G.P.'s patients.

There is a danger, too, of doctors achieving the label "specialist" without really knowing a great deal more about their special subject than the average G.P., and it will happen this way. There will be thousands of patients wanting to see specialists about their very special ailments, and someone will pipe up in Parliament that we have not enough specialists. "Then create some," the Minister of Health will say, with a grand gesture. This is what happened in the Army. The Army decided that beyond anything soldiers required psychiatrists. And behold, there were psychiatrists. As the war started there cannot have been so many civilians deserving the title "specialist"—yet the Army was thick with psychiatrists. It was done by the simple process of inviting all M.O.s with the slightest experience in psychiatry to apply for posts in psychiatry. So, as well as the genuine psychiatrists there were myriads who had had the minimum training. (Something like six months H.P. in a mental hospital.) Such a haphazard state of affairs in civilian practice is liable to have for the present generation of doctors a few specialists, but as new specialist-minded generations grow

up, and the N.H.S. "progresses," everything will become much more organized. Who will then be the G.P.? A different sort of person will have to go in for medicine. The Civil Service type of mind will be attracted to the profession, and scientific youngsters of school-leaving age will enter something more exciting than the medical schools.—I am, etc.,

Windlesham, Surrey.

MARGARET C. TAIT.

Pharmacology of the Failing Heart

SIR,—I would like to make some remarks on the article by Professor J. McMichael (Nov. 27, 1948, p. 927). If I would discuss every point in this article with which I disagree it would take up too much of your space, and in many respects it would only lead to repetitions of my teachings which are contained in my book, *Physiology and Pathology of the Heart and Blood Vessels*, Oxford University Press, 1947.

If Professor McMichael would have taken the trouble to read the relevant paragraphs in this book about the effects of digitalis and about the factors which determine the output of the heart (p. 30) he would have made his work more easy and valuable. He would surely have noticed that not only in my mathematical deductions (p. 6) but in my practical conclusions one cannot neglect the most essential factor for the performing of the stroke volume—e.g., the dilatibility of the ventricle. Thus the main effect of digitalis lies in the diminution of the diastolic resistance of the diseased ventricle. If he had drawn this neglected factor into account in his speculations he could have easily explained all his conclusions and doubts, and even why digitalis has no effect on a healthy myocardium.

I am full of admiration for Forssman's bold method of the heart catheterization, but it seems to me that it can hardly give more information than my method either for the determination of the stroke volume or for the diagnosis of the congenital vicia. Certainly, by the application of a catheter into the heart cavities the results of the examination cannot be regarded as the results of a normal heart function. For this and other reasons I wonder why Professor McMichael became so enthusiastic about this by no means indifferent method, and why he abandoned my method, which served him in all his previous work so well.

Many people who have been informed only through the publications of Professor McMichael about his haemodynamic experiments will surely be surprised to hear my claim to be the father of the method which has been applied by Professor McMichael. Heaven only knows what prejudiced him to constantly attribute my sack method to the late Professor Fick, who made his suggestions in the 'eighties of the last century (namely, Vierordt's *Daten und Tabellen*, p. 161), and which induced many authors of great repute like Gréhan and Quinquaud, Zuntz, Hagemann, Loewy, von Schroetter, Wolfberg, Nussbaum, etc., to try to realize the proposal of Fick. But all the attempts did not lead to any practical result. Only in 1906, when I invented my sack method, was it possible to determine the stroke volume of the heart on the basis of Fick's proposed principle, and to lay the basis of our present knowledge of human haemodynamics. All this shows clearly that Fick had no method of his own for the determination of the stroke volume.

In a great series of experiments I proved my methods and published them first *in extenso* in a monograph, "Haemodynamische Studien," in 1909. The essentials of the invention are to respire, for a short time, in a sack filled with nitrogen until the tension of the gases of the blood in the right heart are in equilibrium with the gases in the sack. The analysis of the partial pressure of O and CO₂ in the sack expressed the amount of the blood gases in the right heart. The determination, in connexion with the determination of the O₂ capacity of the blood, further with the determination of the oxygen demand of the body, and the determination of the blood volume and the pulse rate, gave me the opportunity not only to determine as the first in physiological and pathological cases the stroke volume, but all the other haemodynamic features in the living human body. This method has never been superseded, in spite of the fact that many authors have attempted to modify it by insignificant trifles. The 76 sentences of my conclusions stand to-day as firmly as they did 40 years ago.

In the same year as I published my "Haemodynamics" I wrote a treatise, "Zur Diagnose der kongenitalen Vitien," in the *Deutsche Medizinische Wochenschrift*, No. 9, 1909. I used the sack method for the diagnosis of the cor triloculare, where, as is well known, the

blood of the left and the right heart becomes mixed and thus changes the blood gas concentration in the right heart accordingly.

We have possessed, therefore, for 40 years a simple, harmless method for the determination of the gases in the blood, and now the same determination is recommended as a novelty with only the difference that the blood is taken through a heart catheter, which is by no means an indifferent measure and which represents an encroachment on the physiological conditions of the circulation.

Had Professor McMichael further taken the trouble to study my books, which, to my greatest regret I must admit are not easy to understand or everybody, he would surely have rather accepted my subdivision of the cardiac failures in diastolic and systolic insufficiencies and their implications instead of recommending his subdivision of high or low output in failures of the heart, which has no practical significance whatsoever. He also could have learned that his ideas about "back pressure effect" are, plain speaking nonsense. This conception of his proves clearly that he is mixing up in his mind fundamentals of hydrostatics and haemodynamics. He must at least realize that in a closed channel system, as the blood circulation represents, and where the atmospheric changes are negligible, other rules are valid than in the flow in open channels as in a river, where the flow is decidedly influenced by atmospheric changes.

I trust that Professor McMichael will revise the results of his publications according to these suggestions—I am, etc.,

London W 1

J PLESCH

Physiology of the Orgasm

SIR,—The publication of Berg's *Clinical Psychology* once again raises the issue of the place of the orgasm in the therapy of the neuroses. The problem was originally stated by Reich but received negligible discussion at the time. Reich subsequently developed the concept of orgasmic potency as a therapeutic end point, and developed a technique which he considered to be soundly based on the physiology of the autonomic system. If Berg's latest work is an indication that the orgasm is to be discussed once again by psychiatrists it seems a wise preliminary to correct past errors in orgasmic physiology. Discussion can then take place on a scientific basis.

Following Reich Berg thus describes the orgasm in terms of parasympathetic discharge:

"An exceptional degree of sexual tension, conducted along the parasympathetic, would tend to discharge itself as orgasm whereas an excessive degree of anxiety tension, conducted along the sympathetic system, would lead to a condition described in medicine as 'sympatheticotonia,' and would tend to discharge itself in some such phenomenon as an hysterical outburst."

This is an incorrect statement of the position. The standard works on the autonomic nervous system (Kuntz White, and Smithwick) show that the orgasm is a brief period of acute sympatheticotonia occurring at the end of a period of parasympathetic predominance. The latter is the basis for tumescence, and the sympathetic discharge from the upper lumbar segments causes the contraction of the musculature of the genital tract. In these circumstances the physiological basis of Reichian therapy requires complete reassessment—I am, etc.,

London N W 3

P D EEMAN

POINTS FROM LETTERS

Scottish Proverb

Dr J B MILLER (Bishopbriggs Lanark) writes. In a letter on "Whither Tuberculosis?" Dr Patrick Heffernan (Feb 26, p 365) uses the following quotation: "Keep its ain fish guts for its ain fish maws." There are several versions of this old Scots proverb, but all agree that the last two words are "sea maws"—i.e. sea mews or gulls. It is of interest that this was a favourite proverb of Sir Walter Scott and is quoted in *The Antiquary* (chap 15) as follows: "We maun gie our ain fish guts to our ain sea maws" (i.e., of course, that charity begins at home).

Obituary

WILLIAM JOHNSON, M.C., M.D., F.R.C.P.

In all professions there are men and women whose promotion to high office has been due primarily to their solid worth and trustworthiness, their desire for publicity has been small, and only those colleagues who have worked intimately with them have been in a position to assess their other attributes and professional qualities. Such a man was William Johnson, whose death on March 15 at the age of 63 after a brief illness has brought sorrow to his many friends. A reserved and modest man, rather shy, yet possessing a most warm and friendly nature, he was beloved for his generosity of spirit and for his plain and simple faith. It was only natural that his ability as a physician and clinical teacher and his wisdom in counsel should be widely recognized by his appointment to many offices all of which he held with distinction. To each task he brought a well trained, mature mind, full of sound common sense and a rich measure of human understanding.

William Johnson received his early training at Guy's Hospital. After graduating in 1903 he held several resident posts at Guy's and then embarked upon his career as a physician with a special interest in neurology. He was chief clinical assistant in the neurological department at Guy's Hospital, and he proceeded M.D. in 1911 and took the M.R.C.P. in 1912. In the first world war he served with distinction in France, being awarded the Military Cross for conspicuous gallantry and devotion to duty. While on active service, with the rank of major, R.A.M.C., he enjoyed opportunities for pursuing his studies in neurology, and he contributed the article on "Neuroses in France" to the official *Medical History of the War*.

After demobilization Johnson decided to engage in consultative practice in Liverpool, and he was appointed assistant physician to the Royal Southern Hospital and to the Royal Liverpool Children's Hospital. He served these institutions with efficiency and loyalty, and in due course became senior physician to both of them. When his period of active service on the staff came to an end both hospitals showed their appreciation of what he had done and their desire to retain his support and advice by appointing him to their respective governing bodies.

Johnson was elected F.R.C.P. in 1926, and among other appointments he held that of lecturer in clinical medicine and clinical paediatrics in the University of Liverpool. He was president of the Liverpool Medical Institution in 1939, and at the time of his death he was president of the Section of Neurology of the Royal Society of Medicine. These offices brought him much pleasure, but his appointment as censor of the Royal College of Physicians of London was natural, the distinction which pleased him most, and no word could have expressed the gratification which he obviously felt on being selected for this honour. The holding of these and other important offices including examinations for the Universities of Durham and Liverpool, and for the Conjoint Board did nothing to impair his close friendships, many of which were with men much junior to himself. He remained true to his pattern, strong in character, gentle, lovable and loyal by nature, the best of friends. His greatest fortune was in the happiness which his wife and children brought to him, and they have our sympathy in their great sorrow.

So passes one who played a man's part in life and leaves it rich with grateful memories. Sir William Osler expressed the opinion, in *Aequanimitas* that in the physician or surgeon no quality takes rank with imperturbability. Not everyone would agree that this attribute comes first, but by common consent it would certainly be placed high among the requisites of a good doctor. Imperturbability was but one of William Johnson's many qualities, and his epitaph might well be those words of Marcus Aurelius with which Osler prefaced his lecture—"Thou must be like a promontory of the sea, against which, though the waves beat continually, yet it both itself stands and about it are those swelling waves stilled and quieted"—N B C.

Philip Bruce White, who died on March 19 at the age of 57, belonged to the rare genus of truly original research workers. Had he lived the full allotted span he could not have failed to add many further contributions to the rich legacy bequeathed. Although of Scottish descent he was brought up in Bangor, for his father, Philip Jacob White, was the first lecturer in zoology, and later professor of that subject, in the University College of North Wales. It was to his father that he owed an unusually early interest in biological science combined with unique opportunities during childhood and adolescence for its exercise and development. His strong inborn curiosity was thus fostered and led to the acquisition of a width of knowledge and experience which often surprised even his closest friends.

His formal education was obtained first at Friar's School, Bangor, and later at the University College of North Wales, where he took an honours science degree in 1915 with zoology and botany as his principal subjects. His original intention had been to proceed to a medical degree, but to a man of Bruce White's temperament some direct contribution to the war effort was an urgent necessity. Ineligible for military service because of the results of an accident at school, he served a brief apprenticeship in bacteriology at the Lister Institute and a short period as assistant pathologist at Trinity College, Dublin, before obtaining an appointment at Tidworth Military Hospital as a civilian pathologist, in which post he remained until the conclusion of hostilities. In 1919 he went to Aberdeen to assist in an investigation of Isle of Wight disease of bees. The solution of the problem of the aetiology of this disease was an outstanding piece of research for which Bruce White was largely responsible. A few years later he joined W. G. Savage in Bristol in an investigation of food poisoning, sponsored jointly by the Medical Research Council and the Ministry of Health. This was the starting point of his long series of researches on the salmonella, which continued for over a decade and firmly established Bruce White's reputation both as a bacteriologist of note and as a world authority on this group of organisms. His appointment to the scientific staff of the National Institute for Medical Research in 1927 provided the facilities requisite for his intensive study of the antigenic constitution and relationships of the salmonella. Upon that study are based the modern diagnostic methods now in use in laboratories all over the world. This work was followed by similar investigations into the cholera vibrios, which continued almost to the day of his death. An invitation to visit India in 1936 provided an opportunity, eagerly seized, of studying epidemic cholera in the field, and in the following year he went to Egypt to investigate the Cairo outbreak. Side by side with these fundamental researches Bruce White carried out a great deal of notable work in connexion with the preparation and assay of biological standards under the auspices of the Health Organization of the League of Nations. His high scientific attainments were recognized in 1941 by his election as a Fellow of the Royal Society.

Outside his work Bruce White had wide interests. He keenly appreciated many forms of art, and he loved the literature, wines, and cooking of France. He brought zest to all his activities whether serious or trivial, and lived life with a gusto which stimulated those around him. The kindest and most approachable of men, he was nevertheless a shrewd judge of character and could deflate pretence and pomposity with a penetrating comment or witty phrase. Unconventional, unself-conscious, and possessing physical and mental courage of high degree, he was a good companion who will ever be remembered with affection by those who gained the privilege of his friendship. He leaves a widow and two sons, both of whom have adopted the profession of medicine.—W. S.

Dr. ANDREW CONNALL died at his home in Aberdeen on Jan. 26 at the age of 66. Dr. Connall was born in Glasgow and educated at Hillhead High School and later the High School of Glasgow. In 1903 he graduated M.B., Ch.B. at Glasgow University. After holding a number of resident appointments he was given the opportunity of accompanying Sir James Simpson on a special plague mission to the Gold Coast.

Returning to Glasgow in 1909, he took his M.D. degree with highest honours, and had the distinction of being awarded the Bellshouston Gold Medal for his thesis on cerebral meningitis. At the London School of Tropical Medicine he received the diploma in tropical medicine and hygiene in 1910, and five years later he took the Cambridge D.P.H. His work in the West African Medical Service, of which he joined in 1919, obtained early recognition. He was appointed director of the Medical Research Institute at Yaba, Lagos, in 1921, and also deputy director of the laboratory service of Nigeria. He left these appointments in 1924 to return to the Service in 1925. During this long period of twenty-two years he was in the forefront of advances in tropical medicine, and he made a special study of blindness. In all his laboratory work he had the ability and devoted assistance of his wife, by whom he was aided for his services to tropical medicine in West Africa. Dr. Connall was awarded the O.B.E. in 1932. He especially loved golf, and it was there that he made his home when he returned to Scotland. Still comparatively young in years, and energetic in spirit, he felt that he was never too old. His appointment as a first M.O.H. to the Kinner Branch Hospital, Glasgow, gave ample scope for his experience in the field of preventive medicine and in the treatment of infectious diseases. Of efficient, conversant, and sympathetic, he had first space himself during the fourteen years that he directed the hospital this work. At the end of the twenty-two years of office he took post of medical officer and lecturer at the University of Aberdeen. Here he found a big place in a congenial and friendly staff, a fresh outlet for his talents. His popularity with the students and the affectionate regard in which he was held by the staff were a tribute to his outstanding character and to his abilities as a first-class medical teacher. As Dr. Connall was a truly generous soul. He was the perfect host, and the doors of his home were always open to his many friends. While he shunned the glare of publicity, his private acts of generosity were as numerous as the stars in the heavens. He lived a full life, and he was excepted well informed on subjects far removed from medicine. As a collector he placed with zest, as an amateur, confidence in his own judgment and authority. But it was perhaps in another that he found his favourite recreation. Every summer he spent some weeks at Seaside, where he knew every inch and corner for miles around. Gifted with a keen sense of fun and wit, he could see all things in their true perspective. His charming courtesy, his warmth and modesty, were attributes that endeared him to all who knew him.—D. J. M.

Dr. HAROLD JESS CONNELL died on Feb. 18 at his home at Tadworth, Surrey, at the age of 70. He was born at Kew, the son of the late Dr. George Richard Cundell, a former mayor of Richmond. He was educated at St. Paul's School under the redoubtable F. W. Walker. There he got his first glimpse as a fast bowler and a dashing, if somewhat unorthodox, batsman; he was also a good rugby footballer. From St. Paul's he entered the medical school of St. Mary's Hospital, Paddington, and he took the M.R.C.S., F.R.C.P. in 1902. He was house-surgeon at the Huddersfield Infirmary, and afterwards resident medical officer at the Three Counties Mental Hospital, Arlesey, and at the Horton Mental Hospital, Epsom. He then spent some years in general practice at Leeds, and from 1911 to 1935 at Liverpool. From 1935 to 1948 he practised at Tadworth. He served abroad in the R.A.M.C. during the 1914-18 war, part of the time in the Far East. This diversity of experience and training made him a practical general practitioner of real merit, and the people of Surrey are the poorer by his loss. Dr. Cundell married Miss Gold, who survives him with their son.—H. R.

Mr. GEORGE KEITH RIDDOCH was lost in the *Star Tiger* disaster on Jan. 30, 1948. He was the elder son of the late Dr. George Riddoch, and was educated at Rugby and Corpus Christi College, Cambridge, entering the London Hospital in 1938. He was awarded the Frederick Treves Prize in clinical surgery, and graduated in 1941. He married soon afterwards, while carrying out house appointments at Chase Farm Hospital, Enfield. In 1942 he joined the Navy, in which he served till 1946, for most of that time being overseas, at first in destroyers and later in a naval hospital. Riddoch returned to the London after the war and gained the F.R.C.S.Ed. He then went to the West Middlesex Hospital, and was still an assistant there at the time of his death. Keith Riddoch was an exceptional person. He had a first-class intellect and great practical ability, and was consequently already a surgeon at an age at which most show no more than promise. He had had considerable experience both in the Navy and afterwards, but it was not in his nature to follow one subject to the exclusion of all else, and his general training was sound and full. In his last year as a student, the first year of the war, organized teaching was replaced by a

series of resident appointments in 'sector' hospitals and of these he made full use. His bright and cheerful personality won him the friendship of all with whom he came in contact, and his forthrightness and ability won him their respect. He was a delightful companion, with many interests outside medicine, to all of which he applied himself with characteristic energy. Everything he did he did thoroughly. He read widely, he was a skilled carpenter, mended the family's shoes, and extended his knowledge of gardening to the production of a cellar of home made wines—and these were but a few of the diverse interests to be found in a friend with a keen sense of humour and a constant kindness. He knew how easy it is to become the slave of Medicine, and he was determined not to be so. He had achieved happiness, and those of us who knew him well, and knew particularly the complete happiness of his home with his wife and their son Graeme, see much more than the tragically early end of a career that must have been great—and will always be the happier for having known him—J O W D and J R E

Dr CHARLES HAROLD WALKER McCULLAGH died on Feb. 20 at the Queen Elizabeth Hospital, Birmingham, at the age of 74. He graduated at Trinity College, Dublin, in 1897, and proceeded M.D. in 1905. Four years later he took the Cambridge D.P.H. Dr McCullagh came to Birmingham in 1927. He was a very successful general practitioner, and he was held in the highest esteem by his colleagues and patients alike. He had a keen sense of humour and was exceptionally well read. A man of high ideals, his conscientious devotion to duty never failed. His heart was in the work to which he gave himself with unsparring energy until the day of his death. All his colleagues will miss him, and many will regret the loss of a good friend and will sympathize with his widow and two daughters—W MCM

Dr NORTON BURROUGHS CLOWES, who died on Feb. 25, came from a line of well-known Norfolk doctors. His father and both his brothers had been students at Guy's Hospital, where he qualified in 1890. He served in the R.A.M.C. for the duration of the 1914-18 war. He was attached to the Colchester Military Hospital during the recent war, and worked at the Ministry of Pensions at intervals. Although suffering from the after-effects of operations for duodenal ulcer he carried on his work with pluck and determination to the end, and he was loved and respected by all who knew him. Dr Clowes always hoped that he would die in harness and would "pass out quickly when his time came." Both of these wishes were granted. He married the youngest daughter of the late Sir William Robinson, who survives him with two married daughters.

Dr RICHMOND STEEL died at his home in Southport on March 10. He graduated M.B., Ch.B. at Glasgow University in 1909, and even before the 1914-18 war he had begun to take an interest in radiology. A regimental medical officer during the war, on demobilization he decided to give up general practice, and he studied radiology in London, Paris, and Stockholm. He was also a pupil of Thurstan Holland, though to the latter's regret he did not proceed to the then recently created diploma. Settling in Southport, Dr Steel specialized in x-ray work, and when a vacancy occurred he was elected radiologist to the Southport Infirmary. This post he filled for nineteen years. He served also the Ormskirk Hospital and the Southport E.M.S., now the Promenade Hospital, to within a few days of his death. Indeed he had to be prevented from carrying on his examination of films while in bed. It was a great satisfaction to Steel that quite recently a very early carcinoma of the stomach which he detected was operated on successfully by Professor Wells. His films were then used to make slides for use on an American tour, since this was the earliest case that had been sent to Professor Wells. Quite apart from his professional skill, Steel was loved for his personal qualities. His broad humanitarianism, his flair for friendship, and his love of the society of his fellows endeared him to all. He delighted in organizing the social gatherings of the local Caledonian Society, of which he was secretary. Of sincere though unobtrusive religious conviction during the recent war he supported his wife in an outstanding work for the dependants of men in the Forces. The loss of an only son killed almost at the end of the fighting by a missile from a friendly plane, was borne with fortitude by both. To his widow the sympathy of all his colleagues and friends will be extended—W A M

Dr Lina M. Potter writes: I would like to amplify a little the account (*Journal* March 19 p. 503) of Dr Ethel Vaughan-Sawyer's clinical class. Her patients adored her to the extent of tolerating whatever she prescribed. Mrs. Vaughan-Sawyer appreciated this herself and interpolated highly amusing asides for the benefit of the students.

Medico-Legal

ACTION FOR NEGLIGENCE IN DIAGNOSIS

Appeal Allowed

Mr James Forbes Whiteford, an American citizen, was awarded £6,300 damages in an action in July, 1948, in which he alleged negligence against Mr John Bowman Hunter, M.S., F.R.C.S., and Dr Seymour R. Gleed, a medical practitioner of Finchley. Mr Justice Birkett dismissed the action against Dr Gleed, holding that no negligence could be attributed to him. Mr Hunter subsequently appealed against the decision of Mr Justice Birkett, and Mr Whiteford cross-appealed against the dismissal of Dr Gleed from the case.

As has already been briefly noted, Mr Hunter's appeal was allowed and Mr Whiteford's cross-appeal against the dismissal of his action against Dr Gleed was dismissed. The judgment of the Court of Appeal was read by Lord Justice Asquith on March 21.

Summary of Judgment

Lord Justice Asquith said the action was one for damages for negligence and breach of contract brought by a patient against a well-known consultant surgeon and a general practitioner. On March 21, 1942, the plaintiff, a consulting engineer aged 65 or 66, consulted Dr Gleed about certain bladder symptoms. On March 22 at Dr Gleed's request Mr Hunter saw the plaintiff at the Finchley War Memorial Hospital. He found the bladder distended and concluded that this was due to prostatic obstruction. He advised that the bladder should be drained at once and that removal of the prostate should be undertaken in about a fortnight. He then made a suprapubic puncture and inserted a drainage tube, which remained there till April 5, 1942.

On April 5 Mr Hunter operated, intending to remove the prostate, which did not then feel very large. Up to this point the plaintiff had to concede that both doctors were right. Any negligence alleged must be proved in relation to April 5 when Mr Hunter had embarked on the prostatectomy. Mr Hunter opened the bladder. He then examined the interior of the bladder manually and visually with the help of a light. In the trigone area there was an indurated mass of tissue as large as the palm of a man's hand, reddish grey in colour, and of an infiltrating submucous character. He examined this by sight and touch for fifteen or twenty minutes and concluded that it was a cancer and an inoperable cancer. He also concluded that it was this mass, and not the prostate, which had given rise to the retention of urine. If his diagnosis was accurate the only surgical measure possible was excision of the whole bladder, and this he was satisfied the patient could not have borne. After consulting with Mrs Whiteford, and on her advice, he informed the patient through Dr Gleed that he was suffering from inoperable cancer and had only a matter of months to live.

Mr Hunter never saw the plaintiff after April 5. Dr Gleed attended him regularly up to August 21. In July the patient's thighs and genitals became enormously swollen, which Dr Gleed thought to be consistent with a spread through the lymphatic glands of the cancer. Mr Whiteford sailed for New York on August 21 and arrived on September 6 being admitted immediately to the Memorial Hospital 444, East 68th Street. On September 8 Dr Barringer examined the plaintiff using a cystoscope furnished (as only about six cystoscopes in England were at that time) with a rongeur attachment, which allowed the surgeon to take a scraping from any suspected area of the bladder wall. Dr Barringer saw several areas which, in view of Mr Hunter's reported diagnosis, he suspected as cancer; a fairly large diverticulum in the base of the bladder, and a median prostatic bar. He took a scraping from the suspected areas, and microscopic examination revealed no evidence of cancer, merely cystitis. On September 15 Dr Barringer operated and removed a large part of a "small fibrous" prostate, he also emptied the diverticulum of some soft calcareous material and removed the drainage tube. A specimen of the prostate was later examined and showed "benign prostatic hypertrophy." After a long period of convalescence further portions of the

* Second Class Honours.

UNIVERSITY OF DURHAM

Edgar Alexander Park, M.D., D.A., has been appointed Professor of Anaesthetics at King's College, Newcastle-upon-Tyne.

UNIVERSITY OF LONDON

James Livingstone Livingstone, M.D., F.R.C.P., has been appointed a Fellow of King's College.

A Special University Lecture on "Hypersensitivity in Disease" will be delivered by Professor J. H. Biggart, M.D., Musgrave Professor of Pathology in Queen's University, Belfast, at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Friday, April 8, at 5.30 p.m., with Professor Wilson Smith, M.D., F.R.S., in the chair. The lecture is addressed to students of the University and to others interested in the subject and admission is free, without ticket.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examination indicated:

D.P.M.—Part I: L. Couper, R. Halliday, R. McDonald, J. R. M. Mackie, H. J. B. Miller, P. H. Mitchell, Margaret I. Platt.

UNIVERSITY OF LEEDS

At a meeting of the Council of the University on March 16 R. J. Still, M.B., B.Chir., was appointed University Medical Officer from May 1.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The following lectures will be delivered at the College (Lincoln's Inn Fields, London, W.C.) at 5 p.m. each day: April 1, Erasmus Wilson Demonstration by Mr. Guy Blackburn, "Diseases of the Thyroid Gland"; April 28, Hunterian Lecture by Professor Charles F. M. Saint (Capetown), "Stomatodaeal Ruminations, Clinical and Non-clinical"; April 29, Hunterian Lecture by Professor R. I. Harris (Toronto), "Spondylolisthesis." The lectures are open to those attending courses at the College and to all other medical practitioners, dental surgeons, and advanced students.

The Services

NAVAL MEDICAL COMPASSIONATE FUND

A meeting of the subscribers of the Naval Medical Compassionate Fund will be held on Friday, April 22, at 3 p.m., at the Medical Department of the Navy, Queen Anne's Mansions, St. James's Park, London, S.W., to elect six directors of the fund.

DEATHS IN THE SERVICES

Major Robert William Henry Jackson, R.A.M.C. (ret'd.), died at his home in Caernarvon on Feb. 20. He was born in Dublin in 1864, the son of Surgeon-General Sir Robert W. Jackson, F.R.C.S.I. He graduated M.B., B.Ch., B.A.O. in 1897 at Trinity College, Dublin, obtaining the D.P.H. in the same year. He proceeded M.D. in 1892. Major Jackson was chairman of the Caernarvonshire and Anglesey Division of the B.M.A. for three years in succession during the last

war, and represented the Division in 1939, 1941, and 1942 at annual representative meetings. Two years after qualifying he entered the Army at the top of the examination list, and was attached to the second battalion Coldstream Guards. He was later posted to India, where he did excellent work in public health and hygiene as a special officer for the plague departments in Bombay and Calcutta. He saw active service on the North-west Frontier and in the Boer War. In 1907 he volunteered for duty at Kingston, Jamaica, acting as senior medical officer and special health officer, and was highly commended for his services. Major Jackson retired from the Army in 1910, but was again put on the active list during the 1914-18 war, serving as senior medical officer of the Portland Defences, Weymouth, and on hospital ships and troop transports. After the first world war he was placed in charge of the Military Hospital, Clonmel, Ireland. Although 75 years of age at the outbreak of war in 1939, he was not content to remain inactive, and immediately volunteered for duty as medical officer of the ninth battalion R.W.F. camp at Caernarvon, which post he relinquished to act as ship surgeon on the M.V. *Glenapp*, carrying munitions via the Panama Canal and the Dutch East Indies to Singapore. The vessel had to leave this port hurriedly for Australia, returning home via the Cape, owing to the Japanese capture of Singapore. Major Jackson was elected an honorary life member of the British Red Cross Society and the Venerable Order of the Hospital of St. John of Jerusalem, and was the county controller for Caernarvonshire for the Red Cross Society.—I. M. W.

Medical Notes in Parliament

ANALGESIA IN CHILDBIRTH

Mr. BEVAN on March 24 furnished the following information to Lady TWEEDSMUIR. It relates to England and Wales.

Year	Number of Domiciliary Confinements at which Midwives were in Charge (2)	Number of Domiciliary Confinements where Gas and Air Analgesia was Administered by Midwives (3)	Percentage of Col. (3) to Col. (2)
(1)	(2)	(3)	(4)
1938	289,035	1,175	0.4
1939	285,024	1,029	0.4
1940	284,227	1,545	0.5
1941	265,905	1,783	0.7
1942	274,148	2,743	0.6
1943	269,579	3,207	1.2
1944	281,769	5,102	1.8
1945	245,237	7,262	3.0
1946	298,019	20,507	6.9
1947	327,245	43,683	13.3
1948	Information not yet available		

In addition to the domiciliary confinements where a midwife was in charge there were a large number of domiciliary confinements where a doctor was in charge. These confinements numbered 95,543 in 1946 and 96,937 in 1947. Although figures were not available it was known that analgesia or anaesthesia was given in a high proportion of these doctors' cases.

Mr. Bevan further stated that analgesia was being used in the domiciliary midwifery service of 134 of the 145 county and county borough councils. Individual action was being taken with the councils of the counties and county boroughs in which it was not yet being provided.

In reply to another question Mr. Bevan said that in Leeds 100% of the domiciliary midwives employed by the city council and 65% of the hospital midwives were trained in the use of analgesia. In the six months of 1948 in which the National Health Service was in operation 35% of the domiciliary cases attended by the council's midwives had analgesia.

Figures for Scotland

Colonel GOMME-DUNCAN asked on March 22 in how many cases in Scotland was analgesia administered by domiciliary midwives or nurses trained in midwifery in the years 1938, 1944, 1947, and 1948 respectively.

Mr. WOODBURN replied that there could not have been any cases in 1938 and 1944, because it was only in July, 1946, that the Central Midwives Board for Scotland authorized the administration of analgesia by midwives. In 1947 there were 120 cases and in 1948, according to preliminary returns, about 800. Mr. Woodburn further stated that in Scotland training in analgesia was being given to certified midwives at the rate of almost 250 a year, and to all student midwives numbering about 600 a year. He hoped that by the end of 1950 over three-quarters of the midwives then practising in Scotland would have had this training.

Examination of National Service Men

Replying on March 15 to a question by Mr. GRANVILLE SHARP on the medical examination of men for National Service, Mr. ISAACS said there had been no general raising of the medical standards, but a revised system of medical classification, known as the Pulheems system, which was introduced in June, 1948, resulted in a more accurate assessment of a man's physical and mental fitness for service. Certain improvements in the methods of medical examination were also introduced towards the end of 1948. The effect of these changes could not yet be fully assessed, but the latest available figures showed a slight increase in the proportion of men rejected as unfit for service. Two major changes had been made in the medical examination. Mass radiography was undertaken and the examination for ear troubles was more intensive. At the moment the percentage of rejections was 15.9 against 13.5. The increase was mainly due to the innovations which he had mentioned.

"Dogger Bank Itch"

Mr. STEELE, replying on March 15 to Dr. BARNETT STROSS, said he did not know if a ruling had been given on whether fishermen in the North Sea who developed dermatitis from irritation by the sea chervil were entitled to workmen's compensation. Interpretation of the regulations was a matter for the appropriate authorities under the Industrial Injuries Act. This type of dermatitis was the subject of an annotation in our issue of Feb. 26 (p. 358).

Handicapped Persons' Welfare—Advisory Council.—Lord Rushcliffe will be chairman of the Advisory Council on the Welfare of Handicapped Persons appointed under the National Assistance Act. The only medical member of the Council is Dr. Fraser Brockington, who is medical officer of health of West Riding County Council. The Council will advise the Minister on the development of welfare services for the blind, deaf and dumb, and cripples.

EPIDEMIOLOGICAL NOTES

Influenza

There were 360 deaths in the great towns in the week ended March 19, compared with 321 in the previous week. There were small increases in the West Riding towns but the principal increases were in the Midlands; Birmingham, for example, had 37 deaths against 20 in the previous week. In Greater London a small decrease from 83 to 71 deaths was noted.

Discussion of Table

In England and Wales the only notable change in the trends of infectious diseases was a decrease of 1,314 in the notifications of measles. There were decreases also in the incidence of whooping-cough 32, dysentery 16, and scarlet fever 11.

The largest falls in the notifications of measles were Yorkshire West Riding 396, Essex 281, Lancashire 219, Somerset 203, Southampton 188, Nottinghamshire 116, and Leicestershire 109; the largest rises in the notifications were Warwickshire 92, Surrey 79, and Middlesex 58.

Notifications of diphtheria fell by 7 in London and in Lancashire. The only appreciable change in the incidence of scarlet fever was a decrease of 46 in Lancashire. The notifications of whooping-cough fell by 33 in Yorkshire West Riding.

Of the 49 cases of dysentery 19 were notified in Lancashire (Liverpool C.B. 8).

In Scotland, apart from decreases in the incidence of acute primary pneumonia 37 and whooping-cough 16, the notifications of infectious diseases remained practically unchanged. Almost two-thirds of the cases of diphtheria and dysentery were notified in Glasgow.

In Eire there were decreases in the notifications of whooping-cough 43, measles 38, and diarrhoea and enteritis 11. The largest of the local outbreaks during the week were 19 cases of measles in Donegal, Stranorlar R.D., and 17 cases of scarlet fever in Kilkenny, Kilkenny U.D.

In Northern Ireland the notifications of measles declined by 32, while a rise of 22 was recorded in the incidence of whooping-cough. The largest fall in the notifications of measles was 21 in Antrim county, and the largest increases in the notifications of whooping-cough were Belfast C.B. 15 and Tyrone county 14.

Week Ending March 19

The notifications of infectious diseases in England and Wales during the week included scarlet fever 1,209, whooping-cough 2,790, diphtheria 114, measles 16,275, acute pneumonia 1,524, cerebrospinal fever 57, acute poliomyelitis 18, dysentery 35, paratyphoid 2, and typhoid 3.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 12.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of *Poliomyelitis* are for: (a) The 126 great towns in England and Wales, (b) London (administrative county), (c) The 10 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

Medical News

Chloromycetin Synthesized

It has been announced by Parke Davis and Company that the antibiotic chloromycetin (to which reference has recently been made in two leading articles—Aug 28, 1948, p 428, and Dec 25, 1948, p 1113) has been produced artificially in their research laboratories in the U.S.A. A copy of the structural formula was handed to Sir Alexander Fleming in London on March 30. The substance, which can be manufactured on a commercial scale, has been tested clinically and found effective in a number of diseases. The formula is as follows: (I) ψ -1 p nitrophenyl 2 dichloroacetamidopropyl-1, 3 diol

Imperial Cancer Research Fund

At a meeting of the Imperial Cancer Research Fund held on March 8 Dr James Craigie was appointed General Superintendent of Investigations and Director of the Central Laboratory of the Fund from August, 1949, in succession to Professor W. E. Gye. Sir Henry Dale was elected a Life Governor of the Fund in recognition of his distinguished services as a member of council.

Chinese Medical Visitor

Dr Li Fang-Yun, Professor of Public Hygiene in the National Kweichang Medical College, who has been working in the U.S.A., arrived in Britain on March 15 for a month's visit under the auspices of the British Council before returning to China. He is studying the undergraduate teaching of preventive medicine and public health. After spending a week at the London School of Hygiene and Tropical Medicine and then visiting the Woolwich Health Department, the Department of Bacteriology at the London Hospital, and the Ministry of Health, he goes on April 3 to Edinburgh to spend two weeks in the Department of Social Hygiene of Edinburgh University. Dr Li carried out a rural health experiment as technical expert to the Mass Education Movement at Ting Hsien between 1932 and 1937. He was Director of the Public Health Division of the Provincial Health Department of Kiangsi from 1937 to 1939, and in 1945 was appointed Professor of Public Hygiene in the National Medical College.

Professor Haddow in Italy

Professor Alexander Haddow, Professor of Experimental Pathology in the University of London and Director of the Chester Beatty Research Institute at the Royal Cancer Hospital, Fulham Road, left London on March 25 for a lecture tour in Italy under the auspices of the British Council. He is speaking at Milan, Bologna, Florence, Rome, and Turin on 'Recent Advances in the Chemotherapy of Cancer' and 'Mode of Action of the Nitrogen Mustards—a New Working Hypothesis and Its Possible Relation to Carcinogenesis'. His lectures are being arranged with the co-operation of Professor Rondoni, the leading cancerologist of Milan, and of Professor Bastianelli, head of the Cancer Institute in Rome.

The Late Alderman William Hyde

A memorial window was dedicated to the memory of the late Alderman William Hyde, C.B.E., J.P. in the parish church at Toddington, Beds. on Dec 11, 1948. Alderman Hyde, who died in 1945, was the first secretary of the Nuffield Provincial Hospitals Trust, which was founded in 1939. He had a very wide knowledge of medical services, and at the time of his death Sir Farquhar Buzzard wrote of him: "Without any professional training or background he became an acknowledged authority in many spheres of voluntary and benevolent enterprises, he was equally at home in National Health Service in social insurance, in friendly and approved societies, and was recognized as the pioneer of provident associations, which he developed throughout the country. Having always been interested in hospitals, both in the voluntary and local government fields, he naturally and appropriately was chosen by the Nuffield Provincial Hospitals Trust as its leading active officer, thus becoming mainly responsible for that body's efforts to promote the regional co-ordination of health and hospital services."

Australian Postgraduate Education

A Federation to be known as the Australian Postgraduate Federation in Medicine has been formed with the object of encouraging and advancing postgraduate medical education, work, and research in Australia. In addition, the Federation will deal with matters common to more than one Postgraduate Committee, and particularly with the arrangements for visits of teachers to Australia. The members of the Federation are the Melbourne Permanent Postgraduate Committee, the Postgraduate Committee in Medicine in the University of Sydney, the Postgraduate Committee in Medicine of the University of Adelaide, the Postgraduate Medical Education Committee of the University of Queensland, the Western Australian Postgraduate Committee (British Medical Association), and the Tasmanian Postgraduate Committee in Medicine. Provision has been made to admit to membership organizations from New Zealand or

elsewhere on certain conditions. A president, vice president, and an executive committee will be appointed each year, and the executive committee will be elected from persons nominated by the Postgraduate Committee of the State chosen for this purpose by the Federation. The Postgraduate Committee in Medicine in the University of Sydney was selected to provide the first executive. The meetings of the Federation will usually be arranged at times when inter-State meetings of medical organizations are held and will thus ordinarily take place at times of the annual meetings of the Royal Colleges and during Congresses of the British Medical Association.

Hunterian Society

The Council of the Hunterian Society has chosen "The Treatment of Varicose Veins and Their Complications" as the subject for the 1949 competition for the society's gold medal which is awarded for the best essay submitted by any general practitioner. Further details may be obtained from the honorary secretary of the society, Mr J. C. Ainsworth Davis, 48, Wimpole Street, London, W.1, by whom essays must be received by Dec 31.

Influenza Centre

An Influenza Information Centre has been established in the United States at Bethesda, Maryland, to serve as headquarters for American participation in the World Health Organization study of influenza. The centre will be concerned with the identification of influenza virus from outbreaks in the U.S.A., and will assess the usefulness of including new strains in commercial vaccines. It will also serve as a liaison office between American laboratories and the International Influenza Centre, which was established at the National Institute for Medical Research in London in 1947.

Royal Sanitary Institute Prizes

The Council of the Royal Sanitary Institute have announced particulars of the prize essay competitions for 1949. Three prizes are offered: the John Edward Worth Prize of £40 for an essay on practical improvements of appliances or inventions used or proposed to be used in or about dwelling houses; the John S. Owens Prize of £15 for an essay on the ventilation of dwellings and its effect on human health; and the Henry Saxon Snell Prize of 50 guineas for an essay describing suggested improvements in the construction or adaptation of sanitary appliances. Intending competitors should apply to the Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W.1, for a copy of the general conditions.

Wills

Dr Alexander Wilson Gill, of Barlaston, Staffs, left £41,453. Dr Charles Braxton Mooring Aldridge, of Bournemouth, left £56,417. Dr Edward Augustus Bullmore, formerly of Wisbech, S. Peter, Cambs, £36,871. Dr Robert Warren Merrick, of South Croydon, £38,734, and Dr Herbert Edmund Vincent, of Reigate, £4,506.

COMING EVENTS

Royal Microscopical Society

A special meeting of all sections of the Royal Microscopical Society will be held at B.M.A. House, Tavistock Square, London, W.C., on Wednesday, April 6, at 4.30 for 5 p.m., when Dr J. A. Murray, F.R.S., a past president of the society, will be admitted to the Honorary Fellowship. Demonstrations will be given by Mr H. G. Crabtree on 'Liver Tumours Induced by Azo-dyes,' by Dr E. Vasquez Lopes on 'Nerve Endings in the Posterior Pituitary,' and by Mr J. Smiles on 'Recent Applications of Phase-contrast Microscopy to Biological Research.' Short communications will be presented by Dr G. M. Findlay on 'Primary Carcinoma of the Liver,' by Dr L. Foulds on 'Vesical Tumours Induced in Mice by 2-acetylaminofluorene,' by Mr E. Hornum, D.Sc., on 'Lung Tumours Induced by a New Technique,' and by Dr F. R. Selbie on 'Malignant Transformation.' The meeting will be followed by a dinner at the Holborn Restaurant at 7 for 7.30 p.m.

Regional Consultants Committee for East Anglia

A meeting of the Regional Committee of Consultants and Specialists for East Anglia will be held at Rutland Arms Hotel, Newmarket, on Monday, April 11, at 8.15 p.m., when, among other things, the proposed terms and conditions of service of hospital medical and dental staff will be considered. The meeting will be preceded by dinner at 7.15 p.m.

Bristol Medical Reunion Dinner

The Bristol Medical Reunion Dinner will be held at the Victoria Rooms, Bristol, on Wednesday, April 20, 1949, at 7.30 p.m. and not on Saturday, April 30, as was stated in our issue of March 5 (p. 419). Particulars may be obtained from Dr Richard Clarke, Harley Lodge, Clifton Down, Clifton, Bristol, 8.

Society of Anaesthetists of the South-West Metropolitan Region

The Society of Anaesthetists of the South-West Metropolitan Region has arranged a meeting to be held at St. Helier Hospital, Carshalton, Surrey, on Saturday, April 23. Anaesthetists from other areas will be welcome, and those wishing to attend should communicate with the honorary secretary, Dr. W. Alexander Low, Department of Anaesthetics, St. Thomas's Hospital, London, S.E.1, not later than April 4.

University of Leeds Postgraduate Committee

A refresher course for general practitioners will be held at the University of Leeds during the two weeks beginning May 2. The fee for the course is £10 10s., or £5 5s. for one week. Applications for places in the course, and for particulars of the financial assistance available to (a) demobilized general practitioners within one year of release from the Forces, and to (b) doctors engaged in practice in the National Health Service, should be made to the senior administrative Officer, School of Medicine, Leeds, 2, it being stated whether the applicant falls into class (a) or class (b), or whether he proposes to attend at his own expense.

Spanish Paediatric Congress

The 7th National Congress of Paediatrics will be held at Seville on May 9-14 under the presidency of Professor González-Meneses Jimenez and Dr. Carlos Sainz de los Terreros. Information may be obtained from the Secretary-General, Dr. Morales y González, Bailén, 49, Sevilla.

APPOINTMENTS

BAILEY, NEIL, M.B., Ch.B., Senior Resident Medical Officer, Fulham Maternity Hospital.

KEITH, G. ELIZABETH, M.B., B.S., F.R.C.S.Ed., M.R.C.O.G., Honorary Gynaecologist, Hôpital et Dispensaire Français, and Consultant Obstetrician, Wimbledon Antenatal Clinics.

MITCHELL, ROBERT, M.B., Ch.B., D.P.H., Deputy Medical Officer of Health, County Borough of Bury, Lancashire.

SOCIETIES AND LECTURES**Friday**

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—April 1, 5 p.m., "*Diseases of the Thyroid Gland*," Erasmus Wilson Demonstration by Mr. Guy Blackburn.

WHIPPS CROSS HOSPITAL MEDICAL SOCIETY.—At Whipps Cross Hospital, Leytonstone, E., April 1, 8.30 p.m., "*Emergency gynaecology*," by Mr. A. Galletly.

Tuesday

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, London, S.W.—April 5, 5 p.m., "*Problems of Ageing and Chronic Sickness*," Lumleian Lecture by Dr. A. P. Thomson.

Wednesday

HARVEIAN SOCIETY OF LONDON.—At 26, Portland Place, London, W., April 6, 8.15 p.m., "*Cineradiography*," by Dr. Russell J. Reynolds.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330, Gray's Inn Road, London, W.C.—April 6, 12 noon, "*The Larynx: Tuberculosis, Lupus, Syphilis*," by Mr. J. D. McLaggan.

LONDON COUNTY MEDICAL SOCIETY.—At St. James's Hospital, Ouseley Road, Balham, S.W., April 6, 3 p.m., clinical meeting.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE.—At 28, Portland Place, London, W., April 6, 3.30 p.m., "*The Growing Family under Modern Home Conditions*," by Dr. L. G. Housden.

ROYAL MICROSCOPICAL SOCIETY.—(1) At B.M.A. House Tavistock Square, London, W.C., April 6, 4.30 p.m. for 5 p.m., Special meeting of all sections. Demonstrations: "*Liver Tumours Induced by Azo-dyes*," by H. G. Crabtree, M.Sc., A.R.I.C., "*Nerve Endings in the Posterior Pituitary*," by Dr. E. Vasquez Lopes, "*Recent Applications of Phase-Contrast Microscopy to Biological Research*," by J. Smiles, A.R.C.S., F.R.M.S. Short communications: "*Primary Carcinoma of the Liver*," by Dr. G. M. Findlay, "*Vesical Tumours Induced in Mice by 2-Acetyl-amino-Fluorene*," by Dr. L. Foulds, "*Lung Tumours Induced by a New Technique*," by E. W. Horning, D.Sc., "*Malignant Transformation*," by F. R. Selbie, Ph.D. (2) At Holborn Restaurant, London, W.C., 7 p.m. for 7.30 p.m., Dinner.

ROYAL SANITARY INSTITUTE.—At 90, Buckingham Palace Road, London, S.W., April 6, 2.30 p.m., "*The Disinfection of Ice-cream-Serving Equipment*," (a) "*The Problem*," by Dr. J. G. Davies, Ph.D., D.Sc., F.R.I.C.; (b) "*The Use of Quaternary Ammonium Compounds*," by Mr. J. C. L. Resuggan, F.R.I.C.; (c) "*Technique and Results*," by Miss Roberta Ives.

SOCIETY OF PUBLIC ANALYSTS.—At Gas Industry House, 1, Grosvenor Place, London, S.W., April 6, 7 p.m., Ordinary meeting. Papers will be presented and discussed.

Thursday

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, London, S.W.—April 7, 5 p.m., "*Problems of Ageing and Chronic Sickness*," Lumleian Lecture by Dr. A. P. Thomson.

ROYAL PHOTOGRAPHIC SOCIETY: MEDICAL GROUP, 16, Prince's Gate, London, S.W.—April 7, 7 p.m., "*Group Hospital Medical Photography*," by Mr. J. F. V. Larway.

Friday

LONDON UNIVERSITY.—At London School of Hygiene and Tropical Medicine, Keppel Street, W.C., April 8, 5.30 p.m., "*Hypersensitivity in Disease*," by Professor J. H. Biggart.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At Miller Hospital, Greenwich High Road, London, S.E., April 8, 8.30 p.m. Presidential address by Dr. J. M. Loftus.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Chacia.—On Feb. 5, 1949, to Joan (née Tanner), M.B., B.S., wife of Edm. W. Chacia, a daughter—Helen Joan Barbara.

Finlayson.—On March 21, 1949, at Falkirk and District Royal Infirmary, Dr. and Mrs. Finlayson, 8, Rosehall Terrace, Falkirk, a son.

Hamilton.—On March 9, 1949, at the Simpson Memorial Pavilion, Edinburgh Royal Infirmary, to Dr. Gwyneth Maclean Hamilton, wife of Lieut. J. R. Hamilton, a son.

Mather.—On March 20, 1949, at York, to Dr. Maud Mather (née Buchan wife of Dr. John S. Mather, Shipton Thorpe, York, a daughter.

Miller.—On March 21, 1949, at Fernwood House, Newcastle-upon-Tyne, Dr. Eileen Miller (née Baird), wife of Dr. Henry G. Miller, a son.

DEATHS

Carrey.—On March 5, 1949, John Carrey, M.B., B.Ch., B.Sc., Lieut. Colonel, I.M.S., retired, of Eckett Lodge, Beckett Road, Worcester.

Carter.—Joseph Hamilton Carter, M.B., Ch.B., Edin., of Trinidad, B.W.I. Craig.—On March 23, 1949, Charles Hawkins Craig, M.B., Ch.B., Ed., of Station Road, Cheadle Hulme, Stockport, aged 78.

Crawford.—On March 14, 1949, John Martin Maynard Crawford, O.I. F.R.C.S.I., Lieutenant-Colonel, R.A.M.C., retired.

Croxford.—On March 15, 1949, Roland John Croxford, L.R.C.P.&S. L.R.F.P.S.Glas., of Queen's Park, Manchester.

Davenport.—On March 22, 1949, at Middlesex Hospital, London, W., Perc. Arthur Clive Davenport, M.B., Ch.M., Lieutenant-Colonel, I.M.S., ret. of 26, Chestow Villas, London, W.

Dobbin.—On March 13, 1949, at 500, Caledonian Road, London, N., W. Arthur Edwin Dobbin, M.R.C.S., L.R.C.P.

Grimling.—On March 14, 1949, at 22, North Quadrant, Sheffield, Philip New Grimling, M.B., B.S., aged 41.

Hamilton.—On March 17, 1949, at Adelaide, South Australia, Charles W. Hamilton, M.D.

Hay.—On March 9, 1949, Alexander Robertson Forrest Hay, M.B., Ch.B. 1, Golden Hillcock Road, Birmingham, aged 66.

Hayward.—On March 12, 1949, at Hilcot, Wilton, Wiltshire, John Ar Hayward, M.D., M.R.C.P., F.R.C.S., aged 83.

Hope.—On March 21, 1949, at 9, Grove Avenue, Gosforth, Newcastle-upon-Tyne, M. Edith Hope, M.R.C.S., L.R.C.P., D.M.R.E., of 62, Wim Street, London, W.

Henry.—On March 15, 1949, at Ennerdale, Westrow Road, Southampton Robert Henry, M.R.C.S., L.R.C.P., aged 83.

Johnson.—On March 15, 1949, at The Acres Heswall, Cheshire, Will Johnson, M.C., M.D., F.R.C.P.

Johnson.—On March 19, 1949, in a car accident at Oxford, Brian Ing Johnson, B.M., B.Ch.

Kent.—On March 16, 1949, Charles Arthur Kent, M.D., D.P.H., of Do aged 81.

Lync.—On March 19, 1949, at 348, Kew Road, Kew, Surrey, Charles V. Lync, M.R.C.S., L.R.C.P., aged 82.

MacLaren.—On March 17, 1949, Henry Colin MacLaren, M.B., B.Chir., D.A. of 100, Brampton Road, Stanwix, aged 37.

McNair.—On March 7, 1949, at 4, Barrington Crescent, Stockton, David McNair, L.R.C.P.&S.Ed., L.R.F.P.S.Glas.

Martin.—On March 13, 1949, at Manchester, Justin Francis Martin, M.B., B.Ch., D.P.H., aged 36.

Martin.—On March 12, 1949, Alfred Eugene Martin, M.D., of Littlecote, Furze Hill Road, Boreham Wood, Herts, aged 74.

Perkins.—On March 21, 1949, at Tunbridge Wells, Philip Meyler Perkins, M.D., aged 73.

Price.—On March 17, 1949, Clifford Price, M.R.C.S., L.R.C.P., of Homefield, Garratts Lane, Banstead, Surrey.

Steel.—On March 10, 1949, at 32, Roe Lane, Southport, Lanes, Richmond Steel, M.B., Ch.B.

Stewart.—On March 14, 1949, at Princess Beatrice Hospital, Howard Douglas Stewart, L.R.C.P.&S.Ed., L.R.F.P.S.Glas., of 10, Broomhouse Road, London, S.W.

Stewart.—Samuel Dudley Stewart, M.B., Ch.B., Ed., of Trinidad, B.W.I.

Vaughan-Sawyer.—On March 9, 1949, at Mount Vernon Hospital, Northwood, Middlesex, Ethel May Vaughan-Sawyer, M.D., late of 131, Harley Street, London, W.1.

Wadham.—On March 14, 1949, at Ryde, Isle of Wight, Frank Jesser Wadham, M.R.C.S., L.R.C.P.

Whitehead.—Recently, at Bridlington, Arthur Ernest Whitehead, L.R.C.P.&S.Ed., L.R.F.P.S.Glas., aged 75.

Whitting.—On March 17, 1949, at Umbrella Cottage, Lyme Regis, Robert Everard Whitting, M.C., M.D.

Yorke-Davies.—On March 11, 1949, at Nakuru, Kenya Colony, John Wynne Yorke-Davies, M.R.C.S., L.R.C.P.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Spread of Tuberculosis by Books

Q.—Can books handled by tuberculous patients carry tubercle bacilli? If so, are such books, if untreated, dangerous to others, and can they be satisfactorily sterilized at home?

A.—Although observations on the possibility of spreading tuberculosis by books are not numerous, there is little doubt that when books are used by patients with positive sputum tubercle bacilli are deposited on them in varying amount. The degree to which such books become infected varies widely under different conditions, but from the investigations of Kenwood and Dove in 1915, and later of Roodhouse Gloyne, it may be concluded that at least 50% of the books used by patients with open tuberculosis become infected. Fortunately the bacilli become non-viable in about 48 hours when they are dry, so that Tytler considers that two days after the books have left tuberculous patients only 1 to 5% of the bacilli deposited on them are living, provided no moisture is present. After six days the chances of finding living bacilli are remote. There is therefore a risk to non-tuberculous persons, and particularly to children, in handling books used recently by the tuberculous. The risk decreases rapidly after the first two days, and is also dependent on the habits of the particular tuberculous patient. The danger is, of course, greater if the patient moistens his finger when turning over the pages or coughs directly on to the book he is reading. There is little risk in passing books from one tuberculous patient to another, as any superinfection or reinfection will not be large and will in all probability have no serious effect; but when healthy persons are also concerned all books used by the tuberculous should be kept in quarantine for at least one month before redistribution. To make quite certain that no viable bacilli are carried, books should be disinfected either by exposing the pages to bright sunlight for two or three days or by placing them in an oven for 30 minutes with an open dish of water at a temperature of 95° C.

Nice has shown that books can be sterilized in moist air at 80° C. and with 30 to 40% humidity for 32 hours without causing damage. Sterilization by formalin or formaldehyde vapour is falling more and more into disfavour, as it accomplishes only a surface disinfection and possesses small powers of penetration. It is therefore a possible means of disinfection only with books printed on smooth, shiny paper.

Spread of Infection in Fever Hospitals

Q.—In most fever hospitals it is traditional to forbid visiting by relatives and writing letters by patients, to disinfect all clothes worn by patients, and to burn all newspapers and magazines. Should this system be modified in view of recent knowledge of the transmission of infection?

A.—Recent knowledge of the transmission of infection has shown the importance of indirect modes of spread, particularly by infected dust disseminated into the air from fabrics, floors, and fomites. Thus, secondary streptococcal infection among children in hospital with measles or scarlet fever has been associated with gross streptococcal contamination of the bed linen and the dust of the ward. Again, it has been shown that a nasal carrier of haemolytic streptococci will quickly contaminate his clothing, his handkerchief, and his immediate environment. The nose carrier is probably important in the dissemination of other respiratory bacterial infections, such as diphtheria and pneumonia, and possibly of certain virus infections—for example, the common cold. Therefore gross contamination of the patient's clothing or of any material handled by him may be the means of transferring infection to others at a distance, so that the practice of disinfecting clothing and burning newspapers and magazines handled by infectious patients is justifiable; for certain diseases at least. Letters written by patients may be disinfected by formalin

vapour. Visiting by children in infectious diseases wards should be forbidden, and only near relatives of dangerously ill or long-stay patients should be allowed to visit. Since, besides the risk of infection to himself, the visitor may be a source of danger to the patient, he should wear a face-mask and gown when visiting.

Notification of Measles and Whooping-cough

Q.—Does Section 148 of the Public Health Act, 1936 (penalty on exposure of persons knowing that they are suffering from a notifiable disease), apply to whooping-cough and measles, which were made compulsorily notifiable under regulations dated 1940? If Section 148 does not apply, presumably there is some good reason. I shall be glad to have your opinion.

A.—The regulations set out in Section 148 of the Public Health Act, 1936, do apply to measles and whooping-cough, as to other infectious diseases made notifiable under regulation or Order since the Infectious Diseases (Notification) Extension Act, 1899. The copy of the Statutory Rules and Orders, 1938, No. 1100, which apply to London, clearly expresses the Minister's intention—namely, 1 (2) "These Regulations shall come into operation on the 1st day of October, 1938, and shall be enforced and executed by the sanitary authorities for the purposes of the Public Health (London) Act, 1936." The Regulations (No. 204) were applied to England and Wales in February, 1940, superseding the provisional regulations of October, 1939. Nevertheless, in practice it is usual to differentiate between the dangerous infectious diseases, such as diphtheria, smallpox, and typhoid fever, and the diseases made notifiable subsequently by regulation, such as dysentery, poliomyelitis, and measles, as regards the need for strict isolation during life and pending burial in the event of death.

Umbilical Hernia

Q.—What is the most efficient treatment for a moderate degree of umbilical hernia in an infant? How long should palliative measures be carried out before resorting to operation?

A.—In discussing the question of treating umbilical hernia in infants the first point to consider is diagnosis. The true umbilical hernia comes through the centre of the umbilicus and has a "collar" of fibrous tissue from the linea alba that can be felt round its neck under the skin. The supra-umbilical hernia is a bulge just above the umbilicus, and the opening is wide, with thin edges and no collar. The true umbilical hernia will almost invariably close spontaneously—a process that can be much accelerated if protrusion of the abdominal contents is prevented by strapping. Two-inch (5-cm.) inextensible zinc oxide plaster should be pulled across the abdomen to produce a vertical skin fold over the umbilicus; it will stay in position for anything up to a fortnight if kept out of the bath. Placing a penny or a pad under it diminishes its efficiency, and rubber belts are useless, as they never remain in position. The supra-umbilical hernia has no tendency to spontaneous closure, and usually needs operation at the age of 5 or so. Subcutaneous ligation is ineffective in this case, and unnecessary in the true umbilical hernia. An important point in considering treatment is that an umbilical hernia in a child is never dangerous to life, and that the operation may produce a surprising amount of shock.

Peritoneoscopy

Q.—I should be glad if you would give me references to peritoneoscopy. Is it of value, and what are the risks and contraindications?

A.—The method has a limited diagnostic value—limited because only certain areas of the peritoneal cavity can be visualized, because palpation is not possible as in laparotomy, and because of the technical difficulties and risks. The latter are not very great: Ruddock reported one death in 1,500 examinations, in this case from haemorrhage following liver biopsy. Previous inflammatory disease may produce adhesions which not only render examination difficult but may anchor coils of intestine to the anterior abdominal wall so that they are exposed to the risk of puncture when the instrument is introduced. Some surgical emphysema at the site of puncture is usual, but is of small import. The likelihood of the formation of adhesions and the presence of acute intra-abdominal infections are the two chief contraindications. Useful descriptions

of peritoneoscopy will be found in the following articles: Hamilton, J. E., *Surg. Gynec. Obstet.*, 1942, 74, 505; Ruddock, J. C., *ibid.*, 1939, 65, 623; Hosford, J., *British Medical Journal*, 1948, 2, 348; Walker, R. M., *et al.*, *Proc. R. Soc. Med.*, 1943, 36, 445.

Short-wave Diathermy

Q.—Could you tell me the main uses of short-wave diathermy, and could you also recommend some books on the subject?

A.—Short-wave diathermy is used to generate heat, which it produces within the tissues instead of transmitting it by conduction or radiation. The heat can be produced superficially or deeply according to the position of the electrodes. As it is not necessary for the electrodes to be in contact with the skin short-wave diathermy is very convenient. All conditions in which heat is indicated can be treated by this method. It is valuable in the treatment of "rheumatic" conditions, of infections, both superficial and deep (as in the pelvis), and of the neuralgias. For further information the questioner is referred to the very full account of short-wave diathermy in Krusen's *Physical Medicine* (1941, Saunders, Philadelphia) and to Kovacs's *Electrotherapy and Light Therapy* (1945, Kimpton, London).

Inheritance of Fragilitas Ossium

Q.—A patient has just lost her second child, who died from fragilitas ossium congenita. The first child was normal. The mother is young, but nothing is known of her family. The father is also young, and there is no history of a similar case in his family. What is the possibility of subsequent children having this disease?

A.—This is a difficult question to answer. Fragilitas ossium frequently shows dominant transmission, but skipping of generations is observed in a proportion of families. There is some suggestion of familial incidence—that is, a recessive gene—in certain recorded pedigrees, and sporadic cases appear to be common. There is probably a good chance that this is a sporadic instance, whether due to mutation or not, and therefore that any subsequent children will be normal. On the other hand, in view of the absence of the mother's family history, dominant inheritance with skipping is quite possible. There is also a probability, perhaps, that this is a recessive gene, with the usual 1 in 4 chance for any subsequent pregnancy. It is impossible to calculate any overall chance, however approximate; but on the whole it seems likeliest that subsequent children should be normal.

Myopic School-children

Q.—It has been customary to restrict close work for school-children with myopia, but I am given to understand that this is no longer considered necessary. Is this true? What is the present position?

A.—The modification of school work for myopes is still an open question. The problem may be regarded under three heads—the effect on the myopia, the effect on learning, and the psychological effect on the child. The effect on myopia varies according to different observers. A committee considering the "partially sighted child" some years ago found that in high myopia the child who left the myope school was one or two dioptres less myopic than the child who had been through a less restricted training. This seemed to fall in with theory, but unfortunately further investigation showed that both types of patient were equally myopic two years later. In these cases there was no doubt about which group of children were the better fitted for life. On the other hand, a school-teacher faced with a large class has not always the time to help the lame chick along, and so the myope suffers in crowded schools. The child who is segregated in a myope school will probably get more of an inferiority complex than the myope in an ordinary school, who is naturally a "duffer" at games. These are only one or two pointers which show how complex the problem is and why there is a diversity of opinion about the best approach to it. There is no doubt that the present-day trend is towards the type of teaching from which the patient can derive the greatest amount of educational benefit, the myopic changes being relegated to a position of subsidiary importance in coming to a decision.

Claustrophobia

Q.—A man of 35 suffers from claustrophobia. He served with distinction during the war, but since his return to civil employment his condition seems to be getting worse—for instance, travelling in the Tube causes him anxiety. Is there any treatment to alleviate if not cure this state?

A.—This case would appear to be one of an "anxiety state"—that is, a psychological reaction determined on the one side by a susceptible constitution and on the other by some factor of stress in the patient's present situation. Most emphatically there should be an effective treatment. This will depend on discovering the nature of the stress factor, which may need some patient inquiry or may almost lie on the surface. When discovered it may be possible to eliminate it, or at least to reduce its severity. The stress may be due to a combination of circumstances. Many questions arise. Does his job satisfy him? Has he a difficult colleague? How about his home situation—his wife and children? Apart from treatment of the cause, his symptoms may be alleviated by a minor degree of sedation. He could, for instance, take a small dose of a rapidly acting sedative—such as "sodium amytal" 1 to 3 gr. (65 to 200 mg.)—before a Tube journey. The advice of a psychiatrist would probably be helpful; but in essence this is the type of problem a knowledgeable and sympathetic general practitioner could deal with on common-sense principles.

Menstruation at Age 56

Q.—Is it abnormal for a primipara of 56 to be still menstruating? She began her periods at the age of 12. Though now the bleeding is less copious, it is regular and there is no intermenstrual loss. Some hot flushes and headaches occur from time to time, but she is healthy and active, though she has always been obese. Fibroids and retroversion of the uterus have been excluded.

A.—It is unusual, but not very uncommon and not necessarily abnormal, for the menstrual cycle to continue to a relatively late age. Nevertheless it has been suggested that women who continue to menstruate after the age of 50 are more liable to develop carcinoma of the body of the uterus in later years. In the case in question there seems to be no need for alarm or for active treatment at present. If the hot flushes are menopausal the presence of a granulosa-cell tumour in the ovary is unlikely. The patient should be kept under observation and should be warned particularly to report if the bleeding becomes irregular or if she notices any intermenstrual discharge of any kind. In such an event diagnostic curettage should be carried out.

NOTES AND COMMENTS

Fat Intolerance.—Dr. A. A. BATTSON (Kampala, Uganda) writes: With reference to the question and answer on this subject ("Any Questions?" Jan. 22, p. 164), as a lifelong sufferer from fat intolerance may I suggest that yeast (in tablet form) be tried for this condition? I have recently discovered that two tablets taken with a fatty meal will raise my tolerance to normal levels. By a process of experiment I am satisfied that, for me, this is a fact.

Correction.—Owing to a printer's error the last sentence in the first column of p. 263 of the *Journal* of Feb. 12, in the article by Mr. Norman Emblin on "5,000 Deliveries without Maternal Death," was incorrect. It should have read: "It is true, then, to say that the high rate for the borough in the last decade was not due to the number of maternal deaths in the General Hospital or on the Domiciliary Service, where in the same ten-year period there were 4,389 deliveries with the death of only one woman."

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Altology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads, Westcent, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra, Westcent, London*. SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 2 1949

THE SECRETARY REPORTS

THE TRADE DISPUTES ACT

A further and fuller Opinion of Sir Valentine Holmes, K.C., on the vexed question of whether the Trade Disputes Act, 1906, applies to a medical trade union is now available. The substance of the Opinion is as follows:

A trade dispute is defined in the Trade Disputes Act, 1906, as "any dispute between employers and workmen or between workmen and workmen which is connected with the employment or non-employment or the terms of employment or with the conditions of labour of any person." "Workmen" means "all persons employed in trade or industry, whether or not in the employment of the employer with whom a trade dispute arises." There cannot, therefore, be a "trade dispute" or an act done in contemplation or furtherance of a "trade dispute" unless workmen so defined are parties to the dispute.

The following appear to be three essential points: (1) I do not think that doctors are employed in "trade or industry." (2) I do not think that doctors except in special cases such as doctors employed under a contract of service with a local authority or the like can be said to be employed under a contract of service with the Minister of Health or any committee. (3) I do not think that a person can be said to be a workman within the meaning of the Act unless he is employed under a contract of service.

As regards (1), it has been pointed out to me that in *Brimelow v. Casson*, 1924, 1 Ch. 302, it was decided that actors are employed in trade or industry. But Russell J. decided this because he said that "it seems to me that the business of presenting histrionic performances to the public for profit may fairly be described as a trade or industry in which many persons, including actors, are employed." No such reasoning can possibly be applied to the case of doctors, and with all respect it seems to me to be bordering on the absurd to say that doctors are employed in trade or industry." My attention has also been drawn to *National Association of Local Government Officers v. Bolton Corporation*, 1943, A.C. 166. In that case it was held that administrative, professional, and technical officials of the Corporation were "workmen" within the definition of the word in the National Arbitration Order. The definition in that Order of the word "workmen" did not refer to trade or industry and extended to any person who worked under a contract with an employer. I am unable to see how any assistance can be got from that case. In fact, Lord Simon stressed the fact that the definition of workmen in the Order was "entirely different and much wider than that in the Act of 1906" with the result that the words "trade dispute" in the Order were also much wider. There are some dicta of Lord Wright which taken out of their context might support an argument that a professional worker under a contract of service might be said to be a trader. The actual decision in the case throws no light on the meaning of "trade or industry" in the 1906 Act.

As regards (2). There is no authority on this point, and I cannot do more than say that it does not seem to me that the National Health Service Act can be read as making doctors who wish to provide general medical services under the Act servants or employees of anyone.

As regards (3). It might be argued that the 1906 Act applies to everyone who is employed in trade or industry in the sense of being engaged in trade or industry and that it is immaterial that the person has no contract of service with an employer. There is no authority on this point, although I do not think that a case has ever arisen in which persons who were not employed under a contract of service have been suggested to be "workmen" within the definition of the 1906 Act. In my opinion, the word "employed" in the 1906 Act means "employed by an employer" and is not used in the sense of "taking part in a trade or industry." The Act is dealing with the relations between "employers" and "workmen" who are employed: and I find myself quite unable to read Section 5 (3) in the very wide sense suggested above.

It has been said that the perfect diagnosis can be made only in the post-mortem room. Whether or not this is true, it certainly appears that the final answer to a legal conundrum such as this can be given only in the House of Lords in rela-

tion to some legal action involving this issue. In the meantime it can be repeated that, to say the least, there is very substantial doubt whether the Trade Disputes Act of 1906 applies to a medical trade union.

Pools?

Some practitioners have doubted the need for a Central Pool for general practitioner remuneration. Why not remunerate a practitioner, they ask, by paying him an amount equal to the number of persons on his list multiplied by the nationally agreed capitation fee and leave it at that?

For the sake of argument let us assume the simpler method of paying the national capitation fee in proportion to the number of persons on a doctor's list (disregarding for the purposes of this argument the basic salary question). If the capitation fee is x and the number on a doctor's list 2,500, his public income should therefore be $2,500x$. But the practitioner in question is consulted by a person not on his list, that person needing medical attention and to be put on the doctor's list forthwith. The doctor confronted with such a situation and accepting the patient would not be properly paid if the capitation payment began only from that moment or, to be accurate, from the end of the next quarter (the quarterly payments are based on the number of persons on a doctor's list on the first day of the quarter). The doctor has, in fact, been at risk for that person without knowing it and should have been paid a capitation fee while he was at risk. This problem can be met either by some system of back payment or by assuming that doctors generally are at risk not only for the persons on their lists but for others as well. This involves paying a capitation fee in respect of both persons on their lists and persons not on their lists. If there be accepted a measure of responsibility for persons not on doctors' lists as well as those on doctors' lists the most efficient way of paying doctors for that responsibility is to make a national estimate of the total number of persons for whom doctors are at risk, including those who have not actually signed on their lists, and paying general practitioners generally for that total. This, in effect, is the Central Pool method. Put in another way the question is one of collective responsibility.

There is another point. The residents of Wigan go in large numbers to Blackpool for their annual holidays, with the result that Blackpool practitioners spend a good deal of time treating Wigan residents and being paid at temporary-resident rates for such treatment. Where should the temporary-resident money come from for such persons? Clearly it should come from the Wigan pool, for the Wigan doctors have been correspondingly relieved during the absence of those of their patients who have gone to Blackpool. In other words, it is necessary to make adjustments as between the local pools of different areas for temporary-resident purposes. To make this adjustment as between practitioner and practitioner would be a wellnigh impossible task. This adjustment of itself is inconsistent with the simple method of multiplying the number of persons on a doctor's list by x .

Thirdly, the Central Pool conception enables us to secure the application of what is best in Spens—the maintenance of certain levels of remuneration. To maintain the levels, however many doctors enter the Service, means a regular adjustment of remuneration, best made to a total sum estimated in relation to this and other factors. Our recent case is based on an acceptance of the Central Pool principle, for the existence of a Central Pool made possible such cogent arguments and detailed calculations.

National Health Service

HEALTH SERVICE TRIBUNAL

The National Health Service Tribunal for England and Wales has been appointed "for the purpose of inquiring into cases where representations are made that the continued inclusion of a person on the list of an executive council would be prejudicial to the efficiency of the Service in which that person is participating." The Lord Chancellor has appointed Sir Reginald Taaffe Sharpe, K.C., to be the chairman of the Tribunal. The Minister, after consultation with the associations of executive councils, has appointed Mr. Henry Lesser to be a member of the Tribunal, and has also, after consultations with the organizations representative of the professions concerned, appointed the following persons to form the panel of practitioner members of the Tribunal:

Dr. S. A. Winstanley (medical practitioner); Mr. L. C. Atkins (dental practitioner); Mr. G. H. M. Graham (registered pharmacist); Dr. E. G. Mackie (ophthalmic medical practitioner); Mr. W. B. Barker (ophthalmic optician); Mr. J. R. Howard (dispensing optician). The clerk to the Tribunal, appointed by the chairman with the Minister's approval, is Mr. R. B. Cooke (solicitor).

The Tribunal is the only body that can decide that a person's name should be removed from an executive council's list, and the practitioner may appeal to the Minister of Health to reverse the decision. If the Tribunal decides that the name should remain on the list the Minister cannot intervene.

CLAIMS FOR COMPENSATION

Practitioners are reminded that though the last date for submission of claims was Oct. 31, 1948, the Minister was empowered by regulation to accept claims during the ensuing six months where it could be shown that delay was unavoidable. This period of grace ends on April 30, 1949, and no undertaking can be given that any claim submitted for the first time after that date will be considered.

PRESCRIBING FOR OUT-PATIENTS NEW FORM

Hospitals and clinics in the National Health Service have dispensaries or other arrangements for dispensing prescriptions for their out-patients. The Minister of Health has therefore arranged for a new prescription form (E.C.10.H.P.) to be used in such cases.

The form is similar to Form E.C.10, but is printed on pink paper. After being completed by a medical practitioner on the hospital staff it is presented by the patient to a pharmacist on the executive council list. The appliances prescribed on this form may be only those included in the list in the Third Schedule to the General Medical and Pharmaceutical Regulations.

TRAINEE ASSISTANT SCHEME

The General Medical Services Committee has set up a sub-committee to consider the working of the trainee assistant scheme in the light of the recommendations of the Spens Committee on the remuneration of general practitioners.

MILEAGE ALLOWANCE TO MEMBERS OF MEDICAL BOARDS

As a result of representations made by the Association the Ministry of Pensions, Ministry of National Insurance, and the Ministry of Labour and National Service have agreed to pay a medical practitioner serving on a medical board or on an advisory panel a mileage allowance of 1s. a mile each way for every mile outside a radius of two miles between the boarding centre and his home, or any centre from which he practises, whichever is the nearer (provided he has not received or claimed a similar allowance otherwise). The mileage allowance is subject to a maximum of 20s. for each return journey, and came into effect as from March 17, 1949.

FEES FOR EMERGENCY TREATMENT AND ANAESTHETICS

After consultation with the B.M.A. the Ministry of Health has prepared two model forms: (a) E.C.31 (claim for payment for the services of an anaesthetist); (b) E.C.32 (claim in respect of emergency treatment). The Minister suggests that executive councils should confer with local medical committees with a view to adopting these forms for use. Variations should not be made without the Minister's specific approval. In both model forms the fees to be paid have been omitted. The Minister suggests that the following scales might be appropriate:

Scale of Fees for Emergency Treatment

	£	s.	d.
(1) Attendance at surgery after 8 a.m. and before 8 p.m.	5	0	
(2) Attendance at surgery after 8 p.m. and before 8 a.m.	7	6	
(3) Visit (day)	7	6	
(4) Night visit—i.e., visit made between the hours of 8 p.m. and 8 a.m. in response to a call received between those hours	15	0	
(5) Setting of fractures	1	1	0
(6) Reduction of dislocation	10	6	
(7) Administration of general anaesthetic other than nitrous oxide or ethyl chloride	1	11	6
Administration of nitrous oxide or ethyl chloride	10	6	
(8) Minor surgical operation requiring local or general anaesthetic	10	6	

Payment for Anaesthetist

As in item (7) of scale of fees for emergency treatment.

Executive councils and committees are free to suggest modifications of the scales to meet local conditions. The Minister suggests that the new scales should operate in respect of treatment given on or after April 1.

Payment for emergency treatment and anaesthetics for July 5, 1948, to March 31, 1949, is in accordance with the distribution scheme(s) for the area(s) of the former insurance committee(s) included in the L.E.C.'s area.

PAYMENT FOR SUPPLY OF DRUGS

General practitioners should be paid for drugs and appliances supplied from July 5, 1948, to March 31, 1949, in accordance with the following arrangements.

Practitioners Supplying All Drugs

Where under the General Medical and Pharmaceutical Services Regulations, 1948, a practitioner has arranged, or is required by the council, to supply certain patients (dispensing patients) with all requisite drugs and prescribed appliances, he may elect to be paid for the drugs and appliances which he actually supplies, in which case payment should be made on the basis of the Drug Tariff.

Where a practitioner elects to receive a capitation fee in respect of each dispensing patient to cover the liability to supply all drugs and prescribed appliances other than those included in the special list, the amount payable in respect of the period from July 5, 1948, to March 31, 1949, will be at the rate of 6s. 6d. a year based on the number of dispensing patients at Jan. 1, 1949, with adjustments if he has not provided this service throughout the period. In addition to drug capitation fees a practitioner will receive payment on the basis of the Drug Tariff for any drug or appliance in the special list actually supplied by him to the dispensing patient.

Drugs Administered by Practitioners

Payments in respect of drugs and appliances (other than those mentioned in the special list) required for immediate administration or application, or for use before a supply can conveniently be obtained by the patient, should be made at the rate of 2s. 6d. per annum for every 100 persons included in the practitioner's list, except those to whom he has arranged

or is required to supply all necessary drugs and prescribed appliances.

If, in special circumstances, payment at a higher rate was authorized for the area of the executive council under the arrangements in force under the National Health Insurance Scheme, payment should be made at that higher rate for the current period. Drugs and appliances in the special list supplied by a practitioner to a person on his list, or drugs supplied under paragraph 7 (9)(ii) of Part 1 of the First Schedule to the General Medical and Pharmaceutical Services Regulations, should be paid for on the basis of the Drug Tariff. The drugs referred to in the paragraph cited are those administered personally by the doctor other than drugs administered before a supply can be obtained otherwise under the regulations.

The balances due to doctors in respect of drug capitation fees for the period from July 5, 1948, to March 31, 1949, must have been paid not later than March 31. Payments made on the basis of the Drug Tariff should be made as soon as possible after the accounts have been received from the Pricing Office.

PRESCRIBING PREPARATIONS

The Minister of Health has decided that Allen and Hanburys' Malt and Oil, Wander's Malt and Oil, and Radiostoleum should not be included in the list of preparations classified by the 1929 Advisory Committee as those preparations the prescribing of which by insurance practitioners was justified only in special circumstances (for list and full proviso see *Supplement*, Jan. 8, p. 12, Table II). The Minister considers, however, that malt-and-oil preparations and vitamin preparations should be regarded as drugs only when prescribed for a definite therapeutic purpose. Form E.C.10 may then be used. When ordered as a routine measure for healthy children and in like circumstances they are regarded as food adjuncts and should not be prescribed on Form E.C.10.

DISABLEMENT¹ ADVISORY PANELS FEES

Following representations by the Association, the Ministry of Labour and National Service has now intimated that as from March 17 medical members of Disablement Advisory Panels will receive a fee of £2 5s. for a session of 1½ hours to 2½ hours; for an attendance of less than 1½ hours the fee will be £1 15s.

MEDICAL PRACTICES ADVISORY BUREAU LOCUMS AND ASSISTANTS

One of the important functions of the Bureau is the introduction of assistants and locums. In this field difficulties are inherent because of fluctuations in supply and demand. While the number of practitioners undertaking locum work, or seeking the short-term assistantships, is fairly constant, increasing temporarily after the half-yearly examinations, the demand for locums to cover periods of illness or holidays and for assistance during the winter rush is subject to peak periods, during which demand greatly exceeds supply.

At present the demand for both locums and assistants is very heavy, and practitioners willing to undertake this work are urged to get in touch with one of the branches of the Medical Practices Advisory Bureau. Doctors starting a career in general practice are reminded that service as locums does not make them ineligible for appointments as trainee assistants.

The demand for trainee assistants is also very heavy, and the Bureau is maintaining a register of those seeking such posts. It appears that many are reluctant to apply because they dislike the term "trainee"; but any difference between the subsidized post and the so-called "straight assistantship" is more apparent than real, and the former offers many advantages to those without previous experience.

One reason why there is a shortage of assistants is that, as a result of the war, large numbers of those entering general practice for the first time are married and anxious to obtain almost at once positions which offer security and early prospects of advancement. They are therefore loath to accept

appointments which do not offer a view to succession or partnership. While their needs are acknowledged, it should be borne in mind that an assistantship without view can be regarded as a "jumping-off point" and can offer adequate remuneration and experience while the doctor is seeking a more permanent opening.

It is probable that for some time to come the number of applicants for practices or shares will be greater than the number of these available, and that, in the case both of vacancies allocated by executive councils and of partnerships offered by doctors in established practices, those with previous experience in general practice have a greater chance of success. What is perhaps more important is that the doctor with experience, being a more acceptable candidate for an opening, has consequently a wider choice of area and type of work.

DEVELOPMENT CHARGES

A circular explaining certain provisions of the Town and Country Planning Act, 1947, has been issued by the Ministry of Town and Country Planning to local authorities in England and Wales. Under the Act permission is required before any development of land can be carried out. Development includes the making of any material change in the use of any buildings or other land.

The question whether a development charge would be involved where a medical practitioner acquired a property, formerly used entirely for residential purposes, with the intention of occupying it as his residence but also carrying on his practice there is discussed in the circular. It states that the Minister has considered in consultation with his legal advisers the implications of "material change" in this connexion and that he has formed the opinion that the use by a professional man, whether a doctor or a dentist, of one or two rooms in his private dwelling for the purpose of consultation with his patients would not constitute a material change in the residential character of the existing use so long as the professional use remains ancillary to the main residential use, though the use of the same house wholly for professional purposes would be another matter.

Medical practitioners who find themselves in doubt about their position when going to a new residence in which they propose to practise are advised to apply to the local planning authority under Section 17 of the Act for a determination whether the change which they propose to make does in fact constitute development. Under this section there is a right of appeal to the Minister against the determination by the local planning authority that the proposal in question constitutes development.

CONFERENCE OF B.M.A. REGIONAL OFFICERS

A conference of officers in charge of the Association's Regional Offices was held at B.M.A. House on March 21 under the chairmanship of the Secretary. The following Regional Officers attended: Mr. R. I. Gardner (Oxford), Mr. A. Hill (Birmingham), Miss P. M. Lee (Liverpool), Mrs. G. Maloney (Sheffield), Mr. H. W. Newman (Cambridge), Mr. R. H. Pill (Leeds), Miss F. Turnbull (Newcastle-upon-Tyne), Miss M. E. Brookes, Chief Clerk of the Association's Headquarters in Scotland, and Mr. W. A. Lee, Librarian of the Medical Institution of Liverpool, also attended by invitation. Mr. Beadle (Manchester) was unable to be present.

The Secretary opened the Conference with an outline of the purpose and functions of the Regional Offices. Dr. A. Macrae (Deputy Secretary) followed with a review of the Association's work and of the organization of the staff at Headquarters. The financial aspects of the work of the Regional Offices were briefly described by the Accountant, and a general discussion followed in which many suggestions were considered for the improvement of the Association's regional machinery. The conference was followed by a tour of Headquarters in which the visitors were shown all departments, including the Registry, Card Index Section, Typing and Duplicating Section, Empire Bureau, Medical Practices Bureau, the Library, and the principal reception rooms. It was felt that the conference was useful and ought to be repeated in the future.

British Medical Association

ANNUAL REPORT OF COUNCIL, 1948-9

Every member is asked to keep this Supplement, which contains matters referred to Divisions, until the subjects have been discussed by his Division.

PRELIMINARY

Annual Meeting, Harrogate, 1949

1. The Annual Meeting, 1949, will begin at Harrogate on Friday, June 24, under the Presidency of C. W. C. Bain, M.C., D.M., F.R.C.P., Harrogate.

All members of the Association are entitled to attend the Annual Scientific Meeting and the functions associated therewith. The Annual Representative Meeting will be held from Friday, June 24, to Tuesday, June 28.

The Council has decided as an experiment that the Scientific Sections should extend over a period of four days from Tuesday, June 28, to Friday, July 1. The Sections will meet as follows:

Anaesthetics	June 29 and 30
Anatomy and Physiology	June 28 and 29
Cardiology	June 30 and July 1
Child Health	June 29 and 30
Dermatology	June 30 and July 1
Medicine	June 28, 29, 30, and July 1
Neurology and Psychiatry	June 29 and 30
Obstetrics and Gynaecology	June 28, 29, 30, and July 1
Occupational Health	June 29 and 30
Ophthalmology	June 30 and July 1
Orthopaedics	June 28 and 29
Oto-rhino-laryngology	June 30 and July 1
Pathology and Bacteriology	June 28, 29, 30, and July 1
Preventive Medicine	June 30 and July 1
Radiology	June 28, 29, 30, and July 1
Rheumatology	June 28 and 29
Surgery	June 28, 29, 30, and July 1
Tropical Medicine	June 28 and 29

Accommodation at Harrogate

Members who intend to attend the Annual Meeting at Harrogate are advised to make early arrangements for accommodation.

Loyal Address to His Majesty

2. The Council submitted a loyal Address conveying the congratulations of the Council and of the members of the Association at home and overseas to his Majesty the King

on the occasion of the birth of a son to her Royal Highness the Princess Elizabeth.

Health Centres: Interim Report of Council

3. The Interim Report of Council on Health Centres was published in the *Supplement* of Sept. 11, 1948. This was intended to give guidance to local health authorities, local medical committees, and executive councils when considering the future provision of health centres. It is recognized that the development of health centres under the National Health Service Acts must necessarily be slow, and the Council hopes that its interim report will be a useful contribution to the study of the subject. The Council has under consideration the questions, in relation to health centres, of the position of the general-practitioner-specialist, the provision of specialist services, the provision of health centres in rural areas, and the utilization of the centres for the health education of the public. The Council will deal with these matters in its final Report.

Joint Consultative Committee of Professional Bodies

4. The Council has approved the creation of a joint consultative committee of professional bodies to facilitate exchanges of views on matters of common interest, especially on developments which may threaten to limit the exercise of their proper functions in the service of the community. The Chairman of Council and the Secretary have been appointed as the Association's representatives on the joint committee.

Deaths

5. The Council regrets to record the deaths of 524 members during the year 1948.

War Memorial

6. The Council has considered the question of a Memorial to the members of the Association who fell in the 1939-45 war, and has accepted the views of its expert advisers that such a Memorial should take the form of a Fountain erected in the Court of Honour at B.M.A. House. A limited competition will be held among three sculptors to be chosen by assessors and the Royal Society of British Sculptors will draw up rules

for the competition. The assessors to the competition will be two sculptors nominated by the Royal Society of British Sculptors, with Mr. C. H. James, R.A., F.R.I.B.A. A dedicatory inscription will be prepared by the Association, and the names of those members who fell in the war will be included in a Book of Honour. The cost of the entire Memorial will be in the region of £10,000, and an appeal will shortly be made to members of the Association for subscriptions for the Memorial.

The Secretariat

7. The Council has appointed S. J. Hadfield, M.B., B.Ch., D.R.C.O.G., as an Assistant Secretary of the Association.

Medical Practices Advisory Bureau

8. With the advent of the National Health Service the usual procedure for entry into general practice has undergone considerable modification. In the past, with the exception of a minority who "put up their plates" or secured openings through personal or family associations, introduction took place either directly in response to advertisement in the medical press or indirectly through the recognized medical agencies.

The abolition of the sale and purchase of goodwill has necessarily caused changes in established customs. A doctor wishing to enter the field of general practice as a principal must apply to an executive council for inclusion in the list for the area. The executive council, after consultation with the local medical committee, forwards applications to the Medical Practices Committee with a recommendation for acceptance or rejection. Under the Act, the Medical Practices Committee is responsible for declaring certain areas (or parts of areas) adequately served, and to refuse the admission of new principals in these cases, but, except in these "closed areas," its consent is automatic unless there is more than one applicant for a vacancy, when it has power to make a selection.

Formerly, when a doctor retired it was in his own interests to find a successor, but now executive councils are responsible for arranging for the provision of general medical services, and should a practice become vacant it is for the executive council rather than the doctor concerned, or his representatives, to see that the patients are not left without adequate care. Executive councils have a discretionary power but no statutory obligation to advertise vacancies.

It is of course still possible for a doctor to enter general practice as an assistant with a view to partnership or succession, but though the Minister has given to doctors the right to choose their own partners or assistants, the financial basis of partnerships and the transfer and adjustment of shares have been completely altered.

The Council became convinced of the need for some central machinery through which practitioners wishing to establish themselves in practice might obtain advice and information concerning suitable openings. It was clearly undesirable that the Medical Practices Committee or local medical committees, having statutory functions in connexion with the distribution of doctors, should also undertake to advise individual practitioners. It was felt that this task should be undertaken by a body which was not linked directly or indirectly with central or local government, but whose status and resources were such as would enable it to establish and maintain effective liaison with executive councils, local medical committees, and the Medical Practices Committee, and at the same time command the confidence of the profession.

The Council accordingly decided to establish as a department of the Association the Medical Practices Advisory Bureau to advise medical practitioners on all individual problems connected with entry into, or the conduct of, practice, and it was decided that the Bureau should include an appointments information service through which the introduction of locums, assistants, or partners could be effected.

The Medical Practices Advisory Bureau, under the direction of Dr. L. S. Potter, one of the Assistant Secretaries, was established at the beginning of 1949, and it was fortunate in being able to retain the services of some members of the staff of the British Medical Bureau, now in voluntary liquidation. Their experience has proved most valuable and has enabled branch offices to be established at the outset at 33, Cross Street, Manchester, and at the Scottish Office, 7, Drumsheugh Gardens,

Edinburgh. It is hoped that in the course of time other regional offices will play their part. The services of the Bureau are free of charge to members of the Association; others are expected to pay fees as a contribution to the expenses incurred.

Postgraduate Education of General Practitioners

9. In view of the satisfactory welcome given to the Report of the Association's Committee on "The Training of a Doctor" the Council has appointed a special Committee under the chairmanship of Professor Sir Henry Cohen to consider the Postgraduate Education of General Practitioners. The Committee is beginning its study from the point at which the Medical Curriculum Committee stopped—namely, at registration after a year of intern appointments—and is considering such matters as the preparation for a career in general practice, the objects of postgraduate education, and the methods and content of instruction.

National Formulary

10. In January, 1947, the Council, in conjunction with the Pharmaceutical Society of Great Britain, established a Joint Committee to compile a Standard Prescribers' Formulary suitable for use in connexion with the National Health Service and applicable to all branches of medicine. The Ministry of Health agreed to co-operate in the task by nominating representatives upon the committee, and subsequently the Service Departments were invited to appoint representatives. The committee as finally constituted was as follows:

Members	Appointed by
Professor A. E. Barnes	British Medical Association
Mr. A. Lawrence Abel	British Medical Association
Lieutenant-Colonel J. C. Brimston	War Office
Professor H. Berry	Pharmaceutical Society
Mr. B. A. Bull	Pharmaceutical Society
Sir Weldon Dalrymple-Champneys	Ministry of Health
Mr. H. Davis	Ministry of Health
Mr. P. Dobson	Pharmaceutical Society
Professor D. M. Dunlop	British Medical Association
Dr. S. A. Forbes	Insurance Acts Committee
Dr. F. Gray	British Medical Association
Dr. E. A. Gregg	British Medical Association
Dr. P. Hamill	Royal College of Physicians
Mr. D. W. Hudson	Pharmaceutical Society
Dr. D. Hunter	Royal College of Physicians
Dr. W. P. Kennedy	Ministry of Health
Mr. E. Lewis Lilley (deceased)	British Medical Association
Miss C. Mozley-Stark	Ministry of Health
Dr. A. Smith Pool	British Medical Association
Lieutenant-Colonel M. A. Rea	War Office
Surgeon Commander J. M. Rease	Admiralty
Mr. H. G. Rolfe	Pharmaceutical Society
Mr. R. H. Rowson	Pharmaceutical Society
Mr. J. W. Soulsby	Pharmaceutical Society
Professor E. J. Wayne	British Medical Association
Wing Commander C. E. G. Wickham	Air Ministry
Dr. D. J. B. Wilson	British Medical Association

Professional organizations, local medical and local pharmaceutical committees, medical staff committees of teaching hospitals, and individual experts have been consulted in connexion with the compilation of the *Formulary*, and their assistance, together with the interest and active co-operation of the Ministry and the Service Departments, has greatly facilitated the work of the committee.

The object has been to produce a *Formulary* which though comprehensive would be of convenient size to be carried in the pocket by the practitioner or pharmacist. Information which might more appropriately be sought from textbooks or works of reference has been omitted, but brief notes on certain types of preparation, such as sulphonamides, barbiturates, etc., which it was felt would be of value, have been included. Special attention has been directed to preparations in the Children's Section, in an endeavour to provide preparations, especially linctuses and mixtures, in a palatable form.

The Council believes that the *Formulary* which has been prepared will prove acceptable to the professions, and hopes that it will be useful in all branches of medicinal practice, including hospitals.

The cost of publication has been borne equally by the Association and the Pharmaceutical Society. The Ministry

has accepted the *Formulary* for use in the National Health Service, and is purchasing bulk supplies for distribution through local executive councils to medical practitioners, dentists, and pharmacists on the lists of those bodies. The *Formulary* will come into operation on May 1, 1949, and in the meantime copies are being made available first to manufacturing and retail chemists so that they may adjust their stocks of preparations. In order that they may familiarize themselves with the new *Formulary* practitioners on the lists of local executive councils will receive their copies some weeks before May 1, on which date it will replace the *N.W.F.*

The sale of individual copies to practitioners will be undertaken by the Association and to pharmacists by the Pharmaceutical Society.

Proprietary Medicines

11. The Council has appointed a special committee to consider the general problem of the advertisement and sale of proprietary medicines. It is hoped shortly to discuss the question with representatives of the Newspaper Proprietors' Association and other interested bodies.

Central War Medical Committee

12. The Council has agreed to a request from the Minister of Health that the Central Medical War Committee and the Scottish Central Medical War Committee should continue to advise him on the recruitment of medical practitioners to H.M. Forces during 1949. These committees are housed in the Association's offices in London and Edinburgh, and all their secretarial and clerical work is carried out by the Association's staff.

British Commonwealth Medical Conference

13. The Council reported last year that it was making arrangements to hold in London the Inaugural Meeting of a British Commonwealth Medical Conference. The meeting was held on Sept. 15 and 16, 1948, at B.M.A. House, and was attended by delegates from the following countries: Australia, Canada, Ceylon, Eire, Great Britain, India, New Zealand, Pakistan, South Africa, and Southern Rhodesia. The chair was taken by Sir Lionel Whitby.

It was evident that there was a general desire and need for some permanent liaison among the national medical associations or units in the countries of the British Commonwealth Nations, and the Conference drew up the following list of proposals and submitted it for approval to the associations and units represented:

1. That it is desirable to develop closer personal and professional relations, through their national medical associations or units, between the nations linked in the Commonwealth.

2. That to this end an endeavour be made to hold a Conference of Representatives of the national medical associations or units once a year.

3. That, wherever possible, the Conference be held in conjunction with a general meeting of the host association or unit.

4. That each country be invited to send two Representatives to each Conference.

5. That a pooling system be applied to the expenses of one Representative from each country.

6. That the Secretary of the host association or unit be the Secretary of the Conference of Representatives and be responsible for convening the meeting, the preparation of the agenda, and executive action resulting from decisions taken. The associations will be invited to send suggestions for the agenda to the Secretary of the meeting, and the agenda will be issued to associations at least two months before the meeting.

7. That the Conference of Representatives normally be of three days' duration.

8. That, subject to confirmation, the invitation of the Canadian Medical Association to hold the first Conference of Representatives in Saskatoon, Canada, on June 7, 8, and 9, 1949, be accepted.

9. That the President-Elect of the Canadian Medical Association, Dr. J. F. C. Anderson, be President of the first Conference.

10. That provisional acceptance be given to the holding of the Conference of Representatives for 1950 at Brisbane, Australia, and for 1951 in South Africa.

The proposals received general approval, and the next meeting of the Conference will be held in Saskatoon, Canada, in

June, 1949. All the Commonwealth countries will be represented, the British delegates being the Chairman of Council, Dr. H. Guy Dain, and the Secretary, Dr. Charles Hill. The delegates to the Conference have been invited to remain for the Annual Meeting of the Canadian Medical Association, which will take place immediately afterwards.

Visit of Sir Lionel Whitby to Canada

14. The Canadian Medical Association has invited the Council to send Sir Lionel Whitby, who is to visit the United States in the autumn of 1949, to Canada at that time in order that he may attend some or all of the Divisional Annual Meetings of the Association. The Council has eagerly accepted this opportunity of strengthening the links between this country and Canada, and Sir Lionel has agreed to extend his journey for the purpose.

World Medical Association

15. The Annual Meeting of the WMA, of which the B.M.A. is a member, was held at Geneva in September, 1948, and was attended by Dr. H. Guy Dain, Chairman of Council, and Dr. E. A. Gregg, Chairman of the Representative Body, as the British delegates, Mr. R. L. Newell and Dr. S. Wand as alternate delegates, Dr. J. A. Pridham as member of the WMA Council, and Dr. Charles Hill as Honorary Secretary. The General Assembly accepted the invitation of the B.M.A. to hold its next meeting in London and elected Dr. Charles Hill as President-Elect. The meeting will be held in October, 1949, at B.M.A. House.

NATIONAL HEALTH SERVICE

16. The new Service came into operation on July 5, 1948. It was perhaps inevitable that there should be growing-pains in a new service of such magnitude. During the first six months of the Service evidence soon began to accumulate that the burden of work for the profession, particularly paper work, had greatly increased; that in many cases income had gone down; that private practice had diminished much more than was anticipated and in many cases had virtually disappeared; and that there were doubts whether the Spens recommendations were being fully applied. In general practice the ratio of visits to consultations tended to rise, and multiple consultations became more frequent. While it is possible that some of this increase is of a temporary nature, arising out of a desire to use the Service merely because it is free, there is good reason to believe that much of it has come to stay.

17. Some of the early anomalies and difficulties found expression in a debate on the Adjournment in the House of Commons in January, 1949. In the course of that debate the Government admitted that it had completely underestimated the need for the Service, and this was borne out by some of the figures given. It was computed that 95 to 98% of the population had placed their names on doctors' lists. Rather more than 20,500 general practitioners out of an estimated total of 21,000 in England and Wales and Scotland had entered the scheme. In the first six months 75 million prescriptions for drugs and appliances were issued; over 3,400,000 patients received or were under dental treatment; over 2,500,000 people had their sight tested under the supplementary ophthalmic service, and over 3 million pairs of spectacles were supplied or were on order.

18. With the inception of the National Health Service the Association made certain adjustments in its constitution. At the Annual Representative Meeting in 1948 approval was given to the establishment of a new Central Consultants and Specialists Committee to consider and to act on all matters affecting those engaged in consultant and specialist practice and to watch the interests of consultants and specialists in relation to the new Service. The creation of this new autonomous body was accompanied by the establishment of a new regional organization of Consultants and Specialists (including Hospitals) Committees. The Insurance Acts Committee, which since its formation in 1912 has represented insurance practitioners and has been recognized by the Ministry of Health as their mouthpiece, has now been replaced by a General Medical Services Committee. At the outset this Committee was constituted on the same lines as the Insurance Acts Committee

it being left to the new committee to review its constitution (including the grouping of areas for the election of direct representatives) in the light of experience. The General Medical Services Committee acts as the Executive of the Conference of Local Medical Committees and, like the Consultants and Specialists Committee, is an autonomous body. The Public Health Committee, which includes representatives of the Society of Medical Officers of Health, considers and reports on questions relating to the Public Health Service.

In December, 1948, following the discussions of the Exploratory Committee set up some months earlier by a conference of representatives of the Royal Colleges, the Royal Scottish Corporations, and the Association, it was agreed that in the interests of consultants a Joint Committee should be established to speak for consultants with one voice. For this purpose there was established a Joint Committee with the following terms of reference:

(a) To represent consultants and specialists in the impending negotiations with the Government on matters arising out of the National Health Service Acts and the report of the Spens Committee on the Remuneration of Consultants and Specialists.

(b) To prepare and to submit for the consideration of its constituent bodies a scheme, including terms and reference, for the future work of the Committee.

19. With the formation of the Joint Committee and the establishment of the representative machinery for general practitioners and public health medical officers it was generally agreed that the time had come formally to disband the Negotiating Committee. By the end of the year that body had ceased to function, except within the limited field of the supplementary ophthalmic service. The negotiations which had been conducted over a long period by the Ophthalmic Subcommittee were left for completion by that Subcommittee.

20. During the period under review terms and conditions of service, including remuneration, have dominated the medico-political picture. Early in January the Minister responded to the General Medical Services Committee's urgent representations on behalf of rural practitioners by increasing the Mileage Fund from £1,300,000 to £2 million per annum, the increase having retrospective effect from July 5, 1948. Of the £700,000 increase, £200,000 came from the Special Inducement Fund and £500,000 was new money provided by Parliament. A few months later representations were made for an increase in the Central Practitioners Fund in the light of the report of expert economists on the betterment factor which should be applied to the Spens recommendations—expressed in pre-war money values—to convert them to present-day values. These and many other points which have been the subject of representation to the Ministry are discussed in greater detail in the appropriate sections of the Council's Report.

21. With the establishment of the Joint Committee for consultants discussions on the national scale of remuneration for consultants and specialists were begun. The Ministry's proposed terms and conditions of service for hospital medical staffs were the subject of confidential discussions between representatives of the Department and the Joint Committee. In these discussions the Joint Committee was not committing consultants and specialists but was informing the Ministry what, in its view, was likely to be acceptable or more acceptable to the profession. Following these discussions the Ministry issued its proposed terms in March and the Joint Committee has submitted them to its constituent bodies for their observations. To allow time for full discussions the interim contracts which were due to expire on March 31, 1949, were extended for a further three months.

22. In the field of public health the delay in the negotiations of revised scales of remuneration arising from the reluctance of the Local Authority Associations to participate in the National Health Service Whitley Council machinery and the action taken by the Association to refuse for publication in the *British Medical Journal* advertisements not in conformity with the Association's own recommendations are set out in the Public Health section of the report. The Association is indebted to the other leading medical journals for their co-operation in this matter.

23. Although in May, 1948, the Minister proposed that an amending Bill would deal with a number of outstanding matters the draft of the Bill has not been published at the

time this report goes to press. The points which the Minister has promised to include in the amending Bill may be summarized as follows:

1. *Legal Committee on Partnerships.*—Clarification of the position of practitioners in partnership in the light of the report of the Legal Committee. The report recommends the naming of a new appointed day applicable to those in partnership on July 5, 1948, and the establishment of a supplementary compensation fund to meet the financial obligations under partnership agreements of those in the Service but in partnership with practitioners not in the Service.

2. *Whole-time Salaried General Medical Service.*—Provision to make clear that a whole-time salaried general medical service cannot be introduced by regulations—i.e., would need a further Act of Parliament. This would include provision precluding the imposition by regulation of any universal full-time consultant service.

3. *Chairmen of Executive Councils.*—Provision for Executive Councils to have the right to select their own chairmen, after the term of office of the present chairmen expires in March next.

4. *Professional Member of the Tribunal.*—Provision to enable the professional member of the Tribunal to be one of a panel of available members and not a fixed individual—so that the member may in each case be suitable in experience and otherwise to the particular issue before the Tribunal.

5. *Costs of Local Medical Committees.*—Power to the Executive Councils, where the local practitioners agree, to cover the costs of the Local Medical Committee (by the necessary deduction from the practitioners' remuneration).

24. The points which have been or are being put forward for inclusion in the amending Bill or in amending regulations include:

1. *The Global Compensation Sum.*—Augmentation of the global compensation fund of £66 million because the number of practitioners entering the Service is substantially in excess of 17,900.

2. *Drugs and Appliances for Private Patients.*—Private patients should be enabled to obtain drugs and appliances at the public expense even though they are obtaining their medical care privately.

3. *Foreign Visitors.*—The Minister's view, with which counsel consulted by the General Medical Services Committee has agreed, is that the services provided under the National Health Service Act for "people of England and Wales" are available also for foreign visitors. In so far as the Act provides for the free treatment of foreign visitors such provisions should be excluded by the amending legislation.

4. *Medical Practices Committee and Automatic Consent.*—The law should be brought into conformity with the Minister's promise that in all areas except those where the Medical Practices Committee has decided that no more doctors are needed in the Service, the consent of that Committee will be automatic to applications for inclusion in the medical list.

5. *Block Transfer of Patients.*—The block transfer of public patients should automatically follow the selection by the Medical Practices Committee to the declared vacancy, the transfer being made to the practitioner finally selected.

6. *Appeals on Applications for Basic Salary.*—Appeals from the decision of a local executive council on applications for basic salary should be made not to the Minister but to the Medical Practices Committee.

7. *Removal of General Practitioner's Name from the Medical List.*—The necessary amendment should be made to empower local executive councils to remove from their lists practitioners no longer working in the area and no longer providing the appropriate premises.

8. *Disciplinary Procedure.*—The Service Committees and Tribunal Regulations, 1948, require among other things that any complaint by a person against a medical practitioner in respect of an alleged failure to comply with the terms of service shall be investigated by the Medical Services Committee. The regulations, however, do not contain the provision which appeared in the Medical Benefit Regulations made under the National Health Insurance Act, 1936, requiring any question arising between an insurance practitioner and a person . . . in respect of the conduct of the person while receiving treatment . . . to be investigated by the Medical Services Subcommittee. It is urged that similar provisions should be made in the disciplinary arrangements under the new Service.

9. *Membership of Local Health Authorities.*—Provision to secure that general practitioners in London should participate in vaccination and immunization schemes under Section 26(3) of the National Health Service Act and will not on that account be disqualified from membership of the local health authority. For local health authorities outside London the Ministry has expressed the view that there will be no disqualification in these circumstances.

10. *Co-option to Statutory Health Committees.*—The Minister should be empowered to require local authorities to exercise their powers of co-option to secure the inclusion on statutory health committees of medical practitioners representative of the local profession.

11. *Basic Salary.*—There should be provision to secure that the basic salary of £300 per annum is not payable to a medical practitioner where it is established that he is not needed in the area for the provision of general medical services.

12. *Representative Specialist Staff Committees.*—It should be stated in the amending Act that the Minister may recognize representative specialist staff committees (as he does Local Medical Committees) at Hospital Management Committee, Regional Hospital Board, and Board of Governors levels and that (as with the Local Medical Committees) he shall prescribe the powers and duties of these committees from time to time as necessary. The profession would like to see these committees as internal committees of the Service, the executive bodies having a duty to see that they are set up, to give them access, and to encourage full co-operation. As initial functions it should be stated that such committees should have (a) reasonable access at all times to their executive body, (b) shall, on being recognized, give prompt attention to requests from their executive body, and (c) shall be a normal and regular source from which executive bodies ask advice.

13. *Advisory Appointments Committees.*—So far as non-teaching hospitals are concerned the Advisory Appointments Committee should contain at least one or two members of the specialist staff of the hospital (assuming that there are specialists). Representative specialist committees of the hospital concerned should be given an official opportunity of expressing their views on candidates. As for teaching hospitals, Statutory Instrument No. 1416, Schedule, Part II, should be amended to read:

(Amendments in italics)

1. The Advisory Appointments Committee shall consist of ten [at present 7 members] members appointed by the Board of Governors, of whom one shall be selected by the Board to act as chairman.

2. Two of the members shall be appointed on the nomination of the university with which the hospital is associated, and at least one of such members shall be a medical practitioner, in the case of the appointment of a medical officer, or a dental practitioner, in the case of the appointment of a dental officer.

3. *Three of the members shall be appointed on the nomination of the Council of Governors of the associated medical school.*

4. *Of the five members appointed otherwise than on the nomination of the university or Council of Governors of the school, at least three shall be on the nomination of the medical committee of the hospital concerned, and shall be medical practitioners,* in the case of the appointment of a medical officer, or dental practitioner, in the case of appointment of a dental officer. One shall be a person appointed after consultation with the Regional Hospital Board of the area in which the teaching hospital is situated, or, if the hospital is situated in the area of more than one Regional Hospital Board, after consultation with both or all of such boards.*

5. *Of the members who are medical or dental practitioners, at least two shall be, or shall have been, engaged in the practice of the special branch of medicine or dentistry concerned, and at least one shall be so engaged at some other teaching hospital.*

14. *Specialist Members of Hospital Boards and Committees.*—Specialist members of executive bodies should in future be appointed after consultation with the appropriate representative specialist committee and up to one-fifth the number; Hospital Management Committees, Regional Hospital Boards, and Board of Governors to be uniform in this respect.

15. *Regulations.*—All regulations regarding specialists' services should be referred for comment to the Joint Committee before submission to Parliament.

16. *Chairmen of Hospital Boards and Committees.*—There should be provision in the amending Bill to secure that Boards of Governors and Hospital Management Committees shall elect their own chairmen.

17. *Pay-beds.*—(a) *Maximum Charges.*—The schedules of maximum charges for private in-patients and private out-patients should be abolished, if necessary by amendment of the Acts. (This will involve abolition of the schedules of the National Health Service Pay-Bed Accommodation in Hospitals, etc., Regulations, 1948, and any consequential amendment of the National Health Service Charges for Hospital Accommodation (Scotland) Regulations, 1948.) Boards of Governors and Hospital Management Committees should be given discretion to increase the overall maximum for professional service (now 75 guineas) in appropriate cases—e.g., where the stay in hospital is long or the demands on the specialist or specialists are unusually heavy.

(b) *Provision of and Charges for Private Accommodation.*—In all areas there should be an appropriate proportion of pay-beds to general beds, related to the public demand for such private accommodation. The effect of the high charges at present imposed in some private beds is to deprive a section of the population of amenities which were available to them before the introduction of the

*The part in italics at present reads "at least four shall be medical practitioners."

National Health Service. There should be a substantial reduction in the charges for private accommodation, such charges being on a uniform basis throughout the same region. Alternatively the patient should qualify for a contribution from the State towards the cost of private arrangements, such a contribution being equivalent to the cost which the State would have incurred had the patient chosen to enter public instead of private accommodation.

(c) *No-ceiling Beds.*—Boards of Governors and Hospital Management Committees should be required to provide as far as reasonably practicable that 15% of the private accommodation made available under Section 5(2) of the Act is not subject to the limitation of professional charges. (This would involve abolition of the words "not more than" preceding "15 per centum" in Regulation 9 of Pay-Bed Regulations.)

18. *Superannuation.*—(a) The option given to general practitioners to remain outside the National Health Service Superannuation Scheme and receive the Government's 8% contribution towards the maintenance of approved life insurance policies should be extended to specialists in contract with Regional Hospital Boards and Boards of Governors;

(b) The option of transferred officers to decide whether to retain the rights of alternative superannuation schemes should be extended until the final terms of service for hospital medical staff are published;

(c) Specialists practising in partnership should be entitled to have their superannuation contributions and benefits adjusted in accordance with the terms of their partnership agreement, as in the case of general practitioners;

(d) Where the services of a specialist are retained beyond the age of 65 he should be entitled to continue to make contributions to the superannuation fund, and to receive the additional benefits accruing therefrom; and

(e) Specialists who, upon retirement, are not entitled to any benefit under the Superannuation Regulations should receive the Government's 8% contribution in addition to the return of their own contributions with interest.

GENERAL MEDICAL SERVICES

Constitution of General Medical Services Committee

25. With the repeal of the National Health Insurance Act it became necessary to consider the future designation and constitution of the Insurance Acts Committee of the Association. A proposal was made that the new Committee should be constituted on lines analogous to the Central Consultants and Specialists Committee, the constitution of which was approved by the A.R.M., but it was decided that a committee based upon regional organization would not be satisfactory for general medical services which were based upon local executive council areas.

The Council decided that the new committee to take the place of the Insurance Acts Committee should be called the "General Medical Services Committee," and that for the time being its constitution should be the same as the Insurance Acts Committee. It was left to the new Committee to review its constitution, and this review has taken account of the opinion expressed by the Conference of Local Medical Committees that the mode of election and representation on the Committee should be re-examined afresh.

For some time there has been a measure of dissatisfaction with the grouping of areas for the election of direct representatives of Local Medical Committees, who form the greater part of the Committee, and the Conference asked that the grouping be revised in order that Local Medical Committees may be represented more fairly in accordance with the number of doctors in each group, having regard also to geographical considerations. This has necessitated an increase in the number of direct representatives from 27 to 33, but the increase is justified by the more equitable grouping of areas.

With one exception, no change is recommended in the composition of the rest of the Committee. The exception relates to the power of co-option. Hitherto the Committee has had power to co-opt additional members so as to secure that there should be at least four non-insurance practitioners on the Committee. This is no longer necessary, but it is felt that the Committee should still have power to co-opt not more than four members so as to ensure the representation of a particular class of experience not otherwise represented on the Committee.

These proposals will involve an amendment to the Schedule to the By-laws, and the proposed revised constitution of the Committee is set out in detail at the end of Appendix IV of this report.

Completely New — Completely Different — Today's TREATMENTS!

1949 CURRENT THERAPY

A New Annual Volume on TREATMENT

This brand new annual volume is completely different from anything ever before published—different both in concept and in content. It gives a detailed and unbiased report on the very latest treatment of every disease and disorder, from abscess to yellow fever. Each treatment described in "1949 Current Therapy" is the best treatment available today for that particular disease. Every contributor was selected by a special Board of Consultants as the authority practising the most effective treatment that can be found anywhere today for the individual disease in question.

Every single plan of therapy was written especially for this book and represents the working experience of a foremost authority, clearly describing the method he is using successfully in his own practice.

For the sake of quick reference the book is conveniently divided into 14 main sections. The first page of each section lists alphabetically all the diseases to be found therein and gives page references for each. "1949 Current Therapy" is specifically designed to give the most practical, authoritative and helpful guidance on treatment that has ever appeared in print.

By 235 contributors, selected by a Board of 12 American Authorities. Edited by HOWARD F. CONN, M.D. 550 pages. 50s.

Available shortly.

W. B. SAUNDERS COMPANY LTD.
7 GRAPE STREET, LONDON W.C.2

Ever increasing production at the Company's expanding plants makes possible a further reduction in prices of Penicillin Glaxo—for the fourth time in less than three years. The new prices bring penicillin treatment down to less than half its original cost. As from April 4th, 1949 the prices are as follows—

PENICILLIN Glaxo (freeze-dried sodium salt)		Single Vials		Boxes of 10	
		Old Price	New Price	Old Price	New Price
500 000 units	vials	4/3d	3/11d.	42/6d	38/9d.
1,000 000 units	vials	8/-	7/3d.	80/-	72/6d.
CRYSTALLINE PENICILLIN G Glaxo (sodium salt)		Single Vials		Boxes of 10	
		Old Price	New Price	Old Price	New Price
100 000 units	ampoules	—	—	22/6d	17/9d.
100,000 units	vials	—	—	25/-	20/-
200,000 units	vials	4/-	3/-	40/-	30/-
500 000 units	vials	8/6d	6/-	85/-	60/-
1,000 000 units	vials	16/-	11/-	160/-	110/-

PROCAINE PENICILLIN G		Old Price	New Price
Oily Injection Glaxo	10 cc. vials	54/-	42/-
PENICILLIN OIL-WAX SUSPENSION Glaxo	10 cc. vials	35/-	30/-
PENICILLIN OILY INJECTION B.P. Glaxo	10 cc. vials	18/-	15/-
PENICILLIN CALCIUM SALT Glaxo	1,000 000 units vials	9/-	7/6
	10 Mega bottles	80/-	70/-

Prices of the following remain unchanged

PENICILLIN Glaxo	
100 000 units, ampoules and vials	
200,000 units, vials	
PENICILLIN OINTMENT B.P. Glaxo	
PENICILLIN LOZENGES B.P. Glaxo	

All prices subject to the usual professional discount.

SEX HORMONES

When B.D.H. is specified the prescriber ensures that a product of the utmost reliability is supplied. The range of B.D.H. Sex Hormone products completely covers the field in this branch of therapeutics.

ANDROGENS

Testosterone Propionate B.D.H.
Methyl-testosterone B.D.H.

PROGESTOGENS

Progestin B.D.H. (Injection of Progesterone B.P.)
Ethisterone B.D.H.

GONADOTROPHINS

Gonan (Chorionic Gonadotrophin B.P.)
Serogan (Serum Gonadotrophin B.P.)

ŒSTROGENS

'Estigyn' (Ethinyl Œstradiol B.D.H.)
Œstroform Tablets (Tablets of Œstrone B.P.)
Œstroform Ampoules (Injection of Œstradiol Monobenzoate B.P.)

DienŒstrol B.D.H.
StilbŒstrol B.D.H.
HexŒstrol B.D.H.

The following new strengths have been added to the B.D.H. range:-

TESTOSTERONE PROPIONATE
1 ml. and 2 ml. ampoules and 10 ml. vials each containing 50 mg. per ml.

METHYL-TESTOSTERONE
tablets containing 25 mg. and 50 mg.

PROGESTIN 1 ml. ampoules containing 25 mg. per ml. and 10 ml. vials each containing 25 mg. per ml.

ETHISTERONE tablets containing 25 mg.

'ESTIGYN' Ethinyl Œstradiol tablets containing 0.01 mg.

Literature describing all B.D.H. Sex Hormones will be forwarded on request.

Remuneration of General Medical Practitioners

26 The Annual Conference of Representatives of Local Medical Committees passed the following resolution

Resolved (unanimously) That this Conference considers the present capitation fee to be grossly inadequate and calls upon the General Medical Services Committee, as a matter of the utmost urgency, to take immediate action to secure an adequate overall increase in order to relieve the serious hardship resulting from the new service

The General Medical Services Committee began the task of implementing the foregoing resolution of the Conference by instituting an inquiry, the object of which would be to show whether or to what extent the current incomes of general medical practitioners were in accordance with the main recommendation of the Spens Committee. Five areas were chosen—Lancashire, Norfolk, Bath, Halifax, and Nottinghamshire and Nottingham—and the figures obtained from these areas showed that, generally speaking, the "spread" of incomes in the 40 to 50 age group was in accordance with the Spens recommendation.

While this inquiry was being made the Committee decided that the financial position of the rural practitioners presented a problem of such grave urgency that speedy action was necessary to help them to meet their immediate commitments. Representations were made to the Ministry of Health in favour of an immediate substantial increase in the Mileage Fund, and the Ministry agreed to the Committee's recommendation that the fund should be increased from £13 to £2 million, the new money to be found from sources other than the existing Central Practitioners' Fund. £200,000 has been diverted from the Special Inducement Fund and the remaining £500,000 is a new grant from the Treasury. Thus the old mileage fund of £600,000 has been more than trebled, and the Committee was gratified at the prompt action which the Ministry took to remedy a serious situation.

There remained the question of the "betterment" factor to be applied to that part of the doctor's income which is estimated to be net income. A memorandum (Supplement Feb 19) was prepared in which the whole question of the adequacy of general practitioners' remuneration was examined in detail and conclusions were reached in the light of an expert economist's report and the changes in the cost of living of professional classes between 1939 and the end of 1948 (Supplement Jan 22). A Special Conference of Representatives of Local Medical Committees was held on March 3, when the Committee's memorandum was approved as the basis of the general practitioner case and the Committee was instructed to press the Government as a matter of urgency to adjust general practitioner remuneration on the basis of the memorandum, the adjustment to be retrospective to July 5, 1948.

On the requisition of the Council and of the prescribed number of Divisions of the B.M.A., a Special Representative Meeting was held on March 29 to consider the General Medical Services Committee's memorandum.

Basic Salary

27 Circulars issued by the Ministry of Health to executive councils show that the Minister has allowed appeals against the disapproval of applications for basic salary in cases where the applicants have only recently established themselves in the area. The effect of granting basic salary to such practitioners is to subsidize them at the expense of their professional colleagues in the area, and it is contended that this is contrary to the Minister's original intention that doctors should not be encouraged to go to areas where they are not needed.

The Minister's attitude is understood to be that having agreed with the profession's view that, up to the appointed day, every medical practitioner should have a right to choose the area in which he would enter the National Health Service, it would be impracticable to take any action which could be construed as being in conflict with that view. Subsequent to July 5 it is claimed the Minister's responsibility was to consider, on its merits, every appeal against the disallowance of a claim for basic salary, without regard to the circumstances in which the appellant came to the district before July 5.

The Minister has been asked to make provision in the proposed amending Bill or Regulations, for an appeal from the

decision of a local executive council on an application for basic salary to be made to the Medical Practices Committee and not to the Minister.

Dispensing Capitation Fee

28 The Minister's offer of a capitation fee of 6s 6d (for England and Wales), to cover the provision of medicines and appliances (except those contained in a special list) for patients who would otherwise have difficulty in obtaining them from a chemist, was accepted without prejudice to revision as the result of negotiations at a later date. Before the fee is reviewed there is to be an investigation into dispensing costs.

Vaccination and Immunization

29 Discussions with representatives of local authorities on the fees to be paid for vaccination and immunization have been adjourned until the Committee has reached agreement with the Ministry of Health on the question whether these services fall within the scope of a general practitioners agreement under the National Health Service Act.

The Committee's representations to the Ministry are to the following effect:

(i) That vaccination and immunization form no part of the practitioner's duty under his terms of service, but it is a statutory obligation of the local health authority to provide them.

(ii) That where a practitioner renders a service of this nature he should be entitled to a separate fee for the service and for any report made to the local health authority.

When agreement has been reached on the above proposals, the discussion with local authority associations will be based upon the following suggested fees:

For immunization or vaccination	
At the surgery	5s 0d per attendance
At the patient's house	7s 6d per attendance

In both cases the fee will include the report which it has been suggested should be simplified.

Provision of Medicines and Appliances for Private Patients

30 The A.R.M. in July last (Minute 50) expressed the view that those who wished to make private arrangements for medical attendance and treatment should not be debarred from obtaining necessary medicines and appliances through the National Health Service. The view of the Ministry of Health is that prescribing and dispensing are essential parts of treatment and cannot be dealt with as though they are something separate. The Ministry was asked to consider the possibility of making available, through the Hospital Service, to patients treated privately, particularly expensive and life-saving medicines (insulin and liver preparations etc.) where the cost would represent hardship to the individual, but the Ministry does not think that any workable arrangement on these lines is possible. Efforts are now being made to secure an amendment of the Act to give effect to the profession's wishes in this matter.

Certification

31 The Association has submitted a memorandum of evidence to, and its witnesses have appeared before, the Departmental Committee on Certification. It is understood that the report of the Departmental Committee is not likely to be available for some little time.

Position of General-practitioner-Specialists

32 The General Medical Services and the Central Consultants and Specialists Committees have appointed a joint sub-committee to consider questions referred to it on matters of interest to general-practitioner-specialists.

General Practitioners and Special Departments of Hospitals

33 The Ministry of Health is giving sympathetic consideration to the request for arrangements which will enable all general practitioners to be given the privilege, now enjoyed by some, of being able to obtain x-ray and pathological examinations by direct application to the hospital department concerned. The problem is said to be the practical one of increasing facilities so that the hospital departments can meet the needs of general practitioners as well as their primary duties to the hospital services.

Remuneration of Staffs of Cottage Hospitals

34. The subject-matter of the following resolutions of the 1948 A.R.M. is under discussion with representatives of the Ministry of Health:

39. *Resolved:* That the question of remuneration of general practitioners on the staff of cottage hospitals be brought to the notice of the Minister.

200. *Resolved:* That every session done by a practitioner should be paid for at full rate with no limitation of the number of sessions undertaken.

This question is linked with the terms of service for consultants and specialists, which have not yet been finally settled.

Health Centres

35. A motion (Minute 129) which was referred to the Council at the last A.R.M. deprecated any widespread establishment of health centres except after careful experiment in properly selected areas. Local medical committees have been asked to use their influence to prevent the hasty establishment of undesirable types of health centre.

Maximum Numbers on Doctors' Lists

36. No exception has been taken to a proposal by the Ministry of Health that general approval of lists in excess of the prescribed maxima should be withdrawn, and that action might be taken to bring such lists within the prescribed maxima as soon as is reasonably practicable. The Ministry has agreed, however, that no compulsory action should be taken in individual cases until all the doctors' lists in the area concerned have been cleared of duplicate names.

Stationery and Franked Envelopes for Doctors

37. The decision expressed in Minute 61 of the 1948 A.R.M. that doctors under the National Health Service should be supplied with suitable stationery and franked envelopes for the transmission of records has been discussed with the Ministry of Health. The Ministry's view is that postage is a proper charge on a doctor's practice expenses (which were taken into account in fixing their remuneration), and that arrangements for franking envelopes are not justified. The Ministry was pressed to give further consideration to the Association's request and has consulted the postal authorities, but has been unsuccessful. There does not seem to be any hope of success taking the matter further.

The Ministry was asked for assistance in securing the abolition of purchase tax on filing-cabinets for medical records. The Ministry approached the Board of Customs and Excise, whose reply was that they have no authority to remit or refund purchase tax on equipment of this nature, and that there is no possibility of obtaining such authority. Not only are there administrative difficulties in giving preferential treatment to particular classes of purchasers, since purchase tax is charged at the wholesale stage, but a concession to doctors would make it impossible to resist other claims which could be regarded as equally strong.

Medical Treatment of Overseas Visitors

38. Counsel has advised that Section 33 of the National Health Service Act, which requires an executive council to arrange for the provision of medical services for "all persons in their respective areas," means that no other qualification is required for taking advantage of the relevant arrangements than that the person is in the area to which the arrangements relate. In other words, as the Act stands overseas visitors are entitled to the benefits of the National Health Service during their stay in this country.

This is regarded as extremely unsatisfactory in spite of an assurance that it is the policy of the Government to secure reciprocal benefits for British subjects in other countries. Steps are being taken to secure an amendment of the Act on this point.

Medical Services Committee Procedure

39. The regulations governing the consideration of complaints against a medical practitioner do not provide, as the old N.H.I. Medical Benefit Regulations provided, for similar action against a patient. Although such complaints are rare it is felt that there should be provision for them under the new Service, and appropriate representations are being made to the

Ministry of Health on the subject. It is understood that an amendment of the Act will be required.

Income Tax

40. The Chief Inspector of Taxes is being asked to agree that medical practitioners who wish to do so may pay their income tax quarterly or monthly.

Assistants

41. Consideration has been given to the position of the Medical Practices Committee in relation to an application by a doctor to employ a second assistant, it being agreed that the power to approve or refuse the appointment of an assistant whose name is not on the list rests with the executive council. The General Medical Services Committee's views are: (1) that the Medical Practices Committee has no jurisdiction where an application is made to the executive council by a principal to employ a second assistant, or where the executive council propose to refuse consent to the employment of an assistant; (2) that where desired by principals the names of assistants should be included in a separate part of the lists of executive councils; and (3) that where an assistant leaves the employment of his principal his name should be removed from the list.

Training Grants for Assistants

42. The Ministry of Health scheme, providing grants to general practitioners who undertake the training of assistants, has been given provisional approval on behalf of the profession. The scheme is regarded as being in the nature of an experiment. Modification will almost certainly be necessary, and it is intended to re-examine the scheme in the near future with a view to suggesting improvements in the light of the recommendations of the Spens Report.

Certificates for Incapacity due to Pregnancy

43. The Ministry of National Insurance has agreed to the proposal that at or about the 34th week of pregnancy the doctor should be required to give only one certificate to cover the interval to the actual confinement.

Certificates for Surgical Corsets

44. Urgent representations have been made to the President of the Board of Trade that, in the interests of the profession, medical certification for surgical corsets should be abolished.

Certificates for Out-patients

45. Approval has been given to a suggestion by the Ministry of Health that Forms Med. 7 and 8, for use in connexion with long-stay patients in hospitals, might be adapted for issue to out-patients.

Consultation on Draft Regulations and Instructions

46. The Ministry of Health was asked for an assurance that the General Medical Services Committee would be consulted by the Department before statutory orders were promulgated or instructions issued by the Department to local executive councils or other bodies on matters of principle affecting doctors rendering services under Part IV of the Act. The Ministry accepts the general principle that the profession's representatives should be consulted on points of major principle involving regulations.

Specialization of General Practitioners

47. It is regarded as essential in the interests of medicine that some degree of specialization in general practice should be encouraged, and this view has been stressed during discussions with officers of the Ministry of Health. From the attitude of the Ministry of Health it would appear that there is no prospect of the general practitioner who undertakes a specialist service to his patient (unless he is also employed as a specialist in the Hospital Service) receiving a fee for the service. This view is not accepted and the matter is being pursued in further discussions with the Ministry.

Treatment in Cottage Hospitals

48. The 1948 Annual Conference expressed regret that practitioners who were not participating in the National Health Service had been excluded from rendering service, as in the past, to their own patients in local cottage hospitals. Representations

have been made to the Ministry in favour of general practitioners in the area of a hospital with an "open" staff, whether or not participating in the Service, being allowed to treat their patients in the hospital.

Dental Haemorrhages

49. The present position is that a doctor is required under his terms of service to treat a case of dental haemorrhage, whereas a dentist is entitled to claim a special fee for this service. The Ministry states that it is not legally possible to regard a doctor as a dentist's deputy in such cases. This ruling is very unsatisfactory and the Ministry has been informed that, unless this decision is modified, general medical practitioners will be advised to refuse to accept service in cases of haemorrhage arising from dental operations.

Miscarriages

50. It has been necessary to contest a ruling of the Ministry that treatment for a miscarriage should be regarded as part of the ordinary obligation of a general practitioner under his terms of service. Discussions on this question are still proceeding with the Department.

Superannuation

51. The Ministry has promised to give consideration to an amendment of Regulation 38 of the Superannuation Regulations so as to make it clear that there must be agreement between partners before an executive council can be authorized to assess superannuation contributions on the basis of shares in the partnership.

Quality of Prescription Books

52. The present unsatisfactory construction of pads of prescription forms has been taken up with the Ministry of Health.

Removal of Names from Doctors' Lists

53. The Ministry of Health has been asked to withdraw the instruction to executive councils in E.C.L.134 to remove a person's name from a doctor's list if a notice or medical card sent to the person and correctly addressed is returned through the Dead Letter Office.

Dr. E. A. Gregg

54. The Council has placed on record its appreciation of the services of Dr. E. A. Gregg as chairman of the Insurance Acts Committee since 1937 and his unflinching devotion to the interests of general medical practitioners.

CONSULTANTS AND SPECIALISTS

Introductory

55. It will be remembered that in 1948 the Committee was reconstituted on a democratically elected basis, irrespective of membership of the Association, in order that it should be truly representative of consultants and specialists throughout the country, and competent to speak for them on all matters affecting their interests. In addition Regional Committees were established in the various Regions by the consultants and specialists themselves.

The Regional Committees without exception have taken an active interest in the many problems of the moment and have kept the Central Committee fully informed of the views of consultants and specialists throughout the country.

Despite the intention of the Association that the new Committee should enjoy complete autonomy, some doubt still appears to exist as to its status in relation to the Association, and this doubt is due in some measure to the wording of Minute 71 of the Representative Body set out below:

Min. 71.—The Central Consultants and Specialists Committee shall be an autonomous body with full powers to determine policy on consulting and specialist and hospital matters and action through the administrative machinery of the Association. The decisions of the Committee shall not be subject to approval of the Council of the Representative Body *except in so far as they may affect other forms of practice or other aspects of the policy or activities of the Association.*

The Committee is satisfied that it was the intention of the Resolution only to limit its autonomy to the sphere of consultant practice, and that within that sphere it has been afforded by the Council and the Representative Body complete autonomy. To make this abundantly clear, and in order that the Committee

shall continue to enjoy the full confidence and support of consultants and specialists, the Council has decided to recommend to the Representative Body:

Recommendation: That Minute 71 of the Annual Representative Meeting, 1948, be amended to read as follows:

"The Central Consultants and Specialists Committee shall be an autonomous body with full powers to determine policy and action on consulting and specialist and hospital matters through the administrative machinery of the Association. The decisions of the Committee within that sphere shall not be subject to approval of the Council or the Representative Body."

Joint Committee with the Royal Colleges and Scottish Royal Corporations

56. With the establishment of democratically elected committees representative of various sections of the profession it became apparent some months ago that the Negotiating Committee could not appropriately continue its role as the mouth-piece of the profession in negotiations with the Minister. The General Medical Services Committee, which superseded the Insurance Acts Committee, assumed the status of the negotiating body on behalf of general practitioners, but in the sphere of consultant practice the position was more complex. The Central Consultants and Specialists Committee is the only body representative of consultants and specialists democratically elected and having the peripheral organization necessary to obtain the views of consultants and specialists generally, but notwithstanding its claims on these grounds to represent the consultant profession it is clear that on the grounds of prestige and status the Royal Colleges and Scottish Royal Corporations also have a claim to participate in any negotiations with the Minister.

Accordingly, in order that there should be one channel, and one channel only, through which the views of consultants and specialists are presented to the Minister, discussions have taken place between representatives of the Committee and of the Royal Colleges and Scottish Royal Corporations, as a result of which a Joint Committee has been established with the following terms of reference:

"(a) To represent consultants and specialists in the impending negotiations with the Government on matters arising out of the National Health Service Acts and the report of the Spens Committee on the Remuneration of Consultants and Specialists;

"(b) to prepare and to submit for the consideration of its constituent bodies a scheme, including terms of reference, for the future work of the Committee."

The Joint Committee has now taken over the work of the Negotiating Committee in the field of consultant practice. Where agreement is not reached in the Joint Committee on any proposal a constituent member of the Committee is entitled to have its view represented to the Government, provided that, before any such representation is made, a conference between representatives of the Joint Committee and the constituent body is held in an endeavour to reach agreement.

It has been agreed that the members of the Joint Committee shall represent both teaching and non-teaching interests. The composition of the Committee is as follows:

Chairman: Sir Lionel Whitby, President of the Association.

Royal College of Physicians: Lord Moran, W. G. Barnard, H. E. A. Boldero.

Royal College of Surgeons: Lord Webb-Johnson, E. F. Finch, R. L. McNeill Love.

Royal College of Obstetricians and Gynaecologists: Sir William Gilliatt, H. J. Malkin.

Royal College of Physicians, Edinburgh: J. D. S. Cameron.

Royal College of Surgeons, Edinburgh: Sir Henry Wade.

Royal Faculty of Physicians and Surgeons, Glasgow: W. R. Snodgrass.

Central Consultants and Specialists Committee: T. Rowland Hill, C. E. Kindersley, W. S. Mack, A. M. A. Moore, R. L. Newell, T. Holmes Sellers.

Specialist Spens Report

57. The Minister of Health has accepted in principle the recommendations of the Spens Committee upon the remuneration of consultants and specialists.

The Committee is of the opinion that the proposed basic salary range can be regarded as satisfactory on the basis of 1939 values, but considers that there should be no reduction in

the salary of a practitioner appointed to a specialist post before the age of 32 as suggested by the Spens Committee. The Committee welcomes the proposal that provision should be made for varying the commencing salary of practitioners appointed to their first specialist post after the age of 32, and recommends that special consideration should also be given to those who have lost seniority through service with H.M. Forces.

The Committee regards the formula of the Spens Committee for assessing the remuneration of specialists rendering part-time services as generally satisfactory provided account is taken of the liability to deputize for colleagues absent through sickness or on leave, and for emergency visits.

Merit Awards

58. It will be remembered that the Spens Committee expressed the view that an automatic incremental scale was inappropriate for the remuneration of specialists beyond a certain level and recommended that after a salary of £2,500 (1939 values) had been reached additional financial rewards should be on the basis of merit as evidenced by special contributions to medicine in the field of research or otherwise, exceptional ability, or any outstanding professional work, the awards to be made in three grades by a National Committee. Such a Committee has now been appointed by the Minister in consultation with the Royal Colleges and the Scottish Royal Corporations.

The Central Committee has given consideration to the recommendations of the Spens Committee and to possible alternative methods of rewarding specialists above the level of the basic salary range. The views of the Regional Committees have been sought, and reveal that, while there is little real objection either to the principle of merit awards or to the method of implementation recommended by the Spens Committee, so far as it applies to the most outstanding 4% of the profession, there is considerable apprehension at the fate of so large a proportion as a further 30% of the profession being left to a national committee alone to determine.

It has been suggested that, as an alternative to the merit award proposals, super-scale posts carrying higher salaries should be established, or that the basic salary range should be extended. Awards in the form of annual prizes have also been suggested. The Committee does not feel that these suggestions offer a satisfactory method of dealing with the problem, or that they would be acceptable to the majority of consultants.

It is therefore of the opinion that, while the selection of the 4% of consultants for the highest awards should be left entirely to the discretion of the National Committee, there should be some modification of the proposals of the Spens Committee for dealing with awards of the second and third categories. Thus it suggests that in each Region a committee should be established by the National Committee, in consultation with the boards of governors and regional hospital boards, of distinguished practitioners of consultant status who are not personally interested in merit awards (i.e., being already in receipt of the highest awards or retired); that these committees should select specialists in the Region for awards in the second and third categories for recommendation to the National Committee, and that awards in these categories should be made by the National Committee solely upon the recommendation of these Regional Committees, subject to a right of appeal by a rejected candidate from the decision of a Regional Committee.

The Committee also suggests that both the National and the Regional Committees should have lay chairmen chosen in consultation with the Central Consultants and Specialists Committee.

The Committee considers that individual specialists should have the right to make direct application for an award and that the decisions of the National Committee should be published from time to time, giving the names and appointment of the recipients.

Pay-beds

59. The Committee is disturbed at reports of proposals to reduce the number of private hospital beds, and at the rising costs for hospital accommodation. It is also concerned that, although the Regulations permit hospital management committees or boards of governors to set aside up to 15% of the total number of pay-beds as "no ceiling" beds, there is no obligation upon these bodies to do so.

The Committee considers it essential that sufficient hospital accommodation should be preserved for the conduct of private practice, and that the costs of maintenance should be so adjusted as to be within the means of persons who wish to obtain hospital treatment privately. It has therefore recommended to the Joint Committee that negotiations should be entered into with the Ministry as a matter of urgency with a view to securing:

- (a) the maintenance or increase of the pre-Act proportion of pay-beds; including the provision of a number of pay-beds in each hospital management committee area, and the allocation of not less than 15% of the total number of pay-beds as "no ceiling" beds;
- (b) the adoption of the grant-in-aid principle in order that patients entering pay-beds shall not be required to pay the whole cost of hospital maintenance; and the standardizing of maintenance costs so far as possible in hospital groups;
- (c) the abolition of amenity beds.

The Committee also proposes that provision should be sought in the amending Bill to secure that the setting aside of pay-bed accommodation shall be obligatory upon the Minister and not merely permissive.

Representations have been made to the Ministry for the abolition of the detailed schedules of maximum professional charges permitted to be made by specialists in respect of the treatment of private patients in "ceiling" pay-beds, contained in the Regulations made under Section 5(2) of the Act. The view of the Ministry, however, is that the wording of the Act requires the provision of such detailed schedules in the Regulations.

The Committee considers that this procedure is impracticable. The detailed schedules are full of anomalies and there are many omissions, and in view of the fact that they would constantly need revision the Committee feels that any attempt to improve them would be futile. Moreover, it is of the opinion that any classification of treatments which ignores the differing circumstances of individual cases is unsound. The Committee therefore adheres to the view that the schedules should be abolished. It raises no objection to the provision in the Regulations of an overall inclusive charge for all professional services rendered to a patient in a "ceiling" pay-bed, the actual apportionment as between individual consultants to be made locally by agreement, provided that the Ministry accepts a similar restriction in the charges for maintenance. The Committee is also prepared to accept the present maximum of 75 guineas for this purpose, provided it is limited to the treatment given to a patient during one stay in hospital not exceeding 28 days from the date of admission.

Proposed Terms of Service of Hospital Medical Staff

60. In November, 1948, the Ministry issued to the constituent members of the Joint Committee a confidential document containing the Minister's proposals regarding the permanent terms and conditions of service of hospital medical staff. Permission to disclose the contents of this document to Regional Consultants and Specialists Committees or to the consultant members of the profession was refused despite protests from the Committee. The explanation of the Ministry for this course of action was that the proposals were to be regarded as a basis for preliminary discussions in the light of which definite proposals would be issued for more general consideration.

The Joint Committee with the Royal Colleges has entered into preliminary discussions with the Ministry on the proposed terms. In so doing the Committee made it abundantly clear to the Ministry that it was not negotiating terms of service on behalf of the consultant profession, but that it was merely advising the Ministry as to the terms and conditions which might in the Committee's view prove acceptable or more acceptable to consultants and specialists. The Ministry accepted this position and agreed that definite proposals would be issued for consideration and criticism by all interested parties. The proposed terms of service of hospital medical staff were received on March 10 and published in full in the Supplement of March 19. These proposals are now under consideration by the Committee, which has in the first instance referred them to its regional committees.

The Ministry has already been informed that it is essential that individual specialists should have ample time to consider the final terms of service before being required to sign long term contracts. The delay occasioned by the course adopted by the Ministry will make this impracticable by the end of March.

and the Ministry has now extended the interim period until July 4, 1949. In the meantime specialists are advised not to enter into permanent contracts, if they are offered, until the final terms have been approved by the Committee.

Security of Tenure

61. The Committee is of the opinion that one of the most important issues to be resolved in connexion with the conditions of service of specialists, both on the transfer from the interim to the permanent arrangements and as a long-term policy, is the security of the specialist in his hospital appointment. It holds strongly to the view that, as in many hospitals and university appointments before the appointed day, the contracts offered to specialists for duties in the public service should be tenable until retiring age, only terminable with the consent of the specialist or for reasons of professional misconduct. The Committee further suggests that machinery should be established in consultation with the profession for investigating allegations of professional misconduct, and for dealing with appeals against decisions to terminate a specialist's contract.

Selection of Specialists

62. In November last boards of governors and regional hospital boards were advised by the Ministry that, pending the settlement of the final terms of service, they should proceed without delay: (a) to determine the number and types of medical staff required to carry out the work of the hospitals under their control; (b) to assess the status of existing staff with a view to deciding which officers should be offered long-term contracts in a specialist or other capacity, and the duties they should be invited to perform.

Having determined the establishments required for the future, the boards were advised to consider how far the services rendered by the existing specialist staff might need modification to provide an adequate service—e.g., whether further part-time service or additional whole-time posts were required, or whether specific duties should be continued or redistributed in the interests of efficiency. After ascertaining the needs of the hospital in this way, the boards were to proceed with the assessment of the status of the existing medical staff: in the case of boards of governors on the advice of the medical committee of the hospital, and in the case of regional hospital boards on the advice of professional committees set up for this purpose, and consisting of two general physicians, two general surgeons, one obstetrician and gynaecologist, together with two specialists in the specialty under review.

The Ministry made it clear in its instructions that no general criteria of specialist status could be laid down, and that the determination of status could not depend solely upon the possession of higher qualifications or the exclusive practice of a specialty, but must take account of the actual experience of the practitioner. In making the assessment the professional committees were directed to have regard to the views of the medical committees of the hospitals concerned and, in appropriate cases, of the local medical committee and the local health authority.

The Committee feels that the direction to consult with hospital medical committees, although of considerable importance, does not sufficiently safeguard the interests of individual practitioners. It has therefore proposed that a central professional committee should be established to deal with appeals against the decision of the Assessments Committee or of the boards.

The Committee has made proposals to secure that where a general practitioner who also practises a specialty has acquired the necessary skill and experience to justify recognition as a specialist he should have the same security of tenure in his appointment and receive the same remuneration as those who practise a specialty exclusively, and, further, that he should be afforded a sufficient amount of specialist service to enable him to maintain his efficiency.

Only when the review referred to above has been completed and the permanent rates of remuneration are known can long-term contracts be offered. Boards have been instructed, however, that subject to the needs of the Service, consideration should be given to the circumstances and preferences of the individual specialist in offering contracts, and that opportunities to transfer from whole-time or part-time, or vice versa, should so far as possible be given.

Medical Advisory Committees

63. The Committee considers that the present position regarding the establishment and recognition of medical advisory committees at various levels leaves much to be desired. It is anxious that the members of hospital staffs should continue, as under the voluntary hospital system, to make an effective contribution to the organization of the hospital services. It feels that this can only be secured through the machinery of medical advisory committees, associated with the boards of governors and regional hospital boards and hospital management committees, freely elected by and representative of the medical staffs of the hospitals affected. It considers such committees should have statutory recognition in the same way as the local medical committee.

Advisory Appointments Committees

64. The Appointment of Specialists Regulations, which require the appointment of practitioners to hospital specialist posts to be made by boards of governors and regional hospital boards on the advice of advisory committees, make no provision for the representation of the medical staffs of the hospitals concerned upon these committees, and they have therefore no official voice in the appointment of their future colleagues.

The Committee proposes that the Ministry should be urged to amend the regulations to provide that at least two of the medical members of these committees should be nominated from among the members of the senior medical staff of the hospital in which the vacancy exists, and that the medical committee of the hospital should have an opportunity of submitting its views upon the candidates for the appointment. It also proposes that the advisory committee should include a specialist or specialists nominated by an organization recognized by the board of governors or the regional hospital board as being representative of the branch of specialists concerned.

Mileage

65. The Committee considers that the mileage allowances payable to specialists are completely inadequate, and it has obtained from the A.A. and R.A.C. estimates of the cost of maintaining and running cars of varying horse-power over different annual mileages which support this view. The Committee is using these figures in pressing its claim with the Ministry that the allowances should be substantially increased.

The Committee has recommended that where full-time salaried specialists are under a continuing liability to travel outside their main hospital in the course of their duties they should be entitled to claim mileage in respect of journeys from their homes to the hospitals, and that mileage should be paid to all whole-time officers for journeys from their homes to hospitals on emergency visits, and between hospitals.

Superannuation

66. The Committee has considered a number of matters affecting the superannuation rights of consultants and specialists.

Representations have been made to the Ministry that an option to remain outside the N.H.S. Superannuation Scheme and to receive the Government's 8% contribution towards the maintenance of approved insurance policies should be granted to specialists in the same way as to general practitioners. This option is of most value to the senior practitioner who, already heavily committed for life insurance, is unable to qualify for a pension.

Transferred officers had the option within the first three months of the Service to decide whether to retain the rights of superannuation schemes to which they were contributing before July 5 or to transfer to the N.H.S. scheme. Representations have been made that this option should be extended until the practitioners concerned can consider the position adequately in the light of the permanent terms.

The Minister has rejected both of these requests, and the Committee has decided to renew its representations.

The Committee has also decided that the following points should be raised with the Ministry (a) that specialists practising in partnership should be entitled to have their superannuation contributions and benefits adjusted on the basis of their partnership shares, as in the case of general practitioners; (b) that where the services of a specialist are retained beyond the age of

65 he should be entitled to continue to make contributions to the superannuation fund, and to receive the additional benefits accruing therefrom; and (c) that specialists who upon retirement are not entitled to any benefit under the Superannuation Regulations should receive the Government's 8% contribution in addition to the return of their own contributions with interest.

Hardship Caused by Interim Terms

67. In November last the Ministry announced that where it was clear, by reason of the seniority of a specialist performing eight or more sessions that his eventual remuneration would be substantially higher than the £1,600 laid down in the interim arrangements, and where meanwhile the temporary limitation involved him in financial hardship, he might ask the Regional Hospital Board or Board of Governors for an increase in the interim payment.

Representations were accordingly put forward that a similar concession should be made in the case of specialists of senior status who were performing less than eight sessions per week, but without success.

Financial Position of Junior Hospital Staff

68. Some months ago the attention of the Ministry was drawn to the acute financial hardships caused to registrars and junior house officers by reason of the deduction of superannuation and national insurance contributions from salaries already grossly inadequate. The Ministry had stated that it hoped the introduction of the permanent terms would not be long delayed and that for this reason it was anxious to avoid any temporary adjustment.

In view of the extension of the interim period the Ministry has again been urged to adjust the salaries of house officers provisionally and with retrospective effect to July 5, 1948, on the basis of the proposed new salary scales. It is regretted that despite repeated representations no action has yet been taken by the Department to mitigate the financial hardship to the classes of practitioner referred to in this paragraph.

Lectures to and Examination of Nurses

69. With a view to securing a uniform scale of payment to specialists for undertaking lectures to and the examination of nursing staff, the Committee has recommended to the Joint Committee that the following fees be accepted as a basis for negotiation with the Ministry: Each lecture, £3 3s.; examinations, 10s. 6d. per candidate, with a reduction of 33% where no viva voce examination is required.

Domiciliary Visits

70. Repeated representations have been made to the Ministry for the abolition of the limitation upon payment for domiciliary visits, but the Ministry has consistently refused to waive the maximum quarterly payment, although it states that in comparatively few cases has the maximum been exceeded.

Pending the introduction of the permanent terms specialists are advised to keep a careful record of all domiciliary visits which they make.

Domiciliary Visits in Nursing-homes

71. The domiciliary visiting arrangements do not extend to patients in private nursing-homes, except in the case of patients permanently resident in such homes—e.g., elderly infirm persons in a home for aged people. The services of an Emergency Obstetric Unit (including the services of a specialist) are, however, available in a nursing-home as elsewhere. Having regard to the special position of maternity cases, where the patient often receives treatment in a nursing-home because of the unsuitability of her home or the lack of hospital accommodation, the Committee has recommended that domiciliary visits should be permitted to patients in nursing-homes in emergency obstetric and neonatal cases.

Trainee Specialists

72. The Committee is recommending that hospital management committees should consult with the medical staff committee of the hospital (or with the medical staff where there is no staff committee) in appointing practitioners to trainee specialist posts.

It also proposes that appropriate machinery should be established to maintain adequate standards in the training and appointment of trainee specialists, and that this should be the responsibility of the Regional Hospital Board.

Fees for Medico-Legal and Other Work

73. There are a number of services carried out by specialists in connexion with their hospital duties which in the past have been regarded as being undertaken in a personal capacity, the fees being retained by the specialist. These include medico-legal work, the examination of intending immigrants and blind persons, special reports for outside bodies, and lectures to and examination of nurses.

The view of the Committee is that the fees for services of this nature should continue to be retained by the individual specialist irrespective of whether he is a whole-time or a part-time officer. The Ministry's proposals on the subject are included in the proposed terms of service now published, and the matter will now receive further consideration by the Committee.

Candidates for Hospital Appointments

74. Representations have been made to the Ministry that candidates attending for interview in connexion with hospital appointments should receive subsistence allowance in addition to their railway fares in cases where they are necessarily detained away from their homes overnight.

Supplementary Ophthalmic Service

74a. Shortly after the introduction of the National Health Service the Ministry of Health, being perturbed at the total fees paid to practitioners participating in the Supplementary Ophthalmic Service, collected information from a number of local executive councils which led it to believe that the original estimate on which the fee of £1 11s. 6d. had been based—namely, an examination lasting on the average half an hour—was incorrect.

The Ministry therefore proposed that there should be an immediate provisional reduction in the fee, to be followed by an impartial and comprehensive factual inquiry into the timing of ophthalmic examinations, in the light of which the fee would again be reviewed. The Ministry was persuaded at discussions in December, 1948, that the first step should be to carry out the proposed inquiry. The preliminary arrangements for an inquiry broke down, and on these grounds the Ministry again proposed at a further meeting in February, 1949, that the fee should be reduced immediately, further steps to carry out a full and impartial inquiry being made as soon as practicable.

The Ministry was again urged to take no action to modify the fee until the original estimate on which the fee had been based had been verified. On Feb. 14, however, the Minister announced that as from April 1 the fee would be provisionally reduced to £1 5s. on the basis of an average timing of 24 minutes, with an assurance that if a subsequent investigation revealed that the reduction was not fully justified an appropriate adjustment would be made in the fee eventually fixed.

The Ministry has now intimated that it has been able to make fresh arrangements for an inquiry, and has invited the Association, jointly with the Faculty of Ophthalmologists, to nominate representatives to a working party in association with the statistician who will carry out the investigation.

Throughout the discussions it has been maintained that a factual inquiry into the time actually taken by ophthalmic practitioners in the examination of their patients should precede any question of a reduction in the fee, and a protest was made to the Minister at the course adopted, particularly in view of the fact that arrangements for such an inquiry were already in hand. Nevertheless, bearing in mind the assurance that the reduction is provisional, and that an appropriate adjustment will be made if the inquiry reveals the reduction not to be fully justified, the Council proposes to co-operate in the inquiry, and, with the concurrence of the Faculty, has nominated representatives to the working party.

Central List of Ophthalmic Medical Practitioners

The Executive Council Regulations, 1947, provide for the establishment of a committee to advise the Minister of Health

to the practitioners who have the "prescribed qualifications" entitling them to participate in the Supplementary ophthalmic Service.

The Minister has approved a committee of seven medical practitioners nominated jointly by the Association and the Ministry, and this committee has been housed in B.M.A. House, and its secretarial and clerical work has been undertaken by the Association's staff. During the past eight months the committee has dealt with the applications of well over 30 practitioners.

PRIVATE PRACTICE

Examination of Recruits to the Territorial Army

5. The Annual Representative Meeting (Min. 91) instructed the Council to press for the retention or re-establishment of military medical boards for the examination of recruits for the Territorial Army. The Council had already urged the War Office to adopt the procedure, but the Department, while agreeing that this method would be preferable, held that it would be impracticable to put it into effect. The Council thereupon pressed that the fee payable to individual practitioners for carrying out the examinations be increased from 5s. to 15s. a case, and that the overriding maxima be abolished. The Department agreed to increase the fee to 10s. 6d., but was unwilling to make any concession on the overriding maxima. The Council is not satisfied with the present position: the fees are totally inadequate in view of the nature of the examination required, and there appears to be no practical difficulty in the way of arranging for the examination of the great majority of recruits for the Territorial Army to be carried out by medical boards.

These views have been communicated to the Department, which has been urged to establish medical boards without delay. There are here exceptional reasons it is impracticable for the recruit to be examined by a medical board the Council has urged that a fee of £1 11s. 6d. should be paid to the examining practitioner.

Mileage Payments to Members of Medical Boards

76. Discussions have taken place with representatives of the Ministries of Labour, Pensions, and National Insurance on the subject of the payment of mileage to members of medical boards. The Departments have for a long time resisted these payments, claiming that the sessional fees have always been recognized as an inclusive payment. This view is not accepted by the Council. A more difficult circumstance to overcome, however, arises from the Ministries' practice of "spreading" medical board work among members of the profession without regard to proximity to the boarding centre, and the Departments now state that if mileage is to be introduced it will be necessary to "prune" the panels of medical board members. The Council recognizes this difficulty while still holding to the principle that mileage should be paid. To meet the position it is suggested that there should be a mileage allowance limited, say, £1. This it is felt would compensate the busy practitioner, who, in general, would be within a reasonable distance of the boarding centre, without depriving his colleagues at a greater distance—to whom the time factor could not be of any significant importance—from sharing in the work.

The Departments have now indicated that they are prepared to pay mileage allowance at the rate of 1s. a mile each way for every mile outside a radius of two miles, subject to a maximum of 20s. for each return journey and subject, also, to the payment of a lower sessional fee where arrangements are made for less than three cases to attend the boards. The proposals of the Departments have been accepted by the Council.

Recruiting Medical Boards

77. The Annual Representative Meeting referred to the Council a motion by Gateshead that, in view of the recent introduction of the Pulheims system of classification, a considerable reduction should be made in the number of candidates called for examination by recruiting medical boards.

The Council ascertained from the Department that National Service medical boards are expected to examine 20 men or 15

women during a 2½-hour session. These numbers were temporarily reduced while the boards were gaining sufficient experience in the new procedure, but it now appears that they can be dealt with without undue pressure during the prescribed session.

The Council has decided that unless further complaints are received no action be taken to obtain a reduction in the numbers of candidates called for examinations by National Service medical boards.

Future Designation of the General Practice Committee

78. In the Council's view it is desirable that the name of the General Practice Committee should be changed now that a General Medical Services Committee has been set up to deal with all questions affecting general practitioners under the National Health Service Acts. The Council proposes that the General Practice Committee should be renamed the Private Practice Committee and that it should consider questions in the field of private practice not specifically referred to other committees. The proposed amendment to the Schedule to the By-laws to give effect to this change appears in Appendix IV of this Report.

Remuneration of Civilian Medical Practitioners Employed by Service Departments

79. The War Office has agreed that the revised rates of remuneration payable to civilian practitioners engaged on whole- and part-time duties should be applied retrospectively to April 1, 1947. The Air Ministry has also revised the fees payable to civilian practitioners to bring them into line with those agreed with the War Office.

The Council has stressed to the Air Ministry that the fee for the re-examination of regular and non-regular Air Force personnel for fitness to fly, where carried out by civilian practitioners on contract with the Department, should be increased from 9s. 6d. to £1 11s. 6d. The Department has now increased the fee to £1 1s. with mileage at the rate of 1s. per mile beyond a radius of two miles, but the Council is continuing to press for a fee of £1 11s. 6d.

Advisory Panels under the Disabled Persons (Employment) Act, 1944

80. Following representations from the Council, the Ministry of Labour offered to increase the sessional remuneration of members of Advisory Panels established under the Disabled Persons (Employment) Act, 1944, from £1 11s. 6d. per session to £2 5s. for sessions of 1½ to 2½ hours, and to introduce a reduced sessional fee of £1 10s. for sessions with a normal duration of less than 1½ hours. The Council informed the Ministry that the fee of £1 10s. should be restricted to sessions of not more than one hour, and that if the Ministry wished to make provision for sessions of 1 to 1½ hours it should pay a fee of £1 15s. therefor. The Department has now agreed to pay a fee of £1 15s. for a session of less than 1½ hours, and has also agreed to pay a mileage allowance at the rate of 1s. a mile each way outside a radius of two miles, subject to a maximum allowance of 20s. for each return journey.

Independent Referees of the Ministry of Labour

81. Following negotiations with the Ministry of Labour the Department has increased the fee payable to independent referees for reports upon persons referred for examination with a view to determining fitness for a particular employment from 5s. in undisputed cases and 10s. 6d. in disputed cases to 12s. 6d. in either case, with effect from Aug. 1, 1948.

It has also been agreed with the Ministry of National Insurance that a fee of 12s. 6d., plus travelling expenses where indicated, should be paid for the completion of a similar form in cases where there is doubt as to the capability of a claimant to unemployment benefit and the claimant is referred to a medical referee for medical examination.

Remuneration of Medical Officers at Government Training Centres

82. After negotiations with the Ministry of Labour the following revised rates of remuneration have been agreed for

medical officers at Government Training Centres, including those at which rehabilitation units are established, with retrospective effect to Jan. 1, 1948:

Attendance up to $\frac{1}{2}$ hour	£1 0s.
over $\frac{1}{2}$ hour up to 1 hour	£1 10s.
over 1 hour up to $1\frac{1}{2}$ hours	£1 15s.
over $1\frac{1}{2}$ hours up to $2\frac{1}{2}$ hours	£2 5s.
over $2\frac{1}{2}$ hours up to 3 hours	£2 15s.

Allowances to Medical Witnesses in Criminal Cases

83. The Home Secretary has issued new regulations amending the maximum allowances payable to medical witnesses appearing to give evidence in criminal cases. The regulations embody the recommendations of the Departmental Committee and provide for a maximum allowance of £5 per day, subject to not more than half this sum being payable for an attendance of less than four hours unless the witness appears in more than one case on the same occasion. The regulations provide for the first time for the payment of a night allowance in cases where the witness is necessarily detained away from his home overnight.

Experience has already shown that allowances are being offered to medical witnesses which are considerably below the maximum laid down in the regulations. Further, no allowance is being paid where the practitioner giving evidence holds a full-time salaried appointment. The Council is discussing both questions with the Home Office.

Doctor's Signs on Cars

84. Further consideration has been given to the question of the use of a distinctive sign to indicate membership of the Association, and specimen badges have been inspected. The Council is advised that even if a special badge were used no official recognition could be given, and the Home Office would not instruct the police to give any preferential treatment to doctors displaying the badge. The Council is of the opinion that no action should be taken to encourage the use by members of the Association of a distinctive motor badge.

Fees for First-aid Lectures

85. The St. John Ambulance Association and the British Red Cross have increased the fee for lectures in first-aid given by members of the profession from £1 1s. to £1 11s. 6d. in accordance with the decision of the Representative Body in 1948. The fees for examinations have also been increased from £1 1s. per class of 20 to £1 1s. per class of 12, with an additional 1s. 6d. for each candidate in excess of 12. The St. John Ambulance Association has also adopted the mileage rate of 1s. per mile (each way) beyond two miles.

Police Surgeons

86. The contracts of certain Metropolitan divisional police surgeons who did not enter the National Health Service were terminated at the appointed day on the ground that they would be unable to undertake the treatment of police officers.

A strong protest was addressed to the Home Office on the subject of this discrimination against practitioners remaining in private practice, and a question has also been raised in the House of Commons. The attitude of the Department was that in future the title of divisional surgeon would be an honorary one attaching to those practitioners who indicated that they were prepared to accept police officers as patients under the National Health Service and who were also prepared to carry out "station calls" at the request of the police. It has been pointed out to the Department, however, that it is no longer the duty of the police surgeon to render treatment, and that there is no justification for debarring those practitioners who have hitherto efficiently undertaken services required by the police authority from continuing to do so merely on the ground that they are not eligible to treat police officers as public patients.

The matter has been vigorously pursued with the Department, and it is understood that the practitioners concerned will not be debarred from having their names included in the lists of available doctors maintained at police stations in the Metropolitan area.

Life Insurance Examinations—Supplementary Reports

87. Agreement was reached with the Life Offices Association some time ago that the fees payable for life insurance examinations should be £1 11s. 6d. where the standard form of report was required and 10s. 6d. where the report was on the short form normally used for policies of less than £300. A number of practitioners subsequently sought guidance as to the fee, if any, which should be payable for additional reports which some companies required from time to time to supplement the information contained in the original report.

After discussions with the Life Offices Association the Council has agreed that, except where the additional information is required in consequence of an omission in the original report or to elucidate statements made therein, a fee shall be payable in such cases, the amount to be left for arrangement between the practitioner and the company on the understanding that no "token" fee shall be offered and that normally the fee shall be not less than 10s. 6d.

National Coal Board

88. The National Coal Board has been asked to recognize the Association as the representative body with whom it should discuss the salaries and conditions of service of the medical officers in its service. The Board has now given an undertaking that as a general principle it is prepared to consult the Association on the matters referred to and that the Association can, if it at any time desires to make representations on the salaries and conditions of service of the Board's medical officers, approach representatives of the Board on such matters. The Board has asked for comments on suggested scales for its medical officers, and this question is under consideration by the Council.

Examination of Candidates for Civil Service Appointments

89. Since the inception of the Treasury Medical Service the Council has urged the Treasury to raise the fee for this examination from £1 1s. to £1 11s. 6d. (the fee for a full life insurance examination). The Treasury agreed to increase the fee to 25s., and the Council has decided to accept this fee for a trial period of one year.

Examination of Candidates for Appointment under Regional Boards, Local Executive Councils, etc.

90. The Ministry of Health has been urged to standardize the fee for the examination of candidates for employment with regional hospital boards and executive councils. The Department stated that although no medical examination is required for such appointments under the Superannuation Regulations, the Minister considered it desirable that such an examination should be made a condition of permanent appointment.

The certificate which the examining doctor is asked to complete is that the candidate is "free from any physical defect or disease which now impairs his capacity satisfactorily to undertake the duties of the post for which he is a candidate." The Council considers the fee of one guinea to be appropriate for an examination and report in the form described.

Medical Officers to Public Schools and Private Boarding Schools

91. In the large majority of cases public schools and private boarding schools have made arrangements for the treatment of scholars under the National Health Service, the scholars being placed on the public list of the school medical officer. The duties of these practitioners normally include services which are outside the range of service under the National Health Service—e.g., the examination of scholars and the giving of advice on school hygiene, etc.—and for which the practitioner is not debarred from receiving a fee. The Council recommends that the remuneration for such duties should be not less than £1 1s. per scholar per annum.

Medical Officers to Approved Schools

92. The Council has discussed with the Home Office the remuneration of medical officers of approved schools.

Apart from actual medical treatment covered by capitation payments under the National Health Service, the work includes

GREATER STABILITY
with
'AVLON'
brand
CRYSTALLINE
PENICILLIN POTASSIUM SALT

Pure crystalline *potassium* salt of penicillin — the most stable penicillin yet produced — is now available in Great Britain for the first time.

Manufactured by Imperial Chemical [Pharmaceuticals] Ltd., this new potassium salt is much less hygroscopic than the sodium derivative, and can be exposed to a moist atmosphere for long periods without deterioration. It is particularly suitable for use in tropical climates.

*'Avlon' Crystalline Penicillin Potassium
Salt is issued in vials of 0.1, 0.2, 0.5 and
1 mega unit.*

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD., DAGENHAM

'sacred disease'

Hippocrates, 'Father of Medicine,' was centuries ahead of his time when he insisted against the opinion of all orthodox Greek medicine that 'sacred disease' (Epilepsy) resulted from natural causes and was not due to possession by the gods.

Even in the present scientific age there is much about epilepsy that remains a mystery; but in 1938 an important

advance was made by the discovery of 'Epanutin,' a drug that enables many epileptics to live a normal life, and, in practically all cases of 'grand mal,' reduces the number of fits to a manageable proportion.

'EPANUTIN'

'Epanutin' (the original phenytoin sodium) is a powerful anti-convulsant with little or no hypnotic effect.

Available in bottles of 100 and 1000 1½-grain and ½-grain capsules.

KAYLENE SALINE

is a combination of the toxin adsorbent Kaylene and the laxative salts necessary for carrying it through the intestinal tract

It is slightly effervescent and sweeps the intestinal tract free from toxin waste. It operates in the stomach, duodenum, small intestine and colon, and is most effective when administered in the early morning a full half-hour before breakfast. Kaylene Saline is widely prescribed in the treatment of toxic conditions which are associated with constipation.

Formula: Kaylene (Colloidal Kaolin) 60.579%, Saline 39.421%

Samples and literature on request

KAYLENE LIMITED

WATERLOO ROAD, LONDON, N.W.2

a visit to the school at least once a week, examination of every pupil on admission and discharge, the quarterly inspection of the whole school, and the general supervision of the health of the pupils. The Department has suggested that in computing the salary for the quarter the number of pupils should be considered as being the nearest ten above the average number of the school register for that quarter, and should provisionally be at the rate of 15s. per annum per pupil for the first 100 pupils, 13s. per pupil for the second 100 pupils, and 9s. per pupil for the third 100, with a minimum salary of £30 per annum for 40 pupils or less.

This mode of computing the salary would make for convenience in meeting the considerable fluctuation that sometimes occurs in the number of pupils on the school register. In addition the medical officers to the approved schools would receive the capitation fees under the National Health Service Act and the fees for notifying the immunization of pupils against diphtheria. The Council regards this arrangement as satisfactory.

Locums for Representatives at Meetings

93. The Annual Representative Meeting (Minute 199) suggested that through the columns of the *Journal* or in other ways members of the Association should be invited to volunteer to do part of the professional work of representatives during *B.M.A. meetings*. The Council has given publicity in the *Journal* to this most useful suggestion.

Dr. J. W. Bone

94. The Council placed on record its great appreciation of the services of Dr. J. W. Bone, who as a member, Chairman, and latterly as Treasurer of the Association, served on the Medico-Political and General Practice Committees for a total of more than twenty-five years.

Doctors' Cars

95. The Council has considered Minutes 62 and 86 of the A.R.M., 1948:

62. Proposed by BUCKINGHAMSHIRE: That, in view of the difficulty of transport experienced by doctors, priorities for cars be given to those who apply to, and satisfy, their Executive Councils as to their need.

RESOLVED: That this matter be referred to the Council.

86. RESOLVED: That this meeting is not satisfied that there is any improvement in the position in regard to the obtaining of doctors' cars, and urges the Council to secure definite priority, with specific preference to doctors with a high annual mileage; and to advise the profession from time to time what makes and models of new cars are available for the home market.

The Council is satisfied that members of the profession receive a measure of priority in securing new cars and that everything possible is being done by the Association not only to remind motor manufacturers of their obligations in this matter but also to assist individual practitioners. Recently, as a result of co-operation by the Ministries of Health and Supply, an attempt has been made by the trade to reduce the accumulation of orders outstanding for considerable periods. It is hoped, by this means, to make more effective the normal procedure for allocation priority. Responsibility for giving preferential delivery to doctors, has been accepted by the motor manufacturers in cases where a practitioner has difficulty in fulfilling his professional commitments for lack of reliable transport. The role of the Association through its central or local machinery is to appeal and advise on the grounds of urgency of professional need; it cannot, of course, express an opinion as to the condition of doctors' old cars.

The Council does not consider it practicable to advise members regarding the models most readily available, as the situation changes from time to time, and it feels that any such action would not be supported by the manufacturers.

OCCUPATIONAL HEALTH

Duties of and Ethical Rules for Industrial Medical Officers

96. The Representative Body in 1937 approved a statement of the Duties of and Ethical Rules for Industrial Medical

Officers. The Council has reviewed this statement in the light of experience, and now submits, in Appendix II, a revised statement for approval. In Appendix III the existing version is given for comparison.

Recommendation: That the revised statement of the Duties of and Ethical Rules for Industrial Medical Officers be approved.

Occupational Health Service

97. The Council understands that certain Government Departments are now investigating the question of a comprehensive Occupational Health Service, and it is therefore preparing for approval by the Representative Body an interim report on this subject in which proposals will be made as to the broad framework of such a service.

National Dock Labour Board

98. The National Dock Labour Board has established a medical service at the Avonmouth Docks, and two medical officers employed by the Bristol Corporation have been allowed by the Corporation to make a personal contract with the Board to act as medical officers to the Docks while continuing to carry out the same work as they performed in the past as whole-time public health medical officers. The Council represented to the National Dock Labour Board that these appointments should be advertised in the medical press, but the Board did not accept this suggestion.

The Council had understood that the service would be confined to a first-aid and accident service for dock-workers, but it now appears that it is not so restricted and that it is available to other persons in the area of the Docks. The Council is concerned about the possibilities of encroachment on the work of local practitioners, and has decided to refuse publication of any future advertisement of medical appointments under the National Dock Labour Board unless a satisfactory assurance is received as to the scope of the work to be undertaken. The Council is opposed in principle to public health medical officers being allowed to undertake such extraneous duties, and is considering what further action can be taken in the matter.

The National Insurance (Industrial Injuries) Act, 1946

99. The Council has considered the provisions of this Act in the light of an exposition of the Act kindly given by the Chief Medical Officer to the Ministry of National Insurance. The Act has replaced the Workmen's Compensation Act and has altered the whole approach to the subject of compensation for industrial injury. Compensation is assessed on the basis of loss of faculty, not loss of earnings; and to a large extent the provision of injury and disablement benefits by the State as a social service is likely to remove the subject from the arena of litigation, although an injured workman may still sue his employers at common law if he can prove negligence.

A workman totally incapacitated by an industrial accident or a prescribed industrial disease receives injury benefit at the rate of 45s. a week for a maximum period of 26 weeks. This rate is much higher than that of the ordinary sickness benefit provided under the National Insurance Act. If at the end of 26 weeks there is any residual permanent disablement the case is referred to a medical board for assessment for pension, the loss of faculty being assessed on a percentage basis.

The initial diagnosis in cases of suggested prescribed industrial disease is obtained by referring the claimant for examination by an examining medical practitioner, and the Appointed Factory Doctors have been invited to undertake this work. The medical board consists of not less than two doctors engaged in active practice. There is a right of appeal from the findings of the board to a medical appeal tribunal composed of an eminent lawyer as chairman and two medical members of consultant rank. The tribunal is the final arbiter. The pneumoconiosis problem is dealt with separately by means of boarding panels of whole-time medical officers.

The Council is considering certain problems connected with the diagnosis of industrial dermatitis, and hopes to have an early opportunity of discussing these problems with the Ministry of National Insurance.

Cabinet Committee on Industrial Productivity

100. At the Annual Meeting of the Association in 1948 Sir George Schuster, Chairman of the Panel on Human Factors of the Cabinet Committee on Industrial Productivity, was the principal speaker at the first meeting of the Section of Occupational Health. He opened a discussion on the contribution that the medical profession can make to industrial productivity through human relations. He appealed for the help of the profession in the work of his Panel and seemed anxious to make contact with industrial medical officers.

Problems of mutual interest have been discussed with Sir George Schuster and members of his Panel, and the Council hopes that opportunities of fruitful co-operation will be found.

Joint Councils on Industrial Medicine

101. One of the developments in the field of Occupational Health is the establishment in various parts of the country of Joint Councils on Industrial Medicine. At the present time there are seven such Councils in existence and in four other areas the establishment of Joint Councils is under consideration. These Councils, which are advisory in character, consist of representatives of employers, employees, and the medical profession. They aim to discuss problems of common interest associated with industrial health, and experience has shown that their deliberations have tended to promote a better understanding between all concerned.

As a result of an approach to the Trades Union Congress, the General Council of that body has approved in principle the establishment of Joint Councils, subject to discussion of their precise functions and organization. The support of the British Employers Confederation in the establishment of Joint Councils is now being sought.

Prescribing by Industrial Medical Officers

102. In certain areas where the majority of the doctors are part-time medical officers to local factories it has been found that during the sessions at the factories the medical officer has been asked to see another doctor's patient, who obviously should go home and would benefit from a prescription being given that day. It has been suggested that the industrial medical officer should prescribe for such a patient and write a brief note to the patient's doctor, to be handed to him when he visits the next day. The Council has examined this suggestion and considers that it is undesirable that industrial medical officers should prescribe in these circumstances.

Nurses in Industry

103. The Council is considering the training of nurses for industry and the problem of effecting economies in the use of State-registered nurses in this field. It believes that wider use, under supervision, of enrolled nurses and specially trained first-aid attendants could reduce the claims of industry for State-registered nurses without lowering the standards of service.

NURSING

104. The Council has considered certain proposals for nursing legislation submitted by the Ministry of Health. It found some of these proposals unacceptable, and its constructive criticisms were communicated to the Ministry and were discussed with representatives of the Ministry at a conference held in October, 1948.

Revised proposals were later submitted for comment, and the Council again suggested a number of amendments. The proposals are confidential and cannot be disclosed at present. It is understood, however, that they will be incorporated in a Bill which will shortly be presented to Parliament, and the Council hopes to be able to make a further statement on the subject in its Supplementary Report.

PUBLIC HEALTH

Salaries in the Public Health Service

105. The recommendations for permanent scales of remuneration for whole-time medical officers in the public health

service were forwarded to the Ministry of Health and the Department of Health for Scotland in July, 1948, and were passed to the associations of local authorities. It was anticipated that discussions would begin in the autumn and be a part of the general negotiations on remuneration under Whitley machinery. Owing to the unwillingness of the associations of local authorities to participate in any negotiations under the machinery recommended by the Government, a prolonged delay resulted. In January the Council felt it had become necessary to inform the Ministry and the Department of Health for Scotland of the great dissatisfaction and disappointment of the profession regarding the position, and the Council accordingly decided

(a) That the Ministry be informed of the serious unrest and dissatisfaction among members of the public health service occasioned by the continued delay in the opening of negotiations on new scales and conditions of service.

(b) That the Ministry be informed that if negotiations through approved Whitley machinery have not begun by Feb. 28, 1949 advertisements from local authorities will not be accepted by the *British Medical Journal* unless the salaries offered are in conformity with the Association's own proposals for new scales.

(c) That negotiations be conducted on a national basis covering England, Wales, and Scotland.

The Council hoped that there would be no further postponement of the negotiations, but as by the end of February it became clear that co-operation from the local authority associations was unlikely the Council decided to take action in conformity with para (b) above. The Council desires to acknowledge the co-operation of the *Lancet*, the *Medical Officer, Public Health*, and *Medical World* in this matter.

Fees Payable by Local Authorities for Part-time Work

106. The scales of remuneration for sessional and part-time work undertaken by specialists and general practitioners for local authorities reported in the last Annual Report have been generally accepted. It was evident, however, that certain fees, such as remuneration of medical officers in charge of homes of varying types, police surgeons' fees, fees for medical officers to fire brigades, fees for certain certificates, etc., were not fully covered. The Council has given consideration to this problem, and its recommendations have been forwarded to the associations of local authorities. It is hoped that negotiations will begin at once.

Equal Pay—Consolidation of Salaries and Bonus

107. During the last year a large number of authorities have consolidated salaries and bonus and have accepted the Association's policy of equal remuneration for medical men and women. It was known, however, that in certain authorities there was still inequality and especially in those authorities where no consolidation had taken place and where unequal bonus continued to be paid. The Council decided to decline to publish in the *British Medical Journal* advertisements from local authorities in England, Wales, and Scotland who do not pay an equal bonus to men and women medical officers.

The result has been that in practically all areas equality of remuneration has now been gained.

Midwives Act—Fees for Attendances and Post-natal Examinations

108. The Council has made representations to the Ministry with a view to extending to three months the period during which claims under the Midwives Act may be submitted by practitioners.

Milk

109. The Council has made representations regarding the Milk (Special Designations) Bill, 1949. Representatives of the Public Health Committee gave evidence before the Parliamentary Medical Group and presented certain amendments which it is hoped will be incorporated in the Bill during the Committee stage.

Consideration has been given to the Milk and Dairies Regulations, 1949.

The Council has invited the National Veterinary Medical Association to participate in a joint committee with the following terms of reference :

That before the following A.R.M. resolution on milk is sent to the Ministries a copy be sent to the National Veterinary Association, and also a copy of the following A.R.M. resolution on foods of animal origin, together with a proposal that a joint committee of the B.M.A. and the National Veterinary Association, with equal representation, be appointed to consider and report, and formulate representations for transmission to Government departments, on the problem of providing safe milk of high quality for the community and the supervision of production and distribution of other foods of animal origin.

A.R.M. Resolutions referred to

146. "That this Meeting is dissatisfied with the present position in the production and distribution of milk and requests the Ministries of Food, Agriculture, and Health to consult with a Committee of the Association in order that safe milk of high quality be provided for the community and that the matter be treated with the utmost urgency."

148. "That this Meeting is not satisfied with the present supervision of production or distribution of foods of animal origin and asks the Council of the Association to approach the National Veterinary Association in order that a Joint Committee of the two bodies may investigate the matter and report to the proper authorities."

The joint committee is now at work and is discussing ways in which the policy of both Associations on "safe milk" can be implemented.

Children Act, 1948

110. Representations on the Children Bill which were made by Council, the main objects of which were to secure the adequate supervision by local authorities of all homes and institutions where deprived children are maintained, and the health and welfare of such children, have resulted in certain minor amendments in the Bill, which has now passed into law.

Civil Defence Act

111. The main objections raised by Council have been met by amendments to the Bill, which has now received the Royal Assent.

Report on Working Party on Midwives

112. This report, which is of wide interest to all branches of the profession, is now under consideration by the Council.

"BRITISH MEDICAL JOURNAL"

113. In the autumn of 1948 the circulation of the *British Medical Journal* reached for the first time the figure of 70,000. This was not due to a sudden increase, as the circulation has increased steadily each year since 1939. But the circulation has now reached a level which imposes a severe strain on the present mechanism of production and on the capacity of the *Journal* to include between its covers enough printed matter to keep the medical profession fully informed of the multifarious activities which concern it. The quantity of paper which the *Journal* is allowed to use is fixed, and out of this fixed quantity the increase in the circulation has to be met. The demand from Branches and Divisions, supported by the Council of the B.M.A., that more space should be given in the *Supplement* to medico-political information could not have come at a more inopportune time, when space had to shrink to allow for a circulation nearly double what it was in 1939. Nevertheless space was found at the expense of other sections of the *Journal*, and an attempt was also made to make the *Supplement* more attractive. The increase in the number of advertisements for posts and vacancies in the National Health Service has presented those responsible for the conduct of the *Journal* with still another problem, the solution to which can be found only in a larger allocation of paper from those who control the distribution of this commodity.

With the circulation of the *Journal* at its present size it is also becoming more and more difficult to produce it fast enough for distribution on time to members and subscribers. The Council has therefore decided that as soon as it can be arranged the *Journal* should, as before the war, be printed on

rotary machines, and not, as at present, on flat-bed machines, a method of printing that had through force of circumstances to be adopted in 1941. When this decision is implemented the rate of printing will be speeded up tenfold, and it will also be possible to have the *Supplement* stitched separately from the rest of the *Journal*.

Difficulties of production, shortage of paper, and mounting costs have been uppermost in the minds of those responsible for the *Journal* and the other twelve publications issued by the B.M.A. With one or two exceptions, there is no longer any delay in the publication of the ten quarterly journals. The cost of production, again owing to a steady increase of the prices of commodities and services, has, however, caused the Publishing Subcommittee some concern, and the Council has decided to increase the annual subscription of each quarterly journal to 30s., the present subscription having remained unchanged since 1926.

The two monthly journals *Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics and Gynaecology* continue to provide the medical profession with a wide but selective survey of the world's medical literature, and the periodicals received for this service exceed in number that of any other medical institution in Britain.

FINANCE

114. The year which ended on Dec. 31 last has been one of heavy expenditure, and for the first time for 20 years the income and expenditure account shows a deficit on the year's working. A large proportion of this expenditure is attributable to the action taken by the Association prior to the introduction of the National Health Service Act. This expenditure is non-recurring, but the cost of new and important services provided for our members will have to be faced in 1949 and the succeeding years, and unless the income from subscriptions is increased further deficits must be anticipated.

For the purpose of the balance-sheet the assets of the Association have been depreciated at the generous scale followed in past years.

The investments held as a backing for the Reserves stood at a market value of £174,446 on Dec. 31, 1948. This figure does not include the shares of Scholastic, Clerical, and Medical Association now in voluntary liquidation. These shares, which were purchased at a little over £10 each, are expected to realize a substantial profit when the liquidation is completed.

Cheques drawn in the last weeks of the year but not presented for payment amounted to over £14,000, but the bank account was not overdrawn, and consequently no liability for interest was earned. The accounts were subsequently met by the membership subscriptions collected in the first weeks of 1949.

Apart from the liability for income tax and the provision for Depreciation and Loss of Subscriptions, the published accounts for the year show that a sum exceeding £178,000 has been spent on maintaining and improving the services given by the Association to its members.

On Grants to Home and Overseas Branches, and direct expenditure on the periphery, including the establishment costs of Regional Offices, the Association spent £32,295 during the year. The cost of holding meetings of the Representative Body, the Council, and Committees amounted to £21,000. On General Expenses, to which are added the cost of the Empire Medical Advisory Bureau, the Medical Practices Advisory Bureau, and the Film Library, the Association spent £24,231. These services must necessarily lead to a substantial increase in the annual expenditure of the Association.

In addition to the cost of new books, the sum of £4,500 was spent on the Library. The balance of the year's expenditure included the cost of the Central Staff (£60,887), the Miscellaneous Printings, Stationery, and Postages (£16,296), which were much heavier than usual because of the circularization of the whole of the profession and the plebiscite undertaken prior to the introduction of the National Health Service Act, and the cost of maintaining the premises at Tavistock Square (£18,739).

As regards the income of the Association the membership at the close of 1948 reached a new record of 60,218, and the revenue from subscriptions increased to £145,000.

The interest realized on investments was greater during the year, but this was offset to some extent by a diminution in the rental income and in the dividend paid by the British Medical Bureau. In total, however, the income of the Association for the year was £171,847, as compared with £166,556 in the preceding year.

The Journal Account again shows a substantial increase in the revenue from Advertising and Publishing. Although the cost of production was considerably greater than the previous year the amount transferred to the Income and Expenditure Account was over £26,000.

The financial position of the Office Staff Superannuation Fund is sound, the market value of investments at Dec. 31, 1948, standing at nearly £60,000. The quinquennial valuation of the Fund will be carried out by the Actuary at the close of the present year.

Prizes have been awarded by the Funds for which the Council acts as Trustee. It is anticipated that the Investment Income of these Funds will be sufficient to meet the cost of the awards to be made during the coming year.

Subscriptions and donations to the Medical Charities have been maintained, and substantial allocations have been made to the Benevolent Funds.

It was decided to use the balance standing to the credit of the Central Contingency Fund to meet the major part of the cost of the administrative expenses of the Independent Fund.

Estimate of Receipts and Expenditure for the Year 1949

115. The following estimate of the probable income and expenditure for the current year is based on the accounts for 1948. Allowance has been made for probable reductions and for non-recurring items, and provision for new expenditure on activities which have already been approved by the Council.

Receipts	1948 Actual £	£	1949 Estimated £
Subscriptions ..	145,035	2,965 increase	148,000
Investments and Rents ..	26,713	2,713 decrease	24,000
Sundries ..	100		100
	<u>£171,848</u>		<u>£172,100</u>
Expenditure	1948 Actual £	£	1949 Estimated £
Central Meeting Expenses ..	20,839	3,139 decrease	17,700
General Expenses ..	24,232	6,768 increase	31,000
Remises ..	18,740	760 increase	19,500
Publication Grants, Regional Offices, etc.	32,296	2,296 decrease	30,000
Library Expenses ..	4,508	242 increase	4,750
Central Staff ..	60,887	2,813 increase	63,700
Printings, Stationery, and Postage ..	16,296	2,596 decrease	13,700
Work of Clerk and Architects' Fees ..	448	252 increase	700
Insurance ..	11,710	10 decrease	11,700
Provision for loss on Colonial Subscriptions	1,500		1,500
Provision for loss on Arrears of Subscriptions ..	3,000		3,000

Membership Subscription

116. The Annual Representative Meeting in July, 1947, passed the following resolution:

"That this meeting is of the opinion that the time has now arrived when an increase in present subscription rates should be considered."

The Council on consideration of the financial position of the Association as disclosed by the accounts for the year 1947 decided not to recommend an increase in the membership subscription, but undertook to consider the matter each year.

The question has again been reviewed by the Council in the light of the financial position of the Association as shown by the Annual Financial Statement for the past year. The Council is convinced that the time has come when it is necessary to increase the subscription of members of the Association. The Council proposes that the subscription of ordinary members at home should be increased from three to four guineas, with proportionate increases in the case of certain of the special groups of members. The Council anticipates that the additional revenue realized from subscriptions will meet the increase in the annual expenditure. If the A.R.M. approves this recommendation the Council will raise the non-members' subscription to the *British Medical Journal* from three to four guineas per annum.

The Council recommends—

Recommendation: That as from Jan. 1, 1950, the membership subscription rates be as follows:

Members Resident in Great Britain and Northern Ireland			
Ordinary subscription ..	£4	4	0 per annum
Not less than 40 years' membership ..	£2	2	0 per annum (no change)
Retired from practice with not less than 10 years' membership ..	£2	2	0 per annum (no change)
Whole-time non-professional member of teaching staff of a University or Medical School ..	£2	12	6 per annum
Engaged whole-time in investigation of scientific problems as distinguished from routine laboratory work ..	£2	12	6 per annum
Newly qualified practitioner elected within two years of registration ..	£2	2	0 per annum (for period of four years following registration)
Husband and wife residing together ..	£5	5	0 per annum jointly
Members resident outside Great Britain or Northern Ireland ..			
	£1	11	6 per annum (no change)
Service members, wherever resident ..	£2	12	6 per annum

The necessary amendment to By-law 16 consequent on the above recommendation is set out in Appendix IV to this report.

BUILDING

117. Considerable progress has been made during the past year with the repair and decoration of the Association's House. With the exception of the south wing, all the damage to the building by enemy action has been made good.

The Association has been successful in obtaining permission to complete the south wing, and in November last a licence was obtained for the carrying out of the first stage of the work, which includes the repair of the war damage and the completion of the structural work to roof level. It is estimated that this work will cost approximately £28,000.

A licence to cover the internal structural work will be applied for before the first stage is completed in order to ensure continuity of operations. The cost of this work is estimated at £34,500, making a total of £62,500 in all. Of this sum £16,000 will be recoverable from the War Damage Commission.

It is anticipated the south wing will be ready for occupation by September, 1950, providing no serious delays are made through prolonged frosts or shortage of materials.

A licence was also obtained for the reconditioning of the basement garage under the north wing, which is now in operation and provides free parking facilities for members visiting B.M.A. House, together with a valeting and light repair service at approved charges. Messrs. G. J. Shaffer, Ltd., who have been appointed to manage the garage, have installed at their

own expense equipment which includes petrol pumps and a greasing and oiling pit.

With the surrender by the Ministry of Works in December last of the accommodation held by them under requisition on the ground floor, Tavistock House South, there now remains only one suite of offices under requisition. This comprises practically the whole of the third floor, Tavistock House North, and every effort is being made to obtain its early return to the Association. When this accommodation is freed it has been decided it will, in the first instance, be made available to the Editor for reorganization of his departments.

The Council has approved a number of minor alterations and repairs to the Scottish House. The Scottish Committee, however, has been asked to prepare a comprehensive scheme of alterations which will improve the present office accommodation and amenities for the members using the Scottish House.

The Council has under consideration the lighting of the Garden Court Wing, and plans for the improvement of the common room and members' lounge facilities in B.M.A. House have been reviewed during the past year. For the convenience of members attending conferences, committees, and other meetings, a bar has been installed in the common room.

MEDICAL ETHICS

Ethical Problems Arising Out of the National Health Service

118. The Council has considered a number of ethical problems which have arisen since the introduction of the National Health Service. A point of some importance on the question of professional secrecy was raised in connexion with the many forms which have to be completed by members of the profession who are rendering service under the Act. The Council has reiterated its long-considered view that professional information, including that given on various forms and questionnaires, should not be divulged by practitioners without the consent of the patient.

The opinion of the Council has been sought about the steps which might be taken when local rumour or the report of an executive council has caused an inaccurate statement regarding a doctor's practice or retirement to be published in the local press. The Council has advised against any publication of a correction and has recommended the circularization, under cover, of the facts to the patients of the practitioner.

The Council has expressed the opinion that while the position in law appears to be that a practitioner suitably qualified may enter his name on two or more lists under the National Health Service—for example, as a general practitioner, an optician, or a pharmacist—this possibility is to be deplored on the grounds that it is beneath the dignity of the profession so to act and may promote unethical practices; also, that it is undesirable for a medical practitioner to have his consulting-rooms in premises occupied by a chemist or optician or for a chemist or optician to have his shop in premises occupied by a medical practitioner.

The Council has reviewed the arrangements made by certain industrial firms for the ophthalmic examination of their employees and has expressed disapproval of any arrangements which do not safeguard the general practitioner's recognized custom of referring his patients to the specialist of his own choice. The Council regards as particularly undesirable arrangements which tend to operate to the exclusion of other ophthalmic practitioners in the area.

Entries in Telephone Directories

119. The Council has examined the general question of entries in telephone directories which relate to medical practitioners and has raised no objection to the inclusion of medical practitioners' names under the heading of "Physicians and Surgeons" in the Classified (Trades and Professions) Directory. The Council has, however, expressed the opinion that it is undesirable for the specialties of medical practitioners to be published in telephone directories.

Rules of Procedure Governing Ethical Matters: Rules for Medical Inspectors

120. The Rules of Divisions and Branches governing procedure in ethical matters were adopted in 1919 and a revision of these Rules has become necessary so as to bring them up to

date in the light of existing conditions. The Ethical Rules for medical inspectors also need revision. The Council hopes to deal further with these matters in its Supplementary Report.

The Medical Practitioners' Handbook

121. Before the war the Association published a *Medical Practitioners' Handbook*. This was of particular value to recently qualified practitioners, as it contained much useful information on the practical aspects of medical work. The Council has decided to prepare a new edition of this *Handbook*, but pending its publication it is proposed to prepare a short pamphlet on medical ethics for issue to newly qualified practitioners.

Dr. N. E. Waterfield

122. The Council has placed on record its appreciation of the valuable service rendered to the Association by Dr. N. E. Waterfield as chairman of the Central Ethical Committee for the period 1936-48.

CORONERS' ACTS

123. The Council has given further consideration to certain recommendations contained in the Report submitted to the A.R.M. in 1948 on the working of the Coroners' Acts.

Mortuary Accommodation and Pathological Facilities

Paragraph 118 of the Annual Report of Council, 1947-8, relating to mortuary accommodation and pathological facilities, contained the following clause:

(iv) That mortuaries be established at central points in each Coroner's jurisdiction, under the control of the Local Health Authority, equipped with refrigeration and a separate viewing-room for relatives, the post-mortem rooms being furnished with good lighting, heating, and an ample supply of running water, and with facilities for histological examinations and the proper collection of specimens for toxicological examinations; that the assistance of trained mortuary attendants be made available; that adequate transport facilities for bringing cadavers to the central post-mortem establishment from outlying mortuaries be provided.

The Council is of the opinion that this should be amended to read as follows:

(iv) That mortuaries be made available at central points in each Coroner's jurisdiction, equipped with refrigeration and a separate viewing-room for relatives, the post-mortem rooms being furnished with good lighting, heating, and an ample supply of running water, and with facilities for the collection of specimens for histological and toxicological examinations; that the assistance of trained mortuary attendants be made available; that adequate transport facilities for bringing cadavers to the central post-mortem establishment from outlying mortuaries be provided; and that exception be not taken to the use of the local hospital mortuaries for the conduct of necropsies, provided the pathologist nominated by the coroner is given facilities to use these premises for that purpose.

Mobile Laboratories

The Council has reconsidered the following recommendation contained in paragraph 119 of the Annual Report of Council, 1947-8, and referred back by the Representative body (Minute 182):

That as an interim measure urgent consideration be given to practical steps for mobilizing pathologists and enabling them to travel to the various outlying mortuaries with fully equipped motorized laboratories.

The Council has decided to substitute the following for the recommendation quoted above:

That as an interim measure urgent consideration be given to the adoption of practical steps for mobilizing pathologists and enabling them to travel to the various outlying mortuaries, but that whenever practicable the cadaver be brought to the pathologist for examination.

Implementation of Report on Coroners' Acts

The Council proposes that its report on the medical aspects of the Coroners' Acts, amended in accordance with the decisions of the Representative Body, shall be officially

submitted to the Home Office, the Coroners' Society, and the Association of Clinical Pathologists with a view to implementation.

ORGANIZATION

Election of Central Council of the Association

124. During the session the Council has examined its present constitution and has had regard to the desire expressed from several quarters that a greater proportion of its members should be directly elected by members in the Divisions and Branches. A study of the problem showed that many of the existing electoral areas are too extensive to allow members of Council to have effective contact with their constituents, and that what is needed is the division of the country into more compact electoral areas for the purposes of election to the Association's Central Executive. If this principle be accepted it must inevitably lead to an increase in the number of members directly elected to Council and, if the size of the Council is not to be greatly increased, to a reduction of the number of members appointed or elected by other means. The Council has considered the following suggestions:

(a) That the arrangements under which twelve members of Council are elected by grouped representatives, and eight members are elected by the Representative Body as a whole, should be discontinued; and

(b) That there should be a reduction in the number of *ex-officio* members of the Council.

Elected Members

As regards the first proposal, the Council, after careful consideration, has come to the conclusion that there are advantages to the Association in electing to the Council an adequate number of members on their experience and knowledge in the medico-political field and not as representatives of any given area. It also feels that the Representative Body should have an opportunity of electing to the Council "elder statesmen" and any member of the Representative Body who has gained the confidence of the meeting.

The Council proposes, therefore, that the number of members to be directly elected by members in the Branches and Divisions of the Association in Great Britain and Northern Ireland should be increased from 22 to 37; that the arrangement under which 12 members of Council are elected by Representatives of constituencies of Branches and Divisions in Great Britain and Northern Ireland should be discontinued; that the Representatives of constituencies in Scotland should elect 2 members of Council; that the Representatives of constituencies in Wales should elect one member of Council; and that 10 members should be elected by the Representative Body as a whole. The effect of this plan would be that Scotland, Wales, and Northern Ireland would respectively elect 6, 3, and 2 members to the Council (as at present) but that the number of members elected by England would be increased from 23 to 29.

The Ex-Officio Members of the Council

There are at present 10 members of the Council, *ex officio*. The Representative Body agreed in 1948 that the chairman of the Central Consultants and Specialists Committee should be a member, *ex officio*, of Council, and the Council proposes that this plan should apply also to the chairman of the General Medical Services Committee.

The Council is of the opinion that the number of *ex-officio* members of the Council should be reduced. In its view it would not seem to be important to retain amongst the list of *ex-officio* members the immediate past chairman of the Representative Body, the deputy chairman of the Representative Body, and the past treasurer, as it will still be open to these officers to secure election from among the members of Council elected by the Representative Body as a whole.

Representation of Branches of the Association Overseas

The Branches in India and Pakistan have, to a material extent, ceased to function, with the result that the number of members elected by Branches overseas will be reduced from 8 to 7.

Effect of the Foregoing Proposals on the Future Constitution of the Council

If the foregoing proposals are approved their effect on the constitution of the Council would be as follows:

Existing Constitution	Proposed future Constitution
<i>Ex officio:</i>	<i>Ex officio:</i>
10 President	9 President
President-Elect	President-Elect
Immediate Past President	Immediate Past President
Chairman of Representative Body	Chairman of Representative Body
Immediate Past Chairman of R.B.	Chairman of Council
Deputy Chairman of R.B.	Immediate Past Chairman of Council
Chairman of Council	Treasurer
Immediate Past Chairman of Council	Chairmen, Central C. & S. Committee
Treasurer	Chairman, G.M.S. Committee
Past Treasurer	
22 directly elected by Members in Great Britain and Northern Ireland	37 directly elected by Members in Great Britain and Northern Ireland
12 elected by Grouped Representatives	2 elected by Representatives of constituencies in Scotland
8 elected by Representative Body as a whole	1 elected by Representatives of constituencies in Wales
8 elected by Branches outside Great Britain and Northern Ireland	10 elected by Representative Body as a whole
2 elected by Public Health Service members	7 elected by Branches outside Great Britain and Northern Ireland
3 Service representatives	2 elected by Public Health Service members
1 elected by women members	3 Service representatives
	1 elected by women members
66	72

"The Six-year Rule"

The Council has considered a proposal that one-third of the members of Council should retire annually. It does not favour this plan. The present position is that a member of Council who has served for six successive years as the representative of a group or class of members is ineligible for one year to represent that group or class. The Council is of the opinion that this rule, the "six-year rule," should be abolished provided there is an annual election, except in the case of members of Council elected by overseas Branches, who will be elected (as at present) for a three-year period.

Plan for Grouping for Direct Election of 37 Members of Council

The Council submits the following provisional plan for the grouping for direct election of 37 members of Council. The Council is giving further consideration to this plan and may suggest minor modifications before the Annual Representative Meeting.

Group	Area in terms of B.M.A. Branches or Divisions	Proposed No. of seats	Membership
(i) England and Wales			
A	Divisions of North of England	2	1,764
	Branch in North Eastern Region		
	Cumberland		
	Westmorland (part)		
B	East Yorkshire Branch	2	2,767
	Yorkshire Branch		
C	Divisions of Lancashire and Cheshire Branch in Liverpool	1	1,432
	Hospital Region (St. Helens, Liverpool, Southport, Birkenhead, Chester, Warrington, Wallasey)		
D	Divisions of Lancashire and Cheshire Branch covered by Manchester Hospital Region	3	2,873
	Isle of Man		
	Western part of Westmorland (Alternatively Lancashire and Cheshire and Isle of Man should be 1 Group electing 4 Members.)		

Area in terms of B M A Group Branches or Divisions	Proposed No of seats	Member- ship
E Lincolnshire Branch	2	1,599
Derbyshire Branch		
Nottinghamshire Branch		
Leicestershire Branch		
F Birmingham Branch	2	2,473
Staffordshire Branch		
Worcester and Hereford Branch		
G Berks, Bucks, and Oxford Branch	1	1,309
Northamptonshire Branch		
H Cambs and Hunts Branch	1	995
Norfolk Branch		
Suffolk Branch		
I Metropolitan Counties Branch	2	1,915
(Divisions in Middlesex)		
J Metropolitan Counties Branch	4	5,273
(Divisions in London, Stratford, and S W Essex)		
K Hertfordshire Branch	1	1,395
Essex Branch		
Bedfordshire Branch		
L Surrey Branch	2	1,838
M Kent Branch	1	1,271
N Sussex Branch	1	1,062
O South Western Branch	1	999
Dorset and West Hants Branch		
P Bath, Bristol and Somerset Branch	2	1,618
Gloucestershire Branch		
Wiltshire Branch		
Q South Western Branch	1	999
R North Wales Branch	1	699
Shropshire and Mid Wales Branch		
S South Wales and Monmouthshire Branch	1	1,293
(ii) Scotland		
T Aberdeen Branch	1	1,333
Dundee Branch		
Northern Counties of Scotland Branch		
Perth Branch		
U Edinburgh and South East of Scot- land Branch	1	1,544
Fife Branch		
V Glasgow and West of Scotland Branch (Glasgow Division)	1	1,157
W Border Counties Branch (Dumfries and Galloway)	1	1,569
Glasgow and West of Scotland Branch (6 County Divisions)		
Argyllshire		
Ayrshire		
Dumbartonshire		
Lanarkshire		
Renfrewshire and Buteshire		
West Wigtownshire		
Stirling Branch		
(iii) Northern Ireland		
X Northern Ireland Branch	2	1,212

Recommendation: That the Representative Body approve the principle that the number of members of Council directly elected by members in the Branches and Divisions of the Association in Great Britain and Northern Ireland should be increased

Recommendation: That the number of members to be directly elected by members in the Branches and Divisions of the Association in Great Britain and Northern Ireland be increased from 22 to 37

Recommendation:

(i) That two members of Council be elected by Representatives of constituencies in Scotland;

(ii) that one member of Council be elected by Representatives of constituencies in Wales, including Monmouthshire, and

(iii) that 10 members of Council be elected by the Representative Body as a whole

Recommendation: That the following cease to be members, *ex officio*, of the Council. (a) Immediate Past Chairman of Representative Body; (b) Deputy Chairman of Representative Body; and (c) Immediate Past Treasurer.

Recommendation: That the number of members elected by Branches of the Association not in Great Britain or Northern Ireland should be reduced from 8 to 7 consequent on the dissolution of the majority of the Branches of the Association in India and Pakistan

Recommendation: That the following proviso to By-law 61 (1) be abolished:

that a person who has served as the representative on the Council of one and the same Branch or Group of Branches or group or class of Members for six years successively shall for one year be incapable of being elected as such representative

Recommendation: That the Chairmen of the General Medical Services and Central Consultants and Specialists Committees be members *ex officio*, of the Council

The appropriate amendments to the Articles and By-laws are embodied in Appendix IV

Association Membership

125 The Council submits the following report upon the membership of the Association for 1948

New members		4,112
Resignations withdrawn		58
Reinstated		2
S.A.M.A. resumed membership		30
		4,602
Removed in arrears	2,162	
Less paid arrears	1,117	1,045
Resignations, etc		533
Deaths		524
Erased from Register		1
		2,103
		Increase 2,499
Membership, Dec 31, 1947		57,719
Membership, Dec 31, 1948		60,218

The total number of practitioners resident in the United Kingdom, including Services, is estimated to be 58,303, and of these 44,340 were members of the Association at the end of 1948. This represents an Association membership in the United Kingdom amounting to 76% of the total profession. If retired practitioners be excluded the percentage of Association membership is 78.7% of the working profession in the United Kingdom

The membership on March 23, 1949, was 60,341

Relationship of the Association to the Profession in India and Pakistan

126 The Council has under consideration proposals for affiliation with the Indian Medical Association and hopes to enter into similar arrangements with the Pakistan Medical Association as soon as the opportunity occurs

Election of Chairmen of Standing Committees

127. By-law 79 provides that, with certain exceptions, each Standing Committee shall appoint from its own number a member of Council as chairman. In the case of the excepted committees each committee has power to appoint any member of the committee as chairman, but where the member appointed as chairman is not a member of Council the committee is required to appoint from its own number a member of Council as deputy chairman

The Council is of the opinion that every Standing Committee should be entitled to appoint any member of the committee as its chairman, and it proposes that By-law 79 should be amended to meet this position (see para 137 below)

Business at Representative Meetings

128. The Council has under consideration the general question of the method of dealing with the business at Representative Meetings

The Council hopes to submit a detailed report on the subject in its Supplementary Report

Regional Development

129. An important new development during the year has been the establishment of regional offices of the Association in various parts of the country. The function of the regional office

is to provide clerical facilities for the honorary secretaries of Branches and Divisions and of the Regional Consultants and Specialists Committees. The regional office will undertake the preparation and issue to members of notices of meetings and other information which honorary secretaries may wish to circulate. Secretaries of local units are strongly urged to make use of the facilities of the regional offices in order to relieve themselves of clerical work.

Regional offices are now functioning in London, Manchester, Cambridge, Leeds, Oxford, and Sheffield. Another office will shortly be opened at Liverpool.

The arrangement whereby each assistant secretary has a special interest in the Branches and Divisions in areas, usually comprising about three hospital regions, has continued during the year. There is ample evidence that the advice given to officers of Divisions and the visits paid to meetings are proving helpful and are appreciated. The increasing number of letters addressed to assistant secretaries by individual members to whom they have been introduced on their visits to the periphery is an indication of the value of the personal contacts thus afforded.

While assistant secretaries will encourage the development of the regional offices and the expansion of their activities, it is clear that they can best serve the members in their areas if they themselves are intimately concerned with the work at Headquarters and are responsible for central committees.

Constitution of Ceylon Branch

130. With the change in the constitutional status of Ceylon, a desire has been expressed by the Ceylon Branch that it should become an incorporated body within the terms of Article 13 and By-law 21. The Council has submitted proposals to the Branch to give effect to such an arrangement.

Formation of New Divisions: Areas of Branches

131. The Council has formed the following new Divisions in response to the wishes of the members residing in the areas concerned: Caithness, Sutherland, Sutton Coldfield, Wembley, West Derbyshire, and West Wigtownshire.

The Council has also had under consideration the general question of the areas of the Branches of the Association. Whilst the Council is convinced that it would not be desirable to attempt to relate the Branches of the Association as a whole to areas of Regional Hospital Boards, it seems probable that a modification of the areas of a number of Branches may become necessary. This is essentially a problem which concerns the members in the Branches affected, and the Council prepared to take such steps as are considered desirable by them to improve the local organization of the Association.

Amendment of Association's Constitution Consequent on the Companies' Act, 1948

132. The passing of the Companies' Act, 1948, will necessitate certain modifications in the constitution of the Association. These modifications are largely of a technical nature, and the necessary amendments, drafted by counsel, are embodied in Appendix IV of this Report.

Deputy Chairman of Representative Body

133. By-law 70 provides that whilst holding office the chairman of Representative Body shall not act personally as the representative of any constituency, and to meet this situation the constituency which the chairman represents at the time of his election is represented by a deputy representative. The Council is of opinion that a similar procedure should apply in the case of the deputy chairman of the Representative Body. The necessary amendment to the By-law is set out in Appendix IV of this Report.

Representation of Divisions in Representative Body

134. The Council has decided that the grouping of Divisions for the election of Representatives to the Representative Body, 1949-50, shall be on the same lines as for 1948-9, except that the newly formed Sutton Coldfield, Wembley, and West Derbyshire Divisions have been made independent constituencies.

The Honorary Secretary

135. The period covered by this report has been one of considerable activity for the Association, and the Council, on behalf of the general body of members, desires to express the great debt which the Association owes to honorary secretaries of the Divisions and Branches without whose loyal co-operation the Association could not function as an efficient organization.

Conference of Honorary Secretaries

136. A Conference of Honorary Secretaries of Divisions and Branches will be held on Tuesday, May 10, at 11.30 a.m.

Amendments to Articles and By-laws

137. The proposals made by the Council in the foregoing paragraphs of this Report will involve amendments to the Articles and By-laws. The Council recommends:

Recommendation: That the Annual Representative Meeting approve and adopt the amended Articles and By-laws set out in Appendix IV of this Report, and that the Council be instructed to submit the amended Articles to an Extraordinary General Meeting of the Association for adoption as Articles of Association.

NUTRITION

138. The special committee appointed by the Council to consider the problems of nutrition in this country has examined reports received from four subcommittees which were set up to investigate different aspects of the subject.

The report of the committee, based on the findings of the subcommittees, is now being prepared.

SCIENCE

Association Prizes

Nathaniel Bishop Harman Prize

139. The prize of approximately £100 initiated by the late Mr. N. Bishop Harman in 1939 for research in consulting practice was awarded in 1948 and, although these awards should as a rule be granted biennially, the Council considered that the amount standing to the credit of the Fund justified an award being made in 1949.

Katherine Bishop Harman Prize

An essay competition for the Katherine Bishop Harman Prize for the encouragement of study and research into the disorders incident to maternity was opened in 1948. Prizes of certificates and cheques for £75 each have been awarded to Dr. Roberta Irene Hutchinson (Birmingham) for her essay "On the Significance of the Less Well-known Strains of Haemolytic Streptococci (Lancefield Groups B, C, D, and G) in the Pregnant and Puerperal Woman and her Attendants," and to Dr. Charles Spencer Swan (Mitcham, South Australia) for a paper on "Rubella in Pregnancy as an Aetiological Factor in Congenital Malformation, Stillbirth, Miscarriage, and Abortion."

Sir Charles Hastings Clinical Prize

The annual Sir Charles Hastings Clinical Prize, consisting of a certificate and a cheque for 50 guineas for the promotion of systematic observation, research, and record in general practice, has been awarded to Dr. Charles Ernest Lewis Burman (Pietermaritzburg, Natal) for an essay entitled "A Survey of Records of Surgery in General Practice."

Middlemore Prize

The Middlemore Prize is given triennially from a fund endowed by the late Mr. Richard Middlemore, F.R.C.S., of Birmingham, for the best essay or work on any subject which the Council may select in any department of ophthalmic medicine or surgery. The Council in 1948 opened an essay competition for the Prize on the subject "The Value of Orthoptics in the Treatment of Squint," and has awarded to Dr. Alastair Alexander Douglas (Birmingham) a certificate and a cheque for £50 for his entry.

Prizes for Nurses

140. The Council has decided that the subjects for essays to be submitted in connexion with the Association's prizes for nurses in 1949 shall be as follows, prizes of 20 guineas and 10 guineas respectively being awarded for the best and second best entries in each category: (i) Student nurses—"What discipline do you think necessary in the training of nurses?" ; (ii) State-registered nurses working in hospital—"What part of nursing duties can be delegated to others with safety?" ; (iii) State-registered nurses not working in hospital—"The care of old people in their own homes."

Prizes for Medical Students

141. The subject chosen by the Council for entries submitted for the national and regional prizes of the Association's essay competition for medical students to be awarded in 1949 is "The Value of Observation in the Training of the Medical Student."

Research Scholarships

142. The following scholarships have been awarded, tenable for the twelve months beginning Oct. 1, 1948:

Walter Dixon Memorial Scholarship (£200): R. P. Jepson, M.B., Ch.B., F.R.C.S., of Manchester. An investigation into the mechanism and treatment of intermittent claudication in *arteriosclerosis and Raynaud's disease*.

Ernest Hart Memorial Scholarship (£200): J. Brodie, M.D., D.P.H., of Dundee. An attempt further to elucidate the mechanisms involved in the differential inhibition of coliform bacilli and rough variants of intestinal pathogens.

Ordinary Research Scholarships (£150 each): E. J. Field, M.D., M.S., of Bristol. Study of the structure and innervation of the conducting system in the heart of the rabbit, sheep, monkey, and man, and the histological and electrocardiographic effects of cardiac hypertrophy resulting from experimental aortic stenosis.

C. W. C. Gough, M.B., D.M.R.E., Major, R.A.M.C., in B.A.O.R. Increase of the brilliancy of the x-ray screen by television principles.

E. S. Jones, M.B., Ch.B., M.R.C.P., of Liverpool. (a) Determination of the importance or otherwise of the hyaluronidases in rheumatic states affecting man; (b) application to human problems of experimental work already carried out by others on animals; (c) study of the inhibitory effects of salicylates and para-aminobenzoic acid on the spreading factors.

Frances B. Robinson, M.B., Ch.B., of Bristol. An investigation of the effects of different anaesthetics on the adrenal cortex.

The first award of the Insole Scholarship (£250) for research into the causes and cure of venereal disease was made in 1948, but the scholar subsequently withdrew his acceptance. The Council has invited applications for the award of this scholarship, which is normally given biennially, in 1949.

Education of the Public in Health Matters

143. The Council has considered the part the Association could take in the promotion of health education amongst the general public. It is of the opinion that much can be done at Divisional level to encourage an interest in this subject and that Divisions should hold meetings to discuss the problems involved with medical officers of health. The Secretary of the Central Council for Health Education has stated that he or other representatives of the Central Council would be willing to attend Divisional meetings to assist in such discussions.

The role of health centres in the health education of the public will be discussed in the Council's report on health centres. It may be mentioned here, however, that the opinion of the Council is that the only kind of health education appropriate to a health centre is that private education which is inseparable from personal medical attention. It considers that any attempt to use health centres for public health propaganda should be actively discouraged in the experimental period.

Systematic health education cannot, in the opinion of the Council, be carried out in hospital. It has been suggested that the organization of discussions with groups of in-patients might be useful, but the Council considers that this is better done by the doctor, ward sister, or almoner in conversation with the individual patient.

So far as health education in schools is concerned the Council considers that members of the profession should interest themselves in the education of children in health

matters, both directly and indirectly through teachers. It suggests that discussions between teachers and others concerned might be arranged under the aegis of local authorities or by the particular school authorities, and that teachers so instructed should deal with the matter in the course of their ordinary work rather than as a special subject. It is strongly of the opinion that if health education in schools is to be effective it is essential that it should be given against a background of similar education amongst members of the general public in order to ensure that a child will not encounter in its home opposition to health concepts learned in school.

Foreign Corresponding Members

144. It is within the power of the Council to elect as Foreign Corresponding Members of the Association any persons who (a) are not eligible for ordinary membership of the Association, (b) are not British subjects or ordinarily resident in Great Britain or the Commonwealth, and (c) are in the Council's opinion distinguished by eminent services rendered to medical science or to the medical profession. On the occasion of the Centenary of the Association in 1932 twelve such members were elected. Other appointments were made from time to time until 1939, but since that date no other elections have been made. The Council has accordingly invited the following to accept Foreign Corresponding Membership of the Association:

Dr. Georg Domagk (Germany), Pharmacologist and Bacteriologist, I.G. Farben Industrie. Nobel Prizewinner.

Dr. Bernardo Alberto Houssay, M.D. (Argentina), late Professor of Physiology, University of Buenos Aires. Nobel Prizewinner, 1947. Honorary Member, Physiological Society. Foreign Member, Royal Society.

Professor Elliot Proctor Joslin, A.M., M.D., Sc.D. (U.S.A.). Emeritus Professor of Medicine, Harvard Medical School.

Professor Einar Key, M.D. (Sweden). Emeritus Professor of Surgery, Caroline Medico-Surgical Institute, Stockholm. Honorary F.R.C.S.

Professor René Leriche, M.D. (France), Professor, Collège de France. Honorary F.R.C.S.

Professor Einar Meulengracht, M.D. (Denmark), Professor of Clinical Medicine, University of Copenhagen. Honorary LL.D. (Aberdeen). Corresponding Member, Royal Society of Medicine.

Professor Adolf Meyer, M.D., LL.D., Sc.D. (U.S.A.), Professor of Psychiatry, Phipps Institute, Baltimore.

Professor George Richards Minot, M.D., Sc.D., F.A.C.P. (U.S.A.), Professor of Medicine, Harvard Medical School. Nobel Prizewinner, 1934. Moxon Medal, Royal College of Physicians, 1933. Distinguished Award, American Medical Association, 1945. Honorary F.R.C.P. (London and Edinburgh). Honorary F.C.P. (Philadelphia).

Dr. Emil Novak, M.D. (U.S.A.), Associate in Clinical Gynaecology, College of Physicians and Surgeons, Baltimore.

Professor Alfred Newton Richards, A.M., Ph.D., Sc.D., M.D. (U.S.A.). President, National Academy of Science, Washington. Recently Professor of Pharmacology and Vice-President, University of Pennsylvania. Honorary LL.D. (Edinburgh). Honorary Fellow and Foreign Member Royal Society. Croonian Lecturer, Royal Society, 1938.

Dr. Francis Peyton Rous, M.D., D.Sc. (U.S.A.). Pathologist, Rockefeller Institute. Honorary Fellow, Royal Society of Medicine. Foreign Member, Royal Society. Walker Prize, Royal College of Surgeons, 1941.

Dr. Arvid Johan Wallgren, M.D. (Sweden), Chief Paediatrician, Children's Hospital, Gothenburg. Corresponding Member, British and French Paediatric Societies.

Professor Allen Oldfather Whipple, M.D., Sc.D. (U.S.A.). Professor of Surgery, College of Physicians and Surgeons, Columbia University. Honorary F.R.C.S.

B.M.A. Lectures

145. The Council thanks the following, who have given B.M.A. Lectures during the period March 1, 1948, to Feb. 28, 1949: Dr. Evan Bedford, Dr. D. J. Guthrie, Dr. J. R. Rees, Professor Lambert Rogers, Professor Robert Platt, Sir Heneage Ogilvie, Professor L. J. Wits, Dr. R. M. B. MacKenna, Sir Alexander Fleming, Professor Wilfrid Gaisford, Professor

F. J. Browne, Dr. E. A. Carmichael, Miss Meave Kenny, Dr. Margaret Moore White, Sir Hugh Cairns, Mr. A. Dickson Wright, Dr. William Evans, Professor H. L. Sheehan, Professor A. M. Boyd, Professor A. A. Moncrieff, Dr. Horace Joules, Professor E. B. Astwood, Mr. R. C. Brock, Dr. Harold Dodd, Mr. A. J. Wrigley, Lord Horder, Mr. Alan Brews, Mr. W. J. H. M. Beattie, Professor Mathew Steward, Mr. John Barron, Professor Ian Aird, Dr. Henry Yellowlees, Professor R. McWhirter, Dr. Wilfred Sheldon, Dr. W. Lister, Mr. A. M. A. Moore, Dr. Lee Lander, Mr. E. W. Riches, Professor J. Glaister, and Dr. K. Hermann.

Divisions and Branches are reminded that they may have one "B.M.A. Lecture" during the course of a year. The lecturers are nominated by the Division or Branch and an honorarium of ten guineas with first-class railway fare and incidental expenses are paid to the lecturer by the Council from central funds.

Library

146. The Library of the Association was moved to more commodious quarters in November, 1947, and the statistics for the first complete year in the Garden Court Wing show increases in all departments of Library activities. A considerable number of new journals have been added, and the collection of current medical periodicals is now one of the finest in the country. Members are reminded that any journal, excluding the current issue, can be borrowed. The Library endeavours to cater for the practical everyday needs of the practising doctor. Important new books are added as published, and reference copies of standard textbooks are available. The Recordak microfilm reader is installed, and may be used by any member. A microfilm section is in process of development.

The new reading rooms are light and quiet, and many members have passed favourable comments on them. All members are requested to visit the Library when in B.M.A. House.

PUBLIC RELATIONS

National Health Service

147. On the medico-political side the past year has been one of exceptional difficulty in respect of the Association's public relations. The introduction of the National Health Service was accompanied by many misconceptions among the public. The Public Relations Department has striven, through the Press and by other means, to clear up these misconceptions. Thus charges made in Parliament against the conduct of some practitioners were countered by a statement which was issued in August, 1948, to every newspaper and given wide publicity. The Association's views on the inadequacy of the capitation fee, the hardships of the rural practitioner, the refusal of N.H.S. drugs to private patients, and many similar subjects have been continuously brought to the notice of the Press.

Public relations activity during the year has also tried to lighten the increased burden of work falling on the profession as a result of the Service. In newspaper articles, statements, letters to the Press, guidance for such bodies as the B.B.C. and the news-film companies, the need for restraint in the calls made on the doctor's time by the public has been consistently emphasized. A popular illustrated leaflet, "The New Health Service and You," was prepared for public distribution in order to emphasize this point and also to stress, in the words of the S.R.M. Resolution of May 28, 1948, that "for reasons outside the control of the profession the inception of the new Service cannot be followed for some time to come by all the improvements promised by the Government in the medical services of the country." Distribution of this leaflet was undertaken from B.M.A. House to every practitioner who asked for a supply. Over half a million copies of the leaflet were sent out.

A wide demand was also experienced for another leaflet, "The Private Patient and the National Health Service," which aimed at clearing up a double misconception: (a) that if a member of the public decided to remain as a private patient with his general practitioner he would not be entitled to the benefits of the Health Service, and (b) that the bulk of the public's weekly contribution was being spent on the Health Service.

A poster, "Help Your Doctor to Help You," appealing to the public not to burden the doctor with requests for needless visits and to make any necessary requests early in the day,

was also prepared and widely distributed. Many copies have been displayed in Local Executive Council offices.

Reference Book of Medical Scholarships

148. No full reference book of medical scholarships at present exists. Material for such a reference book is now being compiled at B.M.A. House. It is planned to give details of all scholarships and grants for medical training (entrance, in training, and postgraduate) awarded throughout the country. It is felt that such a reference book will be of great value to parents, careers' masters in schools, advice bureaux, and similar persons and organizations concerned with guiding those seeking entry to the profession. Medical schools, universities, and charitable organizations throughout the country have been approached and have promised their co-operation.

Information Service

149. The Information Service at B.M.A. House has made steady progress during the year, and the number of daily inquiries has greatly increased. There is every sign that this new facility for supplying information and guidance on health and medico-scientific matters, as well as on medico-political questions, is greatly appreciated by the Press and other organizations which are making use of the service.

An interesting feature of the year has been the large number of journalists and social workers from abroad, especially from the U.S.A., who have called to obtain information and opinions on the working of the National Health Service.

PSYCHIATRY AND THE LAW

150. The Council has received from the Joint Committee of the Association and the Magistrates' Association a memorandum entitled "The Criminal Law and Sexual Offenders." The memorandum was published in the *Supplement* of March 12, 1949. It has also been printed in pamphlet form. The memorandum deals with cases that appear before Magistrates Courts, and emphasizes the need for adequate remand to enable psychiatric examination to be undertaken and appropriate treatment to be given.

Consideration is now being given to the preparation of a memorandum on "The Delinquent Adolescent Boy." It is hoped to complete this memorandum during the present year.

ARMED FORCES

Rates of Pay of Service Medical Officers

151. In accordance with the undertaking given to the Representative Body in 1948, the Council has reviewed the rates of pay of medical officers in the Armed Forces in the light of the recommendations of the two Spens Committees on the remuneration of civilian medical practitioners. It considers that a difference between the pay of general duty officers and specialist officers, between the ages of 35 and 54, of the same order as the difference between the recommendations of the General Practitioner Spens Committee and the Specialist Spens Committee would be inappropriate in the Armed Forces. It is also of the opinion that the pay of medical officers in the Armed Forces should include an element of compensation for the disadvantages of their career, such as frequent changes of domicile and long periods of service overseas. The Council considers that pay in the Armed Forces at the earlier ages—i.e., 25 to 34—should be relatively generous in order to attract recruits.

The difference between the general duty and specialist rates recommended by the Council is 6s. a day (£110 p.a. for graded specialists and 9s. a day (£165 p.a.) for full specialists. The Council makes no recommendations for changes in the allowances. The allowances of a married officer have been included in the Armed Forces remuneration for the purposes of comparison with the Spens Reports.

Representations have accordingly been made to the Ministry of Defence that, in order to bring the remuneration of Service medical officers into relation with the levels of professional income in the National Health Service, the rates of pay of medical officers in the Armed Forces should be revised to ensure that married general duty and specialist medical officers receive total annual emoluments upon the scale set out below.

Rank	Total Annual Emoluments	
	General Duty Officer £	Specialist Officer £
Acting Surg. Lieut. R.N., Lieut. F/O	855	
Surg. Lieut. R.N., Capt. Fl Lieut.	965	
Do. After 3 years' commissioned service	1,074	
Do. " 7 " " "	1,184	1,294
Surg. Lieut. Com., Major, Sq. Ldr.	1,293	1,403
Do. After 10 years' commissioned service	1,458	1,623
Do. " 12 " " "	1,512	1,677
Do. " 14 " " "	1,567	1,732
Surg. Com., Lieut.-Col., Wing Com.	1,622	1,787
Do. After 2 years' service as such	1,831	1,996
Do. " 4 " " "	1,886	2,051
Do. " 6 " " "	1,941	2,106
Do. " 8 " " "	1,995	2,160
Surg. Capt., Col., Group-Capt.	2,050	2,215
Do. After 2 years' service as such	2,251	
Do. " 4 " " "	2,306	
Do. " 6 " " "	2,360	
Surg. Capt. (after 5 years' service as such), Brig. Air	2,415	
Cdre.	2,571	2,571
Surg. Rear-Admiral, Ma.-Gen. Air Vice Marshal	2,872	2,872
Surg. Vice-Admiral, Lieut.-Gen., Air Marshal	2,274	

A memorandum on this subject submitted by the Council to the Ministry of Defence is included at Appendix V.

The Council is also engaged, with actuarial assistance in a comparison of the pensions payable to officers of the Armed Forces with the benefits of the National Health Service Superannuation Scheme.

SCOTLAND

Chairman and Deputy Chairman of Scottish Committee

152. Dr. George MacFeat and Dr. I. D. Grant were appointed chairman and deputy chairman respectively of the Scottish Committee for the session 1948-9.

Organization of Consultants and Specialists in Scotland

153. In the Supplementary Annual Report for 1947-8 the Council reported proposals which had been made for the appointment of a Consultants and Specialists (including Hospitals) Subcommittee of the Scottish Committee, whose duty it would be to consider matters specially affecting those engaged in consultant and specialist practice in Scotland and all questions concerning hospitals. Subsequent events, however, made it apparent that this proposal did not go far enough, and that if consultants and specialists and the Royal Corporations in Scotland were to participate effectively in the machinery established in relation to the National Health Service, there must exist a body with power to determine its own policy on consultant and specialist matters in Scotland, though working within the framework of the Association. There has therefore been constituted a Central Consultants and Specialists Committee (Scotland). This committee largely retains the composition of the former subcommittee of the Scottish Committee, but its reference has been widened to give it power not only to report to the Central Consultants and Specialists Committee in London, on which it is directly represented, but to its constituent bodies, and to negotiate (within any negotiating machinery that may be laid down for the medical profession and in a manner yet to be defined) with the Department of Health for Scotland on matters specially affecting consultants and specialists working under the National Health Service (Scotland) Act. The relationship of the committee to the Scottish Committee of the Association is analogous to the relationship which exists between the Central Consultants and Specialists Committee and the Council.

On behalf of the Association the Council has accepted responsibility for the cost of the working expenses of this committee, including the provision of secretarial and clerical services and the provision of accommodation for meetings. The Scottish Secretary acts as its secretary. The committee has had under consideration various matters arising from the Spens Specialists Report in their relation to Scotland. It has also considered difficulties arising in connexion with (1) the status and remuneration of medical superintendents of hospitals and institutions in Scotland under the National Health Service, (2) interim payments for whole-time consultants and specialists holding dual appointments with a Regional Hospital Board and a university, and (3) status of local authority officers transferred

to the hospital and specialist service. All these matters have been discussed with representatives of the Department of Health for Scotland.

In addition to the appointment of the Central Consultants and Specialists Committee (Scotland) there is being appointed a Scottish Joint Committee of the Royal Scottish Medical Corporations and the Central Consultants and Specialists Committee (Scotland), parallel to the Central Joint Committee. This Joint Committee will have direct contact with the Secretary of State and the Department of Health for Scotland on consultant and specialist matters specifically related to the Scottish Act.

Organization in Respect of General Medical Services under National Health Service in Scotland

General Medical Services Subcommittee (Scotland)

154. Matters arising in connexion with the general medical service under the National Health Service in their specific relation to Scotland will be dealt with by a General Medical Services Subcommittee of the Central General Medical Services Committee. So far as the Scottish Committee of the Association is concerned this subcommittee will be autonomous in its own particular sphere and will report direct to the General Medical Services Committee and through the local medical committees in Scotland to the Annual Conference of Local Medical Committees.

With the authority of the General Medical Services Committee, a conference of representatives of Scottish Local Medical Committees was held on Feb. 10, 1949, at the Scottish House of the Association. The conference was composed of representatives of Scottish local medical committees and members of the General Medical Services Subcommittee (Scotland) under the chairmanship of Dr. W. M. Knox. The object of the conference was to consider: (1) the constitution and method of appointment of permanent local medical committees in Scotland and the desirability of the preparation of a model scheme; (2) the method of central representation of Scottish local medical committees; and (3) other relevant questions pertaining to the National Health Service in Scotland. A report of the conference was published in the *Supplement* of Feb. 26, 1949 (p. 109).

Training of Assistants Scheme

This matter has been discussed with the Department of Health for Scotland, and a scheme which differs in some respects from that set up in England and Wales for the purpose of the training of assistants under the National Health Service has been approved. The main difference is that whereas in England and Wales the selection of "trainer" practitioners is left in the hands of local medical committees, with the addition of a university representative, in Scotland the selection is delegated to committees on a regional basis. These committees are composed of general practitioner representatives nominated by the local medical committees in the regions, consultant and specialist practitioners appointed from a panel selected by the regional consultants and specialists committees in Scotland, with one member appointed by the appropriate university, and an independent chairman appointed by the Secretary of State for Scotland.

Health Centres and Group Practice

155. The general position regarding the provision of health centres and, in particular, the possibility of developing one or more forms of group practice in suitable areas in Scotland is at the present time the subject of discussion with the Secretary of State.

Highlands and Islands and Rural Practitioners

156. The position of Highlands and Islands and rural practitioners in Scotland under the National Health Service is being carefully watched. Notwithstanding the disappearance, under the National Health Service, of the Highlands and Islands Medical Service as such, there remain many problems in the Highlands and Islands (and particularly in the Islands) which differ from those of other rural areas of Scotland. In all cases, however, mileage forms a substantial part of the income and presents an even more difficult problem in Scotland than in England and Wales, as a much larger proportion of practitioners receive mileage payments. Statistics in respect of mileage are

being collected from all rural practitioners, whether Highlands and Islands or otherwise, with a view to determining what would be an equitable distribution of mileage in Scotland.

At the request of the Department of Health and with the assistance of the local medical committees concerned, a list of those practices deemed to have been saleable before July 5, 1948, has been prepared for the consideration of the Practices Compensation Committee in deciding which of those practitioners who formerly received grants under the Highlands and Islands Scheme are entitled to compensation.

Whole-time Medical Officers of Local Health Authorities

157. Proposals for the remuneration of whole-time medical officers of local health authorities under the National Health Service have been considered in their relation to Scotland. The question of Whitley Council machinery for these medical officers has also been considered and is covered in the following paragraph.

Whitley Council Machinery for Persons Employed in the National Health Service

158. Proposals for the establishment of Whitley Council machinery for persons employed in the National Health Service issued by the Ministry of Health and Department of Health for Scotland have been considered in their relation to Scotland. The proposal that there should be established a Scottish Council as an integral part of the Whitley machinery has been abandoned, but there would be nothing to prevent a Medical Functional Council under the general Whitley machinery appointing a Standing Scottish Committee with autonomous powers, if thought advisable.

The Council has agreed that it should be a condition of the Association's acceptance of the Whitley Council machinery (a) that it should cover all doctors employed under the National Health Service Acts, or in the employment of local authorities throughout the United Kingdom, and (b) that it contains provision for a Standing Scottish Committee of the Medical Functional Council, to which shall be referred, when appropriate, matters which require to be specially considered as specifically relating to the Scottish Act. There will also be provision for Scottish representation on any sectional subcommittees of the Medical Functional Council which may be appointed to deal with the various aspects of the National Health Service.

Medical Members of Statutory Bodies under National Health Service (Scotland) Act

159. At the request of the Department of Health for Scotland nominations have been made of medical members for appointment to various standing advisory committees of the Scottish Health Services Council and to the Tribunal appointed under section 43 of the Scottish Act (Disqualification of Persons Providing Service).

Constitution of Scottish Committee

160. The question of whether any alteration is desirable in the constitution of the Scottish Committee as the result of the introduction of a National Health Service operated under a separate Act for Scotland has been considered. In view, however, of the formation of the Central Consultants and Specialists Committee (Scotland) and the General Medical Services Subcommittee referred to in foregoing paragraphs, it is not proposed to make any recommendation for alteration of the constitution of the Scottish Committee. The matter will be reviewed at a later stage in the light of developments.

Fees for Medical Witnesses and for Reports Required by Procurators Fiscal

161. After further discussion with representatives of the Crown Office a revised scale of fees for evidence and reports required by procurators fiscal in Scotland has been approved with operation as from Jan. 1, 1949. The Scottish legal system in this matter differs from that in England. Under the Scottish system the procurator fiscal is in general the Crown official responsible for fees which in England are the responsibility partly of coroners and partly of criminal courts, and for this reason identical scales in the two countries are not appropriate. The scale of fees now adopted, which offers a very substantial increase on the former fees (which had remained virtually unaltered since 1901), is as follows:

Day Allowances

Witnesses acting in a professional or expert capacity .

(a) For attending at precognitions and for making examinations and reports, conducting inquiries and investigations, and giving evidence:

Engaged not more than 2 hours, not exceeding .. £2 2s

[NOTE: This maximum must not be regarded as the normal fee. For short precognitions and attendances, formal certificates, etc., an allowance less than the maximum will often be sufficient.]

Engaged more than 2 hours but not more than 4 hours, not exceeding £3 3s

Engaged more than 4 hours but not more than 8 hours, not exceeding £4 4s

Engaged more than 8 hours £6 6s

(b) For a dissection specially sanctioned by Crown Counsel £3 3s

When more than one dissection is made in one day, for each dissection after the first £2 2s.

In computing the time engaged, time necessarily occupied in travelling shall be included.

Night Allowance

Every witness necessarily detained from home overnight shall be paid a reasonable allowance for subsistence, but not exceeding 20s a night.

This scale has been accepted on the understanding that the Association reserves the right to reopen negotiations on the basis of any revision which may be made in the fees payable in England and Wales under the Coroners Acts.

Departmental Committee on Medical Certificates

162. Information has been collected regarding those certificates which under Scottish law differ from those required under English law, and a statement on the matter has been presented to the Departmental Committee.

Report of Working Party on Midwives

163. A joint committee composed of representatives of the medical bodies in Scotland who have been invited by the Secretary of State to submit their views on the Report of the Working Party on Midwives has been appointed. The object of this joint committee is to prepare for submission to the Secretary of State an agreed statement of the views of the profession in Scotland on the Report.

Public Relations Machinery in Scotland

164. A part-time press officer for Scotland, Mr. George Donaldson, Parliamentary sub-editor of the *Scotsman*, has been appointed. The officer will assist in handling B.M.A. announcements or publicity material issued by the Central Public Relations Committee so far as the Scottish Press, national and local, is concerned. He will also be available to the Scottish Committee and the Scottish Secretary for advice on the means of obtaining the maximum publicity in Scotland for B.M.A. policy.

WALES

165. The Welsh Committee, which meets at Shrewsbury under the chairmanship of Dr. H. R. Frederick, has reviewed its constitution in order that it may more effectively represent the special interests of the profession in Wales. The new constitution would serve to bring the views of members in North Wales and South Wales into closer alignment with one another. The Council has decided to reconstitute the Welsh Committee as follows:

(i) The Officers of the Association *ex officio*;

(ii) Members of the Council representing Wales, including Monmouthshire.

(iii) The Secretaries of North Wales and South Wales and Monmouthshire Branches.

(iv) The Representatives in the Representative Body (or in their absence the Deputy Acting Representatives) of the constituencies in Wales, including Monmouthshire, and the Representatives in the Representative Body (or in their absence the Deputy Acting Representatives) of the Shropshire and Mid-Wales Branch if resident or practising in Wales, with power to co-opt not more than two members for special purposes.

There is a strong desire for the establishment of a Welsh B.M.A. House in Cardiff, and exploratory steps to this end are being taken.

OVERSEAS

Terms of Service in the Colonial Medical Service

166 Comments received from Branches overseas on the interim revisions of remuneration which have been effected in the medical services in various Colonies have made it clear to the Council that in many cases the revised terms are considered to be unsatisfactory. After careful consideration the Council has decided that, rather than undertake further negotiations with the Colonial Office on these interim terms of service, the most practical policy to pursue is to start negotiations for completely new post-war scales of remuneration related to professional income in the United Kingdom. The Council has accordingly reviewed the remuneration and conditions of service of Colonial Medical Officers in the light of the Spens Reports and of the terms which are being negotiated for the National Health Service in Great Britain. Full consideration has been given to the varying levels of taxation and cost of living in the Colonies to the pension schemes at present in force, and to the various advantages and disadvantages of the Colonial Medical Officer's life, and the Council has submitted the following proposals to the Colonial Office as comparable having regard to all the factors to the Spens recommendations:

Standard Scale	£850	£850, £900	£1,000 + £50—£2,000
Superscale Posts	Grade IV		£2,250
	III		£2,500
	II		£3,000
	I		£3,500

In framing these proposals the Council has used the betterment factors laid down by the Ministry of Health in calculating the remuneration of practitioners in the National Health Service. Any increase in these factors will necessitate a corresponding increase in the Council's proposals. The figures include an expatriation element, and are intended to be for whole-time service. The Council considers that the scale should be applicable to all territories but recognizes that in certain Colonies where conditions are peculiar (e.g., Malaya, Hong Kong) it will be necessary for certain salaries in the scale to be supplemented by a local allowance. The Council has submitted to the Colonial Office a memorandum on the remuneration of Colonial Medical Officers (see Appendix VI to this report), and has intimated to the Colonial Office that it wishes to open negotiations on the following other principal matters, besides remuneration, in the Colonial Medical Service: recruitment, personnel management, delay in filling higher appointments, and private practice.

Royal Commission on Health and Population in the African Colonies

167 The Council has sent to the Colonial Office a copy of the memorandum prepared by the Kenya Branch, to which reference was made in the Supplementary Annual Report of Council in 1948, recommending the appointment of a Royal Commission to inquire into the health and population of the African Colonies. The Kenya Branch has insistently drawn attention to the fact that the population of East Africa is rapidly outstripping the available food-supply. The Council is impressed by the gravity of the situation and has asked the Secretary of State to give the matter his earnest consideration.

Reorganization of the Malayan Medical Service

168 The Council of the Malayan Branch has accepted in principle the proposals for the new conditions of service in the unified Malayan Medical Service which were reported by the Council to the Representative Body in 1948. The Branch has made two provisos to its acceptance—(a) that a tribunal be set up to adjudicate on any case where an officer claims hardship and seeks compensation and (b) that means be found to overcome the difficulty of promotion to Grade A Superscale posts the chances of which in the new scheme appear to be halved. Information is awaited regarding the attitude of the Malayan Government to these two provisos. The Council continues to watch with care the negotiations on the unification of the Malayan Medical Service.

Visit to East African Branches

169 In January the Council sent an Assistant Secretary (Dr E. Grey Turner) to visit the Kenya, Sudan, Tanganyika and Uganda Branches. In a tour lasting three weeks the

Assistant Secretary met a large proportion of the members of these Branches addressed a number of meetings, and had discussions with leading members of the Governments of the Colonies visited. His report emphasized the importance of the Association as an Imperial link, embracing all territories and all races, and drew attention to the vital scientific and cultural role which the overseas Branches play in the life of their communities. The Council takes this opportunity of stating that it is fully conscious and proud of the fact that the Association has over 10,000 loyal members overseas and assures these members that their problems and difficulties are and have been very much in its mind despite the immense preoccupations of the Association in the United Kingdom. The Council considers that visits such as that of the Assistant Secretary to East Africa are necessary to unite the overseas Branches to the parent body, and expresses the hope that overseas members on leave in England, especially perhaps those from the smaller overseas Branches will make a point of calling at Headquarters.

Empire Medical Advisory Bureau

170 The Empire Medical Advisory Bureau was opened at B.M.A. House on July 13, 1948, by Lord Addison (Lord Privy Seal) in the presence of a distinguished gathering which included the members of the Advisory Committee. This committee is representative of the various Commonwealth Government Departments and societies interested in the welfare of Empire and overseas visitors.

The Committee of Management has met regularly in connexion with the organization and development of the Bureau. This is now well established and its work has steadily increased month by month.

Up to the end of January, 1949, 500 inquirers had made use of the Bureau either personally or by letter, and 282 of these had made a total of 494 visits to the Bureau.

About three fifths of the inquiries concerned various aspects of postgraduate education and experience including information on courses of instruction, examinations, appointments in and visits to hospitals, and medical registration. One-quarter of the inquiries related to accommodation, and the remaining inquiries—about one-sixth of the whole—extended over the very wide field of general information.

A "Summary of the Regulations for Postgraduate Diplomas and of Courses of Instruction in Postgraduate Medicine" has been prepared and copies have been dispatched overseas to all Branches of the Association, affiliated associations, deans of medical faculties, postgraduate committees, and editors of medical journals, for the information of intending visitors to this country.

Through the kindness and co-operation of port health officers many of the visitors are met on their first arrival in this country by a fellow medical man.

Social functions, at which overseas visitors have the opportunity of meeting fellow practitioners from other parts of the British Commonwealth and members of the profession in this country, including a few of our leading physicians and surgeons, are a regular feature of the Bureau's activities, up to date nearly 500 doctors and wives from overseas have attended "At Homes" arranged by the Bureau.

MEDICAL FILMS

171 The object of the Council is to develop and maintain a library of medical films primarily to serve Divisions and Branches of the Association, and a bureau to act as a central office of information on medical films, their production, appraisal, grading and history. A large amount of detailed inquiry is necessary, and consequently the task is difficult and must be planned as a long term policy. The film library is now in operation, and there has been a considerable demand for its services.

When the work of appraising the films is advanced a catalogue will be prepared and the approved films will be available to borrowers. During the year the Council has purchased an outstanding American film "Angina Pectoris" written and directed by Joseph E. F. Riseman, M.D., Boston, Mass. In addition the following films have been presented to the film library:

The Medical Motion Picture. Eye Surgery—Removal of Intra-ocular Foreign Bodies, presented by the American Medical Association.

Studies in Human Fertility (Medical Methods of Control of Conception), presented by the Ortho-Pharmaceutical, High Wycombe, Bucks.

Curare in the Treatment of Infantile Paralysis, presented by Dr. N. S. Ransohoff, New York.

Muscle Testing, presented by Sir Morton Smart.

A number of films have been made available to the Council for copying, and consideration is being given to the conversion of certain films from silent to sound editions and to their suitability for exchange for films from foreign sources. A 16-mm. Bell and Howell-Gaumont projector has been purchased, and during the year this has enabled a number of medical film demonstrations to be given to local Divisions of the Association. The Council has also approved the production of a film entitled "The Treatment of Infections of the Fingers and Hand," by A. G. Riddell, F.R.C.S., and steps are now being taken to produce the film as soon as possible.

H. GUY DAIN,
Chairman.

APPENDIX I RETURN OF ATTENDANCES OF COUNCIL

Name	Attendances

APPENDIX II

DUTIES OF AND ETHICAL RULES FOR INDUSTRIAL MEDICAL OFFICERS*

I. Duties

The duties which form the basis of the industrial medical officer's work vary considerably according to the needs of the occupational group in which he works. The following duties may be properly undertaken by industrial medical officers:

- (i) Examination of applicants for employment and advice as to their placement.
- (ii) Immediate treatment of medical and surgical emergencies occurring at the place of employment.
- (iii) Examination and continued observation of persons returning to work after absence due to illness or accident, and advice on suitable work.
- (iv) Health supervision of disabled persons.
- (v) Periodical examination of persons exposed to special hazards in respect of their employment.
- (vi) Maintenance of the efficiency of the nursing and first-aid personnel and equipment.
- (vii) The study of the work and working environment and their effects on the health of the employees.
- (viii) Advice to managements regarding:
 - (a) The working environment in relation to health.
 - (b) Occurrence and significance of hazards.
 - (c) Accident prevention.
 - (d) Statutory requirements in relation to health.

(ix) Health supervision of all employees with special reference to (a) young persons, (b) married women, and (c) elderly persons.

(x) Medical inspection of canteen facilities and medical supervision of the health and hygiene of canteen workers.

(xi) Advice to those committees within the factory which are responsible for the health, safety, and welfare of the employees.

(xii) The arranging and carrying out of such educational work in respect of the health and fitness of the employees as may be desirable and practicable.

(xiii) Advice to employees on all health matters relating to their work or working capacity.

ADVISORY NOTE

The industrial medical officer is advised to establish contact with other industrial medical officers and, where possible, with University Departments of Occupational Health and Government Departments concerned with the health of industrial workers. The latter include the Factory Department of the Ministry of Labour, which has on its staff a number of Medical Inspectors of Factories. The name and address of the Local Medical Inspector of Factories may be obtained from the District Inspector of Factories.

The Medical Research Council, at 38, Old Queen Street, London, S.W.1, has a number of special committees dealing with various aspects of industrial health research. Its work in this field is co-ordinated by the Industrial Health Research Board, and inquiries on research problems may be sent to the Secretary at the above address.

The Universities of Durham and Manchester have departments of industrial or occupational health, and the University of Glasgow a sub-department of occupational health, from which advice may be obtained. From time to time some of these departments conduct short courses of instruction in industrial medicine and hygiene.

II. Ethical Rules

Subject to statutory requirements these rules shall, where existing ethical rules or custom fail to cover the circumstances, govern the professional relationships of industrial medical officers with their medical colleagues in other branches of medical practice, with those employees under their professional care, and with managements. The rules apply not only to whole-time officers but also to those employed part-time or in any other capacity.

1. (i) When an industrial medical officer renders advice or treatment to an employee at the place of employment, and

*These Duties and Rules replace those approved by the Representative Body in 1937.

when in the employee's own interests he deems it advisable, he shall inform the employee's own doctor of the material facts.

(ii) When an industrial medical officer finds on examination that an employee is unfit for work, he shall advise the employee to consult his own doctor or he may, in emergency, send him direct to hospital.

(iii) If an employee is under the care of his own doctor or of a hospital, and if at the place of employment there are special facilities and equipment for continuing treatment, the industrial medical officer may arrange for such treatment with the approval of the doctor or hospital concerned.

2. When in the course of an examination of an employee for superannuation purposes, retirement or special duty, material clinical findings come to light, the industrial medical officer should with the consent of the person examined inform his doctor of the relevant details.

3. Except in emergency, an industrial medical officer shall not undertake any treatment that is normally the responsibility of the employee's own doctor, unless it be with his agreement.

4. In his capacity as industrial medical officer he shall not undertake treatment of any member of an employee's family who is not employed at the same place of work.

5. A part-time industrial medical officer shall not utilize his position to influence an employee to choose him as his medical attendant.

6. An industrial medical officer shall not, except in emergency, or where a prior understanding with local practitioners exists, send any employee direct to hospital. When he considers that attendance at hospital is necessary or advisable, he shall refer the employee to his own doctor, to whom he may make a suggestion to this effect. When, in an emergency, an industrial medical officer sends an employee to hospital, he shall inform the relatives of the patient is likely to be detained) and also the employee's own doctor, where known.

7. When an industrial medical officer is asked by his management to report on the condition of an employee who is absent from work for health reasons and under the care of his own doctor, the industrial medical officer, before examining the patient, shall first communicate with the employee's doctor, informing him of the time and place of his intended examination.

8. An industrial medical officer should, whenever possible, respond to an invitation for consultation with an employee's own doctor.

9. An industrial medical officer shall not carry out any personal preventive measure which is purely experimental without the consent of the employee, and, where desirable, the consent of the employee's own doctor.

10. The personal medical records of employees maintained by an industrial medical officer for his professional use are confidential documents. Access to them must not be allowed to any other person except with the consent of the industrial medical officer or with the consent of the employee concerned.

An industrial medical officer shall at all times be responsible for the safe custody of his records. On the termination of his appointment he shall hand over his records only to the industrial medical officer who shall succeed him in the appointment.

If there is no successor to his appointment, the industrial medical officer retains his responsibility for the safe custody of his records or for their destruction.

11. An industrial medical officer shall not disclose his knowledge of industrial processes acquired by virtue of his appointment except with the permission of his management or when so required in courts of law.

12. When an industrial medical officer has examined an applicant for employment, and as a result of the examination employment is subsequently refused, the industrial medical officer may disclose his decision to the applicant and, when authorized, may disclose the findings to his own doctor.

ADVISORY NOTES

(1) When an industrial medical officer addresses a communication to the employee's own doctor and receives no reply within a reasonable time, he shall be at liberty to assume that the employee's own doctor takes no exception to the contents of his communication. It is important in the employee's interest that no opportunity of useful co-operation between the employee's doctor and the industrial medical officer should be neglected. Such co-operation may be of particular value when an employee is under treatment for an occupational

disease of which the industrial medical officer has special experience.

(2) Industrial medical officers should not make statements as to liability in the case of accidents at the place of work except when so required in courts of law.

APPENDIX III

DUTIES OF AND ETHICAL RULES FOR INDUSTRIAL MEDICAL OFFICERS

(As approved by the Representative Body in 1937)

I. Duties

The duties which form the basis of the industrial medical officer's work vary considerably according to the needs of the individual industry or commercial organization. In the following paragraphs are set out the duties which may properly be undertaken by industrial medical officers when so required:

(i) Examination of applicants for employment and advice as to their selection.

(ii) Immediate treatment of medical and surgical emergencies occurring at the place of employment.

(iii) Examination of persons returning to work after illness or incapacity.

(iv) Periodical examination of persons exposed to special hazards.

(v) Responsibility for the efficiency of the nursing and first-aid personnel and equipment.

(vi) Advice to the management regarding:

(a) The hygiene of the factory.

(b) The health conditions of the workers.

(c) The occurrence and risk of dangerous hazards.

(d) The accident prevention arrangements.

(e) Factory legislation concerning health and safety and the special diseases to which the particular industry exposes any worker.

(vii) Maintenance of close touch with the management with a view to ensuring that conditions are such as to produce the highest degree of mental and physical welfare of the workers.

(viii) Continued observation of all young persons with a recommendation, where necessary, for the provision of free meals or milk.

(ix) Continued observation of all persons returning to work after prolonged illness.

(x) The medical supervision of canteens to ensure the cleanliness, good quality, and physiological adequacy of the food.

(xi) Advice to the works councils, welfare departments, benevolent fund committees, etc., on any matter affecting the health of the workers.

(xii) The arranging and carrying out of such educational work in respect of the health and fitness of the workers as may be desirable and practicable.

(xiii) Ready accessibility to employees for medical advice upon matters relating to their work.

(xiv) Encouragement of supervisors to report signs of ill-health in any of their workers.

(xv) Advice to the management regarding fire and air-raid precautions.

II. Ethical Rules

Subject to statutory requirements these rules shall, where existing ethical rules or custom fail to cover the circumstances, govern the professional relationships between medical officers attached to industrial and commercial concerns, their colleagues in general practice, and the workers and staff under their professional care and charge. The rules apply not only to whole-time officers but to those employed part-time or in a casual consultative capacity.

1. In carrying out their duties industrial medical officers shall be guided generally by the following ethical code:

(i) The industrial medical officer shall render such emergency or first-aid treatment as is required at the place of employment, and shall inform the worker's own doctor of any treatment given. Where further treatment is deemed necessary, the worker shall be instructed to consult his own practitioner.

(ii) Where there are special facilities or equipment and suitable transport arrangements are available, if it is in the interests of the patient, continuing treatment may be given at the factory clinic with the consent of, and in consultation with, the worker's own practitioner. In these cases some such form as the following should be used:

"Date

Dear Sir,

Re:

Address

This patient has been sent home and advised to consult you. Should you consider that the special facilities of this clinic would be useful for the purpose of applying dressings or carrying out such treatment as you desire, I shall be pleased to arrange for this if you will instruct the patient to report to me.

Yours faithfully,

..... Medical Officer.

Remarks by patient's own doctor

This note may be handed back to the patient."

(iii) In cases where the industrial medical officer considers that by attending at the factory clinic for dressings or special treatment instead of obtaining such treatment elsewhere the worker might be saved loss of time and/or employment, he shall communicate with the worker's own practitioner and offer the facilities of his clinic.

(iv) The industrial medical officer shall not provide treatment in cases of disability, save in such instances as may be covered by an understanding with a committee representative of the local medical profession or where there is an *ad hoc* agreement with the worker's own practitioner. Such treatment shall be given only with the consent of the worker.

(v) The industrial medical officer shall consider and advise upon the occupation of any worker whose duties appear to be too heavy or otherwise unsuitable, and, where necessary, he shall consult the worker's own doctor.

(vi) The industrial medical officer shall (a) examine and advise concerning those workers engaged in hazardous or arduous occupations; also those about to be transferred to heavy or dangerous occupations, and shall communicate with the worker's own medical attendant at the earliest opportunity; and (b) examine and report to the works management upon those workers who appear suitable for early pension or retirement or in regard to the continuance of invalidity payments.

(vii) The industrial medical officer shall not carry out domiciliary treatment.

(viii) A whole-time industrial medical officer shall not treat any member of the worker's family who is not employed at the factory

(ix) A part-time industrial medical officer shall not utilize his position to influence the worker to choose him as medical attendant or family doctor.

(x) The industrial medical officer shall not, except in an emergency, or where a prior understanding with the local practitioners is in operation, send any employee direct to hospital. Where he considers attendance at hospital to be necessary or advisable, he shall refer the employee to his own medical attendant and may make a suggestion to this effect to the latter.

Where, in an emergency, the industrial medical officer sends a worker to hospital, he shall advise: (a) the relatives (if the patient is detained); and (b) the worker's medical attendant.

(xi) Where an industrial medical officer has occasion to examine and to report to the management concerning the condition of any worker who is absent from his employment on account of illness and is being treated by his own medical attendant, he shall conform to the Ethical Rules for Medical Inspectors laid down by the Association. In this connexion an industrial medical officer shall, with the consent of his employer, place his special knowledge at the disposal of the attending practitioner, and *vice versa*.

(xii) The industrial medical officer should, where possible, respond to any invitation to meet the worker's practitioner in consultation.

(xiii) Except in emergency the industrial medical officer shall not carry out any individual preventive measure without the individual consent of the worker and prior agreement

with the worker's medical attendant. He shall in no way associate himself with experiments which involve the active participation of the workers without their consent and the prior notification of the workers' doctor.

(xiv) The medical records of the workers maintained by the industrial medical officer are confidential documents; they must remain in the custody of the industrial medical officer or of his deputy. Access to them must not be allowed to any other person save only to another registered medical practitioner, and then only at the request or with the consent of the worker.

(xv) The industrial medical officer shall at all times be responsible for the safe custody of his medical records. On terminating his appointment he shall make arrangements for the safe custody of his records until such time as it is possible to hand them over to his successor.

2. Where nurses are employed by the management the industrial medical officer shall instruct them to maintain the proper ethical code for nurses. Any professional matter must be treated as confidential and disclosed only to the industrial medical officer or to the worker's own medical attendant.

3. The term "consultation" in these rules shall be understood to include a written or telephonic communication addressed by the industrial medical officer to the medical attendant. In the absence of a reply within a reasonable time the industrial medical officer shall be at liberty to assume the other doctor's agreement.

APPENDIX IV

AMENDMENTS OF ARTICLES AND BY-LAWS

(i) *Article No. 1.*—By deleting the figures "1929" and by substituting therefor the figures "1948."

(ii) *Article No. 4 (1).*—By inserting before the word "voting" the words "receiving notices of General Meetings or of."

(iii) *Article No. 22.*—By deleting this Article and by substituting therefor the following new Article to be numbered 22:

"22. The Association shall in each calendar year hold a General Meeting as its Annual General Meeting in addition to any other meetings in that year. Not more than fifteen months shall elapse between the date of one Annual General Meeting and that of the next. The Annual General Meeting shall be held at such time and place as may be fixed by the Council, and if no time is so fixed, shall be held on Oct. 20 (or if that day be a Sunday on Oct. 21), and if no place is so fixed shall be held at the registered office of the Association."

(iv) *Article No. 24.*—By deleting this Article and by substituting therefor the following new Article to be numbered 24:

"24. The Council may whenever it thinks fit and (without prejudice to the provisions of the Companies Act, 1948) it shall upon a requisition made in writing as hereinafter provided by any one hundred or more Members convene an Extraordinary General Meeting."

(v) *Article No. 25.*—By deleting this Article and by substituting therefor the following new Article to be numbered 25:

"25. A requisition must state the objects of the meeting and must be signed by the requisitionists and deposited at the registered office of the Association, and may consist of several documents in like form each signed by one or more requisitionists."

(vi) *Article No. 26.*—By deleting this Article and by substituting therefor the following new Article to be numbered 26:

"26. If the Council does not within twenty-one days from the date of the deposit of a requisition proceed duly to convene an Extraordinary General Meeting, the requisitionists, or any one hundred of them, may themselves convene a meeting for the objects specified in the requisition, but any meeting so convened shall not be held after the expiration of three months from the said date. A meeting convened by the requisitionists shall be convened in the same manner, as nearly as possible, as that in which the General Meetings are to be convened by the Council."

(vii) *Article No. 27.*—By deleting this Article and by substituting therefor the following new Article to be numbered 27:

"27. In the case of an Annual General Meeting or of a meeting for the passing of a Special Resolution twenty-one clear days' notice at the least and in any other case fourteen clear days' notice at the least specifying the place, the day, and the hour of meeting, and in the case of special business the general nature of such business (and in the case of an Annual General Meeting specifying the meeting as such) shall be given in manner hereinafter mentioned to all the Members (other than those who under the provisions of the Regulations and By-laws are not entitled to receive the notice) and to the Auditors for the time being of the Association. The accidental omission to give notice to, or the non-receipt of notice by, any person entitled to receive notice shall not invalidate the proceedings at any General Meeting."

(viii) *Article No. 41.*—By deleting this Article and by substituting therefor the following new Articles to be numbered 41 (a) and 41 (b) respectively:

"41 (a). The Council shall be composed of the President of the Association, the President-Elect, the immediate Past-President, the Chairman of the Representative Body, the Chairman and (during the year immediately following his period of office as Chairman of Council) the Past Chairman of Council, the Chairman of the General Medical Services Committee, the Chairman of the Central Consultants and Specialists Committee, and the Treasurer, *ex officio*, and of members of the Association elected by the bodies and in the manner prescribed in that behalf by the By-laws."

"41 (b). No Member of Council shall vacate or be required to vacate his office as a Member of Council on or by reason of his attaining or having attained the age of 70 and any Member of Council returning or liable to retire under the provisions of the Regulations or the By-laws and any person proposed to be elected or appointed a Member of Council shall be capable of being re-elected or reappointed or elected or appointed, as the case may be, as a Member of Council notwithstanding that at the time of such re-election or re-appointment or election or appointment he has attained the age of 70, and no special notice need be given of any resolution for the re-election or reappointment or election or appointment or approving the election or appointment as a Member of Council of a person who shall have attained the age of 70, and it shall not be necessary to give to the Members notice of the age of any Member of Council or person proposed to be re-elected or reappointed or elected or appointed as such."

(ix) *Article No. 50.*—By deleting this Article and by substituting therefor the following new Articles to be numbered 50 (a), 50 (b), and 50 (c) respectively:

"50 (a). The Council shall once at least in every calendar year lay before the Association in General Meeting an Income and Expenditure Account for the period since the preceding account, made up to a date not earlier than the date of the meeting by more than nine months. The Council shall also cause to be made out in every calendar year and to be laid before the Association in General Meeting a Balance-sheet as at the date to which the Income and Expenditure Account is made up. Every such Balance-sheet shall be signed on behalf of the Council by two of the Members of Council and shall have attached to it a report by the Council with respect to the state of the Association's affairs and the amount, if any, which they propose to carry to reserves. It shall also have attached to it the Auditors' report and such other documents as shall be required by the Statutes to be annexed thereto."

"50 (b). The Council shall also annually prepare an Estimate of the probable income and expenditure of the Association for the coming year and a Report of the proceedings of the Association for the past year and the Balance-sheet and Income and Expenditure Account and the said Estimate and Reports of the Council shall be presented to the Annual Representative Meeting."

"50 (c). A copy of each of the said documents shall be sent to the Secretary of every Branch and Division and published in the *Journal* not less than twenty-two days before the Annual General Meeting."

(x) *Article No. 51.*—By deleting from this Article the words "In addition to the above-mentioned Report."

(i) *By-law No. 10.*—Insert before the words "any vote" the words "receive notices of General Meetings or to."

(ii) *By-law No. 12.*—Insert before the words "any vote" the words "receive notices of General Meetings or to" and insert before the word "voting" the words "receiving notices of General Meetings or of."

(iii) *By-law 16 (1).*—(i) In line 1 delete the figures "1923" and substitute therefor the figures "1950." (ii) In line 5 delete the word "three" before "guineas" and substitute therefor the word "four." (iii) In Column 1 under the heading B (iii) insert the word "non-professional" between the words "whole time" and "member," and delete the words "or Government Department." (iv) In Column 2 of the table opposite each of the headings A, B (iii), and B (iv) in Column 1 insert after the

Name of Committee	Additional Members <i>ex officio</i>	Appointed Members			Duties Powers, etc
		By the Representative Body	By the Council	Otherwise Appointed	
General Medical Services	The chairman for the time being of the Conference of Representatives of Local Medical Committees called by the General Medical Services Committee of the British Medical Association	—	—	Registered medical practitioners appointed as follows: 6 such practitioners (being members of the Association) elected (in the manner prescribed by the Representative Body) by Representatives of the Constituencies formed for Great Britain and Northern Ireland under By-law 39, namely, 4 by all the Representatives (acting together) of the Constituencies so formed for England and Wales, 1 by all the Representatives (acting together) of the Constituencies so formed for Northern Ireland, and 1 by all the Representatives (acting together) of the Constituencies so formed for Scotland, together with 43 practitioners (whether members of the Association or not) to be nominated or elected as under, <i>viz</i> : 33 to be elected so far as possible on a territorial basis by the Local Medical Committees formed in Great Britain under the National Health Service Act, and by Local Medical Committees formed in Northern Ireland under the <i>Health Services Act (Northern Ireland)</i> , 1948; 6 to be elected by the Annual Conference of Representatives of Local Medical Committees; 2 to be nominated by the Central Consultants and Specialists Committee; 1 to be nominated by the Medical Women's Federation; 1 to be nominated by the Society of Medical Officers of Health; 1 by the Central Consultants and Specialists Committee; 1 by the Public Health Committee; 1 by the General Medical Services Committee	To deal with all matters affecting practitioners providing general medical services under the National Health Service Act and any Act amending or consolidating the same and to watch the interests of those practitioners in relation to those Acts. The Committee shall have power to co-opt up to 4 members, if necessary, to secure a representation of a particular class of experience not otherwise represented on the Committee
Private Practice			4		To consider and report on matters affecting the profession in the field of private practice not specially referred to other Committees. The Committee shall have power to co-opt three members

words "two guineas" the words "and a half." In Column 2 of the table opposite heading B (v) in Column 1 delete the words "four guineas and a half" and substitute therefor the words "five guineas." In Column 2 of the table opposite heading B (vi) in Column 1 delete the words "one guinea and a half" and substitute therefor the words "two guineas."

(iv) *By-law No. 23 (1) (a).*—Delete "22" and substitute therefor "37" and delete "12" and delete all the words after the word "belongs."

(v) *By-law No. 44 (3).*—Delete "twenty-two" and substitute therefor "thirty-seven."

(vi) *By-law No. 47.*—Delete "to consider the Annual Financial Statement and Balance-sheet presented by the Council; to consider Reports of the Council" and substitute therefor "to consider the Balance-sheet, Income and Expenditure Account, Estimate, and Reports presented by the Council; to consider."

(vii) *By-law No. 53 (a).*—Delete "twenty-two" and substitute therefor "thirty-seven."

(viii) *By-law No. 53 (b).*—Delete "eight" and substitute therefor "seven."

(ix) *By-law No. 53.*—Delete subparagraph (c) and amend the lettering of all subsequent subparagraphs.

(x) *By-law 53 (d).*—Delete the whole subparagraph and substitute therefor: "Thirteen being persons who have been members of the Association for at least the period aforesaid, at the Representative Meeting being elected as to two by the elected Representatives of the constituencies comprised in the Branches and Divisions in Scotland and as to a further one by the elected Representatives of constituencies comprised in the Branches and Divisions in Wales, including Monmouthshire, and as to the remaining ten by the Representative Body as a whole. All such elections shall be carried out at such time and in such manner as the Representative Meeting may decide."

(xi) *By-law No. 55 (1).*—Delete "twenty-two" and substitute therefor "thirty-seven."

(xii) *By-law No. 56 (1).*—Delete "eight" and substitute therefor "seven."

(xiii) *By-law No. 57.*—Delete and amend the numbering of all subsequent By-laws and all cross references in other By-laws.

(xiv) *By-law No. 58.*—Delete "twenty-two" and substitute therefor "thirty-seven."

(xv) *By-law No. 59.*—Delete "twenty-two" and substitute therefor "thirty-seven."

(xvi) *By-law No. 61 (1).*—Delete the words "in Great Britain and Northern Ireland" and substitute for such last-mentioned words "provided that the term of office of all members of the Council elected at the Representative Meeting shall expire at the close of the Annual Representative Meeting next following the date of their election," and all the words from and including the words "Provided that" to the end of the subparagraph.

(xvii) *By-law No. 61 (2).*—Delete all the words from and including the words "provided that" to the end of the subparagraph.

(xviii) *By-law No. 61 (4).*—Delete the whole of this subparagraph.

(xix) *By-law No. 70.*—Delete all the words from and including the words "the said Chairman" to the end of the By-law and substitute therefor "neither the Chairman nor the Deputy Chairman of the Representative Body shall while holding office as such Chairman or Deputy Chairman (as the case may be) act personally as the representative of any Constituency, but the Constituency which such Chairman or Deputy Chairman represents at the time of his election to the said office shall, during such time as he holds the said office, be represented by a deputy elected in manner provided by By-law 43."

(xx) *By-law No. 72.*—Delete "and for one year thereafter."

(xxi) *By-law No. 79.*—Delete the whole By-law and substitute therefor "Each Standing Committee shall appoint a Member of the Committee as Chairman, provided that, if the Member appointed as Chairman is not a Member of Council, the Committee shall appoint from among its own number a Member of Council as Deputy Chairman."

Schedule to the By-laws

Opposite the headings "Arrangements" and "Public Health." Delete "General Practice" and substitute therefor "Private Practice."

Opposite the headings "Central Consultants and Specialists," "Finance," and "Occupational Health." Delete "General Practice" and substitute therefor "Private Practice." Delete "Insurance Acts" and substitute therefor "General Medical Services."

Opposite the heading "Welsh." Delete from the column "Additional Members *ex officio*" the words "The Chairman and Secretaries of the Welsh Standing Contract Practice Subcommittee" and substitute therefor "The Representatives (or in their absence the Deputy Representatives) of the Constituencies in Wales (including Monmouthshire). The Representatives (or in their absence the Deputy Representatives) of the *Shropshire and Mid-Wales Branch* if such Representatives or Deputy Representatives, as the case may require, are resident and practising in Wales."

Delete all the words appearing in the column "Appointed Members Otherwise Appointed."

Headings "General Practice" and "Insurance Acts." Delete these headings and everything appearing opposite them.

Insert new headings and entries as shown in the Table on p. 203 as to "General Medical Services" immediately below "Finance" and as to "Private Practice" immediately below "Organization."

APPENDIX V

MEMORANDUM ON THE REMUNERATION OF MEDICAL OFFICERS OF THE ARMED FORCES

1. The Association has repeatedly stated (notably at the Annual Representative Meeting at Cambridge in June, 1948) that it would be necessary to review the remuneration of the medical officers of the Armed Forces in the light of the two Spens Reports. It is the Association's view that remuneration in the medical branches of the Armed Forces must conform broadly to that of medical practitioners in civil practice. The Spens Reports have laid down ranges of income which are recognized both by the Ministry of Health and by the Association, and which have been adopted by the Government as the basis for the remuneration of medical practitioners in the National Health Service. The Association has now completed its review and desires to present to the Ministry of Defence the results of its investigation.

2. It is well known to the Association that voluntary entry to the medical branches of the Armed Forces has lately been far from satisfactory. There is no need to point out that this position will deteriorate still further if the terms and prospects in the Armed Forces remain markedly inferior to those in civil medical practice.

3. In comparing the remuneration of medical officers of the Armed Forces with the recommendations of the two Spens Committees an immediate practical difficulty arose. The remuneration of medical officers of the Armed Forces must necessarily be on a scale related to age, service, and rank. The incomes of civilian medical practitioners, on the other hand, are not in general determined by age and length of service, but depend upon a number of factors, including the locations and types of their practices, into which there enters a large element of personal choice. The Association was therefore faced with the problem of translating the recommendations of the Spens Committees into some sort of an age and service scale. In the case of the specialist Spens Report this was relatively easy, because the recommendations are related to some extent to age. In the case of the general practitioner Spens Report a scale was prepared by setting out the arithmetic means of the incomes recommended for the various age groups in Table C of the Report. Above the age of 50 the arithmetic means of the higher incomes recommended in Table C were set out, because it was recognized that the majority of officers of those ages have been promoted to higher ranks by selection.

4. In both cases the net figures of the Reports were adopted, because it was recognized that the practice expenses of a

medical officer in the Armed Forces are not in general borne by himself. The betterment factors adopted by the Ministry of Health in translating the 1939 figures of the Spens Reports into present-day figures were used by the Association for this review, although it must be emphatically stated that the Association has never agreed that these factors reflect in any way accurately or adequately the change in the value of money for the professional classes which has taken place since 1939. Negotiations are at present proceeding on the betterment factor. Any increase which may result in the betterment factor will of course necessitate a corresponding increase in the Association's proposals contained in paragraph 8 below.

5. The Spens figures, increased in respect of betterment, were reduced by 6% for the purposes of this review, in order to take account of the fact that practitioners in the National Health Service must contribute 6% of their net remuneration towards superannuation, while the pensions of Armed Forces medical officers are non-contributory.

6. The figures for the remuneration of medical officers in the Armed Forces which the Association has compared with the recommendations of the Spens Committees were consolidated figures of pay and all allowances of a married officer. This was done because it was recognized that the Spens recommendations made no extra provision for marriage and that civilian practitioners are, in general, responsible for all their living expenses. The Association makes no recommendations for any alterations in the existing system and scale of allowances, as these are common to all officers of the three Services, but confines itself to proposals for increases in the basic pay of medical officers.

7. In comparing the remuneration of Armed Forces medical officers with that of civilian practitioners there are several factors to which great weight must be attached. These are: (a) frequent moves; (b) service in countries ill provided with the amenities of civilized life to which officers are accustomed in the United Kingdom, and sometimes in climates which are arduous and disagreeable; (c) maintenance of two homes for the purpose of educating growing children in the United Kingdom, which may involve heavy expenditure on travelling; and (d) payment of income tax at the British rate irrespective of rates of exchange and the local cost of living. The Association considers that there should be adequate compensation included in the remuneration of medical officers in the Armed Forces to offset these factors, and the figures proposed by the Association include this element.

8. The Association, therefore, as a result of its review, proposes the following rates of basic pay for general duty medical officers:

Rank	Daily Rate £ s.	Increase over Present Rate
Acting Surg. Lieut., Lieut., F.O.	1 5	3s.
Surg. Lieut., Capt., Fl. Lieut.	1 11	3s.
Do. After 2 years as such	1 17	6s.
Do. " 4 " "	2 3	9s.
Do. " 6 " "	2 9	12s.
Surg. Lieut. Com., Major, Sq. Ldr.	2 18	15s.
Do. After 2 years as such	3 4	15s.
Do. " 4 " "	3 7	15s.
Do. " 6 " "	3 10	15s.
Surg. Com., Lieut.-Col., Wing. Com.	3 16	18s.
Do. After 2 years as such	3 19	18s.
Do. " 4 " "	4 2	18s.
Do. " 6 " "	4 5	18s.
Do. " 8 " "	4 8	18s.
Surg. Capt., Col., Group Capt.	4 19	24s.
Do. After 2 years as such	5 2	24s.
Do. " 4 " "	5 5	24s.
Do. " 6 " "	5 8	24s.
Surg. Capt., Brig., Air Cdre.	5 14	27s.
Surg. Rear-Admiral, Maj.-Gen., Air Vice Marshal	6 8	18s.
Surg. Vice-Admiral, Lieut.-Gen., Air Marshal	7 10	15s.

9. The Association considers that a difference between the remuneration of general duty officers and specialists as great as the difference between the recommendations of the Spens Committees for remuneration of general practitioners and specialists would be inappropriate in the Armed Forces. The Association considers, for example, that there should be no marked discrepancy in the remuneration of two officers of equal rank who are carrying out different tasks—e.g., between the remuneration of a major filling an appointment as surgical specialist and a major commanding a company of a field

ambulance. It is considered, however, that specialist pay should be greater than it is at present, and further that the system of payment of specialists should be made uniform in the three Services. The Association recommends that it should be payable at the rate of 6s. a day for graded specialists and 9s. a day for full specialists.

10. The Association proposes that the new scales of remuneration should have effect from July 5, 1948. This was the date on which the National Health Service came into operation, and is clearly the appropriate date for the introduction of related terms of service in the Armed Forces.

11. In conclusion it must be stated that the Association's proposals represent the minimum which can be regarded as comparable with the terms and prospects of medical practitioners in civil life. No attempt has been made to emulate the maximum of £5,200 recommended in the specialist Spens Report. In drawing up its proposals the Association has used only average figures recommended for the incomes of general practitioners. The Association's proposals are therefore modest, and it can confidently be asserted that nothing less will be sufficient to attract recruits in competition with the National Health Service.

APPENDIX VI

MEMORANDUM ON THE REMUNERATION OF OFFICERS OF THE COLONIAL MEDICAL SERVICE

1. At the conclusion of the 1939-45 war it became clear to the British Medical Association that salaries of Colonial Medical Officers were seriously inadequate. Numerous and bitter complaints from members all over the Colonial Empire indicated that these salaries were seriously insufficient in view of the universal rise in the cost of living brought about by the war. The Association represented to the Colonial Office that interim percentage increases of salary should be granted, pending a full review of the remuneration of Colonial Medical Officers in the light of the terms which would be negotiated and laid down for the National Health Service at home. The Colonial Office agreed that increases were necessary, and, as a result of investigations carried out by various Commissions post-war increases of remuneration of members of the Colonial Service, medical and non-medical, have been put into effect. The Association has learned from its members that these increases are considered in many cases to be unsatisfactory and inadequate.

2. Quite apart from these interim post-war increases, the Association has repeatedly stated (notably at the conference at the Colonial Office on Jan. 9, 1948) that it would be its duty to undertake a thorough review of the remuneration of the Colonial Medical Service in the light of the two Spens Reports, when published. It is the Association's view that remuneration in the Colonial Medical Service must conform broadly to the remuneration of medical practitioners in this country. The Spens Reports (which have now been published) have laid down standards which are recognized both by the Ministry of Health and by the Association, and which have been adopted by the Government as the basis for the remuneration of medical practitioners in the National Health Service. The Association has now completed its review of the remuneration of the Colonial Medical Service in the light of the Spens Reports, and desires to present to the Colonial Office the results of its investigation.

3. The Association is fully aware that the terms of service of the Colonial Medical Service are not controlled exclusively by the Colonial Office, and that it is necessary for the latter to secure the agreement of individual Colonial Governments to any changes proposed. The Colonial Office carries a heavy responsibility, however, in that it is the agency by which doctors from Great Britain are recruited to the Service. There is no need to point out that the recruitment position will deteriorate if the terms and prospects in the Colonial Medical Service remain inferior to those in medical practice in the United Kingdom.

4. In comparing the remuneration of Colonial Medical Officers with the recommendations of the two Spens Committees, an immediate practical difficulty arose. The remuneration

of Colonial Medical Officers must necessarily be on a scale related to age and service. The income of a medical practitioner in the United Kingdom, on the other hand, is not in general graded in proportion to age and length of service, but depends upon a number of factors, including the location and type of his practice, into which there enters a large element of personal choice. The Association was therefore faced with the problem of translating the recommendations of the Spens Committees into some sort of an age-and-service scale. In the case of the specialist Spens Report this was relatively easy, because the recommendations are related to some extent to age. In the case of the general practitioner Spens Report, which was the more important for the purposes of this review, a scale was prepared by setting out the arithmetic means of the incomes recommended for the various age groups in Table C of the Report.

5. In both cases the net figures of the Reports were adopted, because it was recognized that the Colonial Medical Officer's practice expenses are not borne by himself. The betterment factors adopted by the Ministry of Health in translating the 1939 figures of the Spens Reports into present-day figures were used by the Association for this review, although it must be emphatically stated that the Association has never agreed that these factors reflect in any way accurately or adequately the change in the value of money for the professional classes which has taken place since 1939.

6. In comparing the remuneration of Colonial Medical Officers with that of practitioners in the home country, there is one important factor to which great weight must be attached. This is the fact that many Colonial Medical Officers live and work outside their home country. They live remote from their relations and from the surroundings in which they have been brought up, usually in countries which are ill provided with the amenities of civilized and sophisticated life such as are commonplace in Great Britain, and often in climates which are arduous and disagreeable. Further, Colonial Medical Officers must be prepared to undergo relatively frequent moves, and are generally faced with the expense of educating their children in the United Kingdom and perhaps with the necessity of maintaining two homes. The Association is aware that these heavy disadvantages are to some extent offset by the relatively low level of taxation in the Colonies. The Association has had before it figures of taxation levels in the principal Colonies and has given due weight to this factor. Figures of the cost of living have also been considered, however, and it is clear that in some cases the cost of living substantially reduces the advantage conferred by lower taxation. After careful consideration the Association concludes that the remuneration of Colonial Medical Officers recruited outside the countries in which they serve must include an adequate expatriation element to offset the disadvantages of their career.

7. The Association, therefore, as a result of its review, proposes the following scale of pensionable remuneration, which should be applicable to medical officers serving in all Colonies and Dependencies:

Standard Scale.—£850, £850, £900 (probationary period of two-three years), £1,000 × £50 to £2,000. (The top of this scale will be attained, in the absence of promotion to a superscale post, before the minimum retiring age is reached. Efficiency bars should be retained.)

Superscale Posts.—Grade IV, £2,250; Grade III, £2,500; Grade II, £3,000; Grade I, £3,500.

8. The Association considers that locally recruited medical officers should receive the above salaries less a proportion to be negotiated. The Association is aware that in some instances the salaries now proposed are lower than those which are actually in force. There is no suggestion that the remuneration of medical officers at present serving should be reduced as a result of the introduction of the Association's proposals, and, furthermore, it will be necessary in certain Colonies (such as Malaya and Hong Kong) to supplement the proposed salaries with a local allowance to meet peculiar local conditions. The Association considers that such local allowances, which would be payable to European and locally recruited officers, should be non-pensionable.

9. It is considered that medical practitioners entering the Colonial Medical Service should be eligible to receive increments above the starting salary in respect of special qualifica-

tions or experience. The Association has noted with satisfaction a proposal similar to this in paragraph 53 of the Report of the Harragin Commission and in paragraph 133 of the Report of the Holmes Commission.

10. The salaries proposed are based on the assumptions that the medical officer will be responsible for paying rent for his housing accommodation, and that they are for full-time employment.

11. The Association is aware that the process of abolishing private practice by Colonial Medical Officers has begun. The speed and character of this process must clearly depend upon local circumstances, and a fair measure of compensation must of course be paid to officers deprived of private practice. The Association considers that, should circumstances or the public interest oblige officers to give medical attention to private persons, they should retain the fees despite the fact that the right to private practice might have been abolished. There should be no suggestion of "farming out" by Government of a medical officer's services.

12. The Association desires to point out that the remuneration of medically qualified teachers in the medical schools of the Colonial Empire must necessarily be in step with that of Colonial Medical Officers and with that of medical practitioners in the home country if the medical schools are to retain the services of these teachers. There is no need to emphasize the disastrous effects upon the clinical and (not less important) the ethical standard of medical education that would be caused by the loss of medically qualified teachers. This is a danger to which the Association and the Royal Colleges have drawn urgent attention in the United Kingdom.

13. The Association proposes that the new scales of remuneration should have effect from July 5, 1948. This is the date on which the Spens recommendations are deemed to have taken effect in Great Britain.

14. In conclusion, it must be stated that the Association's proposals represent the minimum which can be regarded as comparable with the terms and prospects of medical practitioners at home. No attempt has been made to emulate the maximum of £5,200 recommended in the specialist Spens Report. In drawing up the suggested Standard Scale, the Association has used only average figures recommended for the incomes of general practitioners. The Association's proposals are therefore modest, and it can confidently be asserted that nothing less will be sufficient to attract recruits in competition with the National Health Service.

PROCEEDINGS OF COUNCIL

Wednesday, March 23, 1949

A meeting of the Council of the Association was held at B.M.A. House, London, on Wednesday, March 23. Dr. H. Guy Dain presided.

The Council endorsed a proposal that its Chairman and the Secretary should attend the Commonwealth Medical Conference meeting in association with the annual meeting of the Canadian Medical Association at Saskatoon in June, returning in time for the Harrogate meeting. The President, Sir Lionel Whitby, was unable to attend the Saskatoon meeting, but as he would be in the United States in the autumn a warm invitation had been extended to him to attend any or all of the divisional annual meetings of the Canadian Medical Association to be held in September. The Council expressed its desire that the President should act as ambassador of the Association at as many of these meetings as he could compass, and the President accepted the invitation.

The Association Balance-sheet

Mr. A. M. A. Moore, Treasurer, presented the financial statement for the year ended Dec. 31, 1948. He said that for the first time for 20 years a deficit was shown on the year's income and expenditure. This was largely due to the exceptional expenses incurred by the action which the Association took prior to and after the introduction of the National Health Service. A good deal of this expenditure would be non-recurrent, but the Finance Committee desired to warn the Council of the cost of the new and important services, which

the Association had undertaken. On the assets side the building and other fixed assets had been written down quite generously. Central meetings expenses showed an increase of £6,000; this was due to the additional meetings of the Representative Body and Council and the formation of new committees. Among the general expenses was £3,400 for the Empire Medical Advisory Bureau. The subscription revenue was £145,000, as compared with £138,000 the year before. The membership to-day stood at 60,367—a highly satisfactory state of affairs. The Accountant also told him that the reminders which had to be sent out this year concerning subscriptions unpaid were 600 fewer than a year ago. The *Journal* account again showed a very substantial balance—over £26,000—transferred to the revenue. The financial statement was approved.

Increase in Subscription Rates

Mr. Moore reminded the Council that the Annual Representative Meeting, 1947, expressed the opinion that the time had arrived when an increase in the present subscription rates should be considered. The Finance Committee undertook to consider this matter each year, and it now felt that the time had arrived to recommend an increase. It was 26 years since the subscription of 3 guineas was fixed, and if it was considered how much the Association was doing for its members, how its services had increased during the last year alone, it was evident that a clear case could be made out for a raised subscription. The effect of the proposed increase, if the membership was maintained, would be to increase income by about £34,000.

The recommendations were that the ordinary subscription for members resident in Great Britain and Northern Ireland should be raised to 4 guineas; for newly qualified practitioners elected within two years of registration, 2 guineas; for husband and wife residing together, 5 guineas; for Service members wherever resident, 2½ guineas, and for whole-time non-professional members of teaching staffs of university or medical school and those engaged whole-time on special research, 2½ guineas. There would be no change in the 2 guineas for members of not less than 40 years' standing or members with not less than 10 years' membership who had retired from practice, or in the 1½ guineas for members resident outside Great Britain and Northern Ireland.

After a brief debate the recommendations were unanimously adopted.

Before the Council passed from finance the Chairman mentioned that the former Treasurer, Dr. J. W. Bone, was seriously ill. It had been hoped at a little ceremony to bestow on him the Gold Medal of the Association which had been awarded to him, but he was not well enough for this purpose. His illness would be followed with much sympathy by his many friends in the Association.

Mode of Election of Central Council

Dr. J. A. Pridham, chairman of the Organization Committee, again brought forward his committee's recommendations for a reconstituted Council. At a previous meeting these had been referred back to the committee in order that the details of the proposal might be further elaborated, and this had been done. Dr. Pridham said that the essence of the proposal was that members of Council should be elected from smaller constituencies and by smaller numbers of members. The main alterations affected England, not the rest of the Kingdom. At present 15 members were directly elected from constituencies in England, and it was proposed to raise this number to 29. The number who found their way to the Council by other avenues had accordingly to be cut down. It was proposed that the eight English members elected by grouped representatives should be reduced to four. Reductions were also proposed in the number of members elected by the Representative Body as a whole; and in the number of *ex officio* members.

Dr. O. C. Carter said he did not believe that there was any widespread demand for increased direct representation. It was a demand voiced chiefly by one Division. The election of direct representatives was the form of election in which least interest was taken by the general body of members. He believed that in 75% of the vacancies there was, as a rule, no contest, and that where there was a contest only 25 or 30% of members took the trouble to vote. Indeed, if any change

was to be made it would seem desirable to abolish this direct election altogether and to have the main elections through the Representative Body.

Dr. N. E. Waterfield said that one reason for electoral apathy was that candidates were not known to the constituencies owing to the large areas which the constituencies covered. This would be modified under these proposals. Dr. J. G. Thwaites said that Dr. Carter might argue on the same basis that the Representative Body should be abolished because the meetings to instruct representatives were attended by perhaps only 30% of the electorate. Current criticisms of the Council might be due largely to the fact that members were remote from many of their constituents. With smaller constituencies this would be altered.

Dr. Vaughan Jones and other members asked whether there was any widespread demand for this reform. Dr. R. G. Gordon said that they ought to be sure this was not the demand of a small number of enthusiasts. Dr. I. G. Innes mentioned indications of some widespread demand in Yorkshire and the North. Dr. J. B. Miller considered that the matter was one rather for the Representative Body than for the Council. When the constitution of the Association was last discussed it took five years before the final conclusion was reached, but this fundamental change in the construction of the Council was being hurried through. Dr. S. F. L. Dahne supported the proposals as likely to make the set-up much more democratic.

Dr. Frank Gray moved an amendment that the increase in the number of members directly elected should be approved only provided that adequate arrangements were made to maintain contact between these members and the electorate. A great shout on this subject had come from some Divisions, one of which had given some study to the subject; the others might have done but probably had not. On the other hand, there was a good deal to be said for better contact between members of the Council and the electorate. The Council representative should have the right to be on the executive of each Division in his constituency. Dr. J. A. Ireland said he had assumed that it was the duty of members of Council themselves to keep in touch with their constituency and its organizations. Dr. P. J. Gibbons said that up to now one-third of the Council had been elected by indirect vote, which was a bad method.

The Secretary, in reply to a request for information on the widespread demand, said the experience in the secretariat had been that for several years criticism had quite frequently been expressed that constituencies were too large; this was heard at election time each year. Apart from this there was the Winchester activity and the abundant information demonstrating the interest of other Divisions in the subject which Winchester had collected.

The amendment moved by Dr. Gray was lost, and the Council approved in principle that the number of members directly elected should be increased, so far as the Branches and Divisions in Great Britain and Northern Ireland were concerned, from 22 to 37.

The next recommendation of the committee was that the number of members elected by grouped representatives in the Representative Body be reduced from 12 to 7. Dr. S. Wand said they had to face the question of balanced representation and the necessity of getting knowledgeable people on the Council. For this purpose some method of co-option or some increase in number was necessary. The committee had put forward a geographical method of electing the seven members by grouped representatives, but it involved in one group the inclusion of counties as distant from each other as Lincolnshire and Shropshire, Suffolk and Staffordshire. He thought the geographical method here might well be abandoned, and that there might be one category of members elected by the Representative Body as a whole.

Dr. Pridham replied that the Representative Body seemed to be very much attached to some form of territorial voting, and here four members were provided for England, in roughly geographical areas, one for Wales, and two for Scotland.

Several members spoke in favour of the abandonment of grouped constituency voting in the Representative Body, elections being open to representatives voting as a whole, the manner in which eight seats on the Council have hitherto been filled. It was pointed out that this would give greater opportunity for the election of elder statesmen, whose services it was

desired should be continued, but who might not survive the chances of an election on a geographical pattern.

It was eventually agreed that it be recommended to the Representative Body that voting by representatives of grouped constituencies in the Representative Body should be abolished and that 13 members of Council should be elected by the representatives voting together, with the qualification that two of them should be elected by the Scottish representatives and one by the Welsh. It was further agreed that the immediate past Chairman of the Representative Body, the Deputy Chairman, and the immediate past Treasurer should cease to be members *ex officio*, but that the chairmen of the two new autonomous committees, General Medical Services and Central Consultants and Specialists, should be *ex officio* members. It was pointed out that in these two latter cases it was conceivable that the chairman might not be a member of the Association, but this possibility had existed ever since the Insurance Acts Committee came into being and had given rise to no difficulty. The number of members elected by Overseas Branches was reduced from eight to seven, consequent upon the dissolution of the majority of the Branches in India and Pakistan. The "six-year" rule, whereby a member was prevented from serving for more than six years successively as representative of the same Branch or group, was recommended for abolition on the understanding that there was to be an annual election (except in the case of overseas members, who are elected for three years).

Service Medical Officers

Sir Percy S. Tomlinson said that the Armed Forces Committee had practically completed its review of the rates of pay of Service medical officers in the light of the Spens Reports. It was essential, if the armed Forces were to have efficient medical services, that the terms should be sufficiently attractive to encourage recruitment. He submitted a schedule of revised rates of pay for all ranks in the three Services. Reduced to daily rates for general duty medical officers they involved an increase over the present rate amounting to 3s. in the case of acting surgeon lieutenant R.N., lieutenant, and flying officer; to 15s. in the case of surgeon lieutenant-commander, major, and squadron leader; to 18s. in the case of surgeon commander, lieutenant-colonel, and wing-commander, and 21s. in the case of surgeon captain, colonel, and group-captain.

He added that the committee had been in some difficulty about the remuneration of specialists. It felt that there should be no great gulf between the remuneration of specialists and general duty officers, but that nevertheless specialist pay should be greater than at present, and that the system of payment of specialists, at present varying in the different Services, should be uniform in all three. It was at first thought that a suitable rate would be 6s. a day, but after further reflection it was felt that this rate should apply to graded specialists (junior men), and that 9s. should be the rate for the full specialist.

The Council approved the memorandum and its submission to the Minister of Defence.

The Colonial Medical Service

Sir Hugh Lett introduced a report from the Colonies and Dependencies Committee on the remuneration of officers in the Colonial Medical Service. He said that at the present time the rates of remuneration varied considerably in different Colonies. It was desired to bring the remuneration up to a level comparable with that of general practitioners in this country. The committee wished to work out the remuneration on the basis of the Spens Report, but this gave rise to great difficulties because of the nature of the appointments and the conditions under which these officers worked. But a scale of pensionable remuneration for standard scale and superscale posts, applicable to medical officers serving in all Colonies and Dependencies, had been worked out. The committee had had the advantage of the assistance of officers from Tanganyika, Nigeria, Malaya, and the Falkland Islands. The Colonial Office had agreed to open negotiations on the matter.

He also referred to the recent visit to East Africa of the Assistant Secretary, Dr. E. Grey Turner (*Supplement*, Feb. 12, p. 70). The visit had illustrated the value of contact with the periphery. The Association had 10,000 overseas members, and it was important to consider the desirability of sending out to

the Colonies a representative from either the permanent staff or the Council, not merely when some special question arose, but at regular intervals.

Public Health

Dr. J. Fenton, chairman of the Public Health Committee, said that the policy of refusing local authority advertisements which did not comply with the Association's proposals concerning salaries of whole-time public health medical officers—a policy adopted in view of the delay in setting up Whitley machinery—was now in force. There was reason to believe that some local authorities might attempt to defeat the purpose of the Association by asking general practitioners to undertake the work of assistant medical officers, and part-time women doctors to undertake whole-time duties. He hoped that secretaries of Divisions would be alive to this possibility.

The committee brought forward a recommendation—which was adopted—pressing for the inclusion on the joint committee set up in 1946 to consider the question of equal pay in all its aspects, of representatives from the nursing profession, certain important teaching bodies, and medical auxiliaries. The policy of equal pay for equal work in all professions received the support of the Association on the understanding that any approach by the joint committee to political parties should be strictly non-political and non-selective.

Pay-beds

Mr. A. M. A. Moore brought forward a report from the Consultants and Specialists Committee. He said that the question of the proposed terms and conditions of service for hospital medical staff would be considered at a special meeting of the committee on April 28. One matter which had been before the committee, and was becoming increasingly difficult, was that of pay-beds in hospitals. The committee had strongly recommended to the Joint ("Whitby") Committee that the schedule of fees for operations should be abolished. It raised no objection to the provision in the regulations of an overall inclusive charge for all professional service rendered to a patient in a "ceiling" pay-bed, provided the Minister made a similar restriction on the payment for maintenance.

Doctors' Cars

On the report of the Private Practice Committee the question was again raised of doctors' signs on cars. The committee's recommendation was that no action be taken to encourage the use by members of the Association of a distinctive motor badge. Dr. J. A. Ireland moved the reference back which was seconded by Mr. Lawrence Abel, who said that there was no need for any prominent device, but only for something which would enable the police to give the same priority to the doctor's car as was given in other countries. The motion to refer back was lost and the recommendation approved.

On the amount of security which was necessary for dangerous drugs left in cars, in view of the amended Dangerous Drug Regulations, it was reported that a case was at the moment going to appeal, and further consideration of the matter would best await the judgment. In the meantime, to keep within the law, it appeared necessary to have drugs not merely in a locked car but in a locked receptacle, the car itself not being technically a "receptacle."

Regional Office for Wales

Dr. H. R. Frederick, on behalf of the Welsh Committee, asked the Council to approve in principle of the establishment of a B.M.A. House for Wales, with appropriate staff, to be situated in Cardiff, and that the necessary steps be taken to purchase and equip a suitable building. He said that they looked forward very keenly in Wales to the establishment of this regional office. The office, although it would be in South Wales, would also be much appreciated by North Wales. Steps were being taken in Cardiff to obtain suitable premises. He thanked the Finance Committee for its generosity in taking no exception on financial grounds to the proposal, provided the capital sum for the building and equipment did not exceed £10,000.

Association War Memorial

The Chairman brought forward the report of a committee appointed to consider the question of a memorial to members of the Association who fell in the 1939-45 war. After taking expert advice, the committee proposed that a fountain should be erected in the Court of Honour at B.M.A. House. The cost of the entire memorial on the lines proposed was expected to be in the region of £10,000, and an appeal would be made to members of the Association to meet the cost.

Dr. J. B. W. Rowe urged that, instead of a monument, scholarships be instituted for the education of the children of alien members. Mr. Abel suggested a more ambitious plan of improving the open space at Headquarters. The idea of a fountain, however, was supported by several other members and adopted.

Foreign Corresponding Members

Dr. R. G. Gordon, for the Science Committee, said that no Foreign Corresponding Members had been elected since 1939. At present only five such members were still alive—namely, Professor R. Bastianelli (Italy), Professor Jules Bordet (Belgium), Professor Gosta Forssell (Sweden), Professor G. Marañón (Spain), and Dr. C. F. Regaud (France). It seemed appropriate to elect some additional members to this rank. As many as 45 names had been suggested, but with the help of *Sir Henry Dale* the number had been brought down to 13. He recommended the following for election: Dr. G. Domagk (Germany), Dr. B. A. Houssay (Argentina), Professor E. Proctor (U.S.A.), Professor Einar Key (Sweden), Professor René Leriche (France), Professor Einar Meulengracht (Denmark), Professor Adolf Meyer (U.S.A.), Professor G. R. Minot (U.S.A.), Dr. Emil Novak (U.S.A.), Professor A. N. Richards (U.S.A.), Dr. Peyton Rous (U.S.A.), Dr. Arvid Johan Wallgren (Sweden), and Professor A. O. Whipple (U.S.A.).

The election of those named above was agreed to.

Health Education

The report of the Science Committee contained also a reference to the education of the general public in health matters, following upon the report of a subcommittee which was appointed last autumn. The committee felt strongly that the proper place for health education was the school. The question of a popular health journal was considered and referred to the Journal Committee and the question of films to the Film Committee. In all its considerations the committee had been helped by Dr. Sutherland, secretary of the Central Council or Health Education. A series of recommendations were agreed to. One of them urged Divisions to hold meetings to discuss the promotion of interest in health education. Another discouraged public health propaganda in health centres during the experimental period, and not at all if it was likely to be at the expense of the personal relationship between doctor and patient. Other recommendations favoured the encouragement of members of the profession to interest themselves in the education of children in health matters.

International Relations

A recommendation of the International Relations Committee, presented by Dr. Fridham, aroused some discussion. In view of inaccurate American reports of British experience of the National Health Service, the Council was asked to express the opinion that British doctors who made statements on the service to the American profession or press should be careful to emphasize that they were giving their personal views only. Lord Horder said he would agree that no one of them knew enough about the workings of the N.H.S. to express any other opinion than his own. There had been representations made in America from the Association as to the position of the N.H.S. in this country, and he did not remember that the recommendation on the subject carried with it the caution expressed here. Mr. Abel suggested that some factual official document could be got out which could be used by those who had to speak to audiences abroad or had contacts with the foreign press.

The Secretary said that there was a tendency in some quarters in America consistently to misrepresent the position in this country. He referred as an example to a statement in the

Journal of the American Medical Association that general practitioners in this country were writing out their prescriptions and orders for treatment before actually seeing their patients. This sort of thing was not new: it went back to N.H.I. days. Those who spoke or wrote on the subject should be on their guard lest unwittingly they confirmed a false impression.

The recommendation was adopted.

Other Committees

The revised duties and ethical rules of industrial medical officers, brought forward by the Occupational Health Committee, were approved.

The Chairman of Council introduced a report on the N.H.S. Amending Bill. The amendments proposed will be found set out in the Annual Report of Council.

On the recommendation of the Central Ethical Committee it was agreed to request the World Medical Organization to afford its member bodies an opportunity of discussing and commenting upon the proposed draft oath prepared by the Assembly with the suggested title "Declaration of Geneva."

Dr. O. C. Carter presented a report of the Journal Committee with recommendations to facilitate more rapid printing of the *Journal*.

Mr. Dougal Callander brought forward a report of the Building Committee concerning various improvements and amenities at B.M.A. House.

Other routine or progress reports were submitted on behalf of the General Medical Services Committee (including a recommendation to raise the number of directly elected members from 27 to 33), the Scottish Committee, the Joint Committee on Psychiatry and the Law, the Ophthalmic Group Committee, the Public Relations Committee, and the Film Committee.

Dr. J. Fenton and Dr. H. H. D. Sutherland were appointed delegates to attend the Annual Conference on Maternity and Child Welfare, to be held in London in June. With regard to the Canterbury Commemoration of the science and art of healing, on June 25, the date conflicting with the Annual General Meeting, it was left to the Chairman of Council and the Chairman of the Representative Body to enrol the expected B.M.A. representation.

The final act of the Council was to approve the draft Annual Report, which appears in the *Supplement* at p. 174.

SPECIAL REPRESENTATIVE MEETING

DECISIONS ON GENERAL PRACTITIONER REMUNERATION

A Special Representative Meeting, called on the requisition of the Council, was held in the Great Hall of B.M.A. House, London, on March 29. Its business was to consider the question of remuneration to general practitioners under the National Health Service Acts.

The chair was taken by Dr. E. A. Gregg, Chairman of the Representative Body, who was supported by Dr. H. Guy Dain, Chairman of Council, Dr. S. Wand, Chairman of the General Medical Services Committee, Mr. A. M. A. Moore, Treasurer, and Dr. Charles Hill, Secretary.

Dr. Dain said that the General Medical Services Committee, which represented general practitioners, was an autonomous body, with power to go to the Minister, but it was also a standing committee of the Association. The report of the committee on remuneration had been approved by the recent Conference, and the purpose of the present meeting was to show that the full weight of the Association was behind the case for the general practitioner.

Report of General Medical Services Committee

The principal document before the meeting was the report on the remuneration of general practitioners (*Supplement*, Feb. 19, p. 83), which had been accepted without amendment by the Conference of Local Medical Committees (*Supplement*, March 12, p. 129).

Dr. Wand moved:

That the fullest support be given to the Conference of Local Medical Committees in seeking an adjustment of general practitioner remuneration on the basis of the report prepared by the General Medical Services Committee.

Dr. Wand said that there had been a great deal of dissatisfaction among general practitioners about remuneration. In the Association they were always anxious to have a properly documented case before they took action. Inquiry had been made by the Association in certain survey areas into the income of practitioners, and it was found that, although Spens was implemented for those in the 40-49 age group—on the assumption of a betterment of 20%—yet over the whole range there were groups which were not receiving what Spens said they ought to receive—in other words, there was maldistribution.

Three points were wrong: (1) The betterment bore an inadequate relationship to the present-day value of money; (2) while Spens was based on 17,900 in the Service, the figure was two or three thousand higher than that; (3) there were errors in distribution. In this Service so far the profession had done a proper job of work. Neither the public nor the Minister could complain that they had failed in their part of the bargain. Under harassing conditions and for unreasonable hours they had carried out their contract. Had practitioners not been willing to put up with exceptional conditions and strain the Service would have broken down. Had the Government carried out its part of the contract? Spens stated that the value of money must be brought up to present-day values. But what had happened? For 20s. in 1938 practitioners were now receiving only 24s. Did that adequately represent the altered money values? The altered value of money was represented by a figure of 185 as compared with 100 pre-war. But it was not felt to be reasonable to ask for 185 when other comparable sections of the community were not getting that full amount. Therefore it was recommended that a betterment factor of 170 should be attached to the 1938 values. It was also the view of the committee that, having regard to the difficulties of the lower- and middle-income groups, the fairest method would be to attach any new moneys to the first thousand on the practitioner's list.

Dr. A. Fyfe (Oldham) moved an amendment to Part I of the Report which concerned the adequacy of the Central Pool:

That this meeting is of opinion that practitioners should receive an actual payment of 30s. per head for each patient on their lists and that payment be retrospective to July 5, 1948.

There was no fairness in a scheme of payment which resulted in the present wide variations, and such discrepancies could only be got over by a fixed capitation fee. Oldham realized that its suggestion would mean a departure from the Spens recommendations, but as Dr. Cockshut had said in a letter to the *Journal* on Jan. 8, "If Spens gives us poor remuneration, then away with Spens."

Dr. Wand said that Oldham's suggestion would cost between £26 million and £27 million. The committee had attached itself to the pool method.

The Oldham amendment was lost by an overwhelming majority.

Maximum Number on Lists

Dr. Stevens (Huddersfield) moved a reduction to 3,000 instead of 4,000 as the maximum number of patients allowable under one doctor. His Division felt that 3,000 was as many as a doctor could manage adequately and efficiently.

Dr. Howie Wood (Isle of Wight) said that 3,000 should be the maximum number which a practitioner single-handed should be expected or allowed to look after. There were exceptional cases, but the average had to be considered.

Dr. J. C. Arthur (Gateshead) was surprised at "the outbreak of trade unionism and restrictive practices in the Isle of Wight." If the bricklayers did what the doctors proposed to do we should not get many houses. By passing this amendment we should be penalizing the most efficient and hardworking doctors and depriving patients of free choice.

Dr. R. W. Cockshut (Hendon) asked who were they to say to a patient who preferred one four-thousandth part of a doctor's time rather than one two-thousandth part that he should not have it? To adopt 3,000 would be dangerously near putting them all on the same level—all having the same number of patients.

Dr. W. Jope (Glasgow) said that the population of Great Britain was approximately 48 millions. There were 20,000 general practitioners available. When the number of general practitioners was increased it might be possible substantially to reduce the number on doctors' lists. Making allowance

for sparsely populated areas and other factors, young and active practitioners must be expected to look after a larger number than 3,000.

Dr. W. N. Leak (Cheshire) said that this was much too early in the Service for such an element of compulsion to be introduced.

The Huddersfield amendment was lost by a large majority.

Dr. H. H. Goodman (Newcastle) moved that the ceiling limit on doctors' lists should be reduced in accordance with the amount of extra money which the Minister agreed to add to the pool. This was the only opportunity they would have of broaching this particular subject, which must come up ultimately, without causing a split in the profession. This would solve the problem of the redistribution of doctors.

Dr. Wand said they were now making an application for a betterment increase dated back to July 5. An inquiry into the amount of work of the general practitioner was now taking place. This matter of size of lists was not bound up with betterment but with extra work. The Newcastle rider would be an obstacle which would cause embarrassment at a time when they were not discussing this particular problem at all.

The Newcastle rider was lost by an overwhelming majority.

Dr. W. J. Poole (Ashton-under-Lyne) moved that an approach be made to the Minister with a view to securing an immediate interim rise in the capitation fee in order to relieve the widespread financial distress existing throughout the profession, and that the Council be empowered to decide upon an adequate increase in the light of the knowledge now available. There were only two courses of action open to them: either to go all out for a high figure, or, in the terms of this amendment, to approach the Minister with a reasonable demand for a rise in pay to relieve the obvious distress which was afflicting a great number of practitioners. This distress was very real. There were only two sorts of general practitioners to-day: those who were trying to do too much and those for whom general practice was practically no longer an economic proposition.

Dr. J. A. Ireland (Council) said that no useful purpose would be served by this amendment. The point was amply covered by the report of the committee.

Dr. Dain said the fact that Ashton-under-Lyne should turn up with this amendment filled him with amazement. One of the first Divisions to protest against the inadequate capitation fee was Ashton-under-Lyne, but when the figures were investigated it was found that the incomes of practitioners there were not too bad. They now came up and asked that the figures which had been prepared in support of the practitioners' case should be scrapped and that they should go to the Minister without any argument whatever and see whether he would be kind enough to give them a little more of the money which he had to spare. Anything more defeatist he could not imagine.

Dr. Poole said it was clearly stated in the Ashton-under-Lyne amendment that they were seeking an interim rise pending the adoption of a final figure. He indignantly denied that his Division was defeatist.

The Ashton-under-Lyne amendment was lost.

The Betterment Factor

Amendments calling for a betterment factor of 185 were on the paper in the name of Bishop Auckland; Hampstead, Harrow, Paddington, Halifax, Folkestone and Dover, Brighton, and Finchley Divisions. Dr. F. Lishman (Bishop Auckland) said that his Division could not understand why a betterment factor of 170 should be asked for when the extra figure for 1948 was 185. Dr. J. Kennedy (Hampstead) said that no case had been made out for not accepting the advice of the expert economist who had investigated the question of betterment and had arrived at the figure of 185. The profession had had a raw deal. Dr. J. B. W. Rowe (Harrow) supported 185. The Harrow Division considered that it was time they got really tough and asked for what they deserved. Dr. G. de Swiet (Paddington) said that the publication of the terms for specialists had made general practitioners' remuneration, unless they got this enhanced betterment, "look like chicken-feed." Dr. D. L. S. Johnston (Halifax) considered that the recent Conference was weak in not pressing for 185. It suggested that they did not trust their own figures. Moreover, what was 185 a year ago might be 225 to-day. Dr. Fletcher

(Finchley) considered the policy of the Council to be one of expediency rather than what was best for the profession.

Dr. R. W. Cockshut (Hendon): The heavy expense ratio they were able to show when the Spens estimate was calculated included locumtenents and assistants. There had been a fall in drug expenses. Did they think that an investigation into their total income to-day would show that out of £134 received they had to spend £62 in expenses to get it?

Dr. Frank Gray (Council): If they got 185 they would be tied to that figure. The sellers' market was changing to a buyers' market. There was a likelihood that prices would fall. If they were tied to 185 it meant automatically that on such a fall the capitation fee must be reduced. If they did not go out for the full figure they would have a margin or buffer, and it would not be possible for the Government to call for an immediate decrease on a fall in the cost of living. Dr. H. H. Goodman: We should ask our negotiators to stand by 170, a figure which we could really substantiate.

Dr. Wand hoped the meeting would not instruct its negotiators on a figure which was vulnerable. The figure of 170 applied to the whole income was fair and reasonable.

The amendment to press for a betterment factor of 185 was lost by a large majority.

In speaking in opposition to a Gloucestershire amendment, which, he said, embodied a threat of resignation if 170 were not obtained, Dr. Wand said that at this time there was no mandate on that issue. He had promised that they should go back to local medical committees with the results of their conversations with the Ministry. This was an inappropriate moment to pass binding resolutions. There would be another opportunity to discuss these matters.

It was agreed to pass to the next business. The same course was taken with an amendment in the name of Barrow-in-Furness.

Dr. J. Ewart Purves (Bromley) moved approval of the Council's recommendation without prejudice to such adjustments as might be suggested by a further investigation of the application of the Spens recommendations in the southern half of England. An investigation in the county of Kent had shown that, although Spens was being implemented over the higher range of salaries, in the lower ranges it was not being implemented. He did not think that Lancashire multiplied by 20 was representative of the whole country.

The amendment was referred to the committee.

Dr. P. A. McCallum (Torquay) moved: "That the best argument for extra pay is that we are doing extra work."

Dr. J. A. Brown (Birmingham): There were many better arguments to put to the Minister than this. The first was that they had never been properly paid for any work they had done. There was never a time when the best men in general practice were more needed. The opportunities to-day in general practice were far greater than in specialism. It would be deplorable if the attractions of specialism robbed general practice of men of the calibre who formerly went in for it. To say that the best argument was that more work was being done was sheer nonsense.

Dr. Wand: It is our intention to investigate the burden of work at a later date.

The Torquay amendment was decisively negatived.

Distribution of Revised Pool

The meeting then turned to Part II of the report, on which Sheffield moved an amendment urging that not until it was known what additional funds the profession was going to receive from the Ministry should the distribution of this money be decided, and whatever decision was made should be open to review in two years' time.

Dr. Wand: Sheffield seemed to think there was some other method of doing it than the one the committee suggested. On balance the attachment of the extra money to the first 1,000 was the most effective in serving the purpose they had in view and administratively the most easy to carry out.

The Sheffield amendment was lost.

A Uniform Fee

Harrow, Coventry, and Hartlepool had amendments calling for a uniform capitation fee, with no loading of particular groups.

In reply to various arguments Dr. Wand said that an equal increase over the whole range of lists would mean a complete distortion of the Spens recommendations without any relief to hardship cases.

Dr. W. Jope (Glasgow) and others continued the debate, after which an amendment for a uniform capitation fee with no loading was lost.

The First 2,000

Dr. A. Brown (Cambridge and Huntingdon) moved that if the increase in the total pool is under £10 million it should be utilized for the first 1,000 on the individual doctor's list; if over that amount, then for the first 2,000.

Mr. Staveley Gough (Council) thought it reasonable that the increase should be distributed over a larger group.

Dr. Wand: If this extra money were attached to the first 2,000 it would be so watered down that the help it was desired to give would not be forthcoming.

Dr. Dain: Everyone in practice had certain fundamental expenses that could not be escaped, whatever his income, and it was not unreasonable that people with small lists should have a larger sum of money because they would have to meet expenses very nearly as large as those with the larger lists.

The Cambridge and Huntingdon amendment was lost, and this completed the matters arising on Parts I and II of the report. The motion proposed by Dr. Wand at the beginning, calling for the fullest support to be given to the Conference of Local Medical Committees in seeking an adjustment of general practitioner remuneration on the basis of its proposals, was put to the meeting and carried apparently unanimously.

The Chairman of Council, in moving a rider to the resolution, said he thought that the meeting should express disapproval of the delay by the Ministry in implementing the profession's requirements, and he therefore moved:

"That the Representative Body expresses its great concern that the Minister, having received the general practitioners' representations on the betterment factor more than two months ago and the case set out in M.22 on March 4, has not conceded the necessary adjustments to the pool to implement Spens at present-day values in time for the increased payments to be made in this quarter's payments. This delay shows disregard for the serious hardship now being experienced by many general practitioners in the Service and is seriously prejudicing its success."

He said if the claim had been dealt with at the beginning of this month it would have been possible to receive in the cheques they were to get at the end of the week the increased payment. The delay had rendered this impossible.

The motion was carried unanimously.

Dr. F. M. Rose (Preston) had a motion expressing anxiety at the serious financial position created by the N.H.S. for many general practitioners, and supporting the efforts of the committee to obtain an adequate betterment factor. This was carried.

Dr. D. A. Robertson (Reigate) asked that it be made clear that the profession was at present obtaining a 120 betterment factor applied to income and 155 factor applied to expenses, and that what was now being asked for was a factor of no more than 135 applied to income only as between the years 1938 and 1948. The Public Relations Department should see that these figures were emphasized in any statements issued to the Press.

Dr. Wand pointed out that there was an inaccuracy in the figures, and he suggested that Reigate would be satisfied if the Representative Body noted the point and left it at that.

Dr. Robertson agreed and with permission withdrew the motion.

Dr. J. C. Arthur (Gateshead), while accepting the proposed loading for the first 1,000 as the simplest method of meeting present conditions, moved to reaffirm the conviction that remuneration should be related to amount of work done and responsibilities undertaken, and this was carried.

Dr. Agnes S. Nutt (Sheffield) drew attention to the fact that the sum now available in the Sheffield area for distribution through the Local Executive Council represents a sum of 17s. 0½d., instead of the anticipated 17s. 5d., and asked that the matter be pressed on the Minister with a view to its rectification. This was referred to the General Medical Services Committee.

Dr. Wand said that there had been a great deal of dissatisfaction among general practitioners about remuneration. In the Association they were always anxious to have a properly documented case before they took action. Inquiry had been made by the Association in certain survey areas into the income of practitioners, and it was found that, although Spens was implemented for those in the 40-49 age group—on the assumption of a betterment of 20%—yet over the whole range there were groups which were not receiving what Spens said they ought to receive—in other words, there was maldistribution.

Three points were wrong: (1) The betterment bore an inadequate relationship to the present-day value of money; (2) while Spens was based on 17,900 in the Service, the figure was two or three thousand higher than that; (3) there were errors in distribution. In this Service so far the profession had done a proper job of work. Neither the public nor the Minister could complain that they had failed in their part of the bargain. Under harassing conditions and for unreasonable hours they had carried out their contract. Had practitioners not been willing to put up with exceptional conditions and strain the Service would have broken down. Had the Government carried out its part of the contract? Spens stated that the value of money must be brought up to present-day values. But what had happened? For 20s. in 1938 practitioners were now receiving only 24s. Did that adequately represent the altered money values? The altered value of money was represented by a figure of 185 as compared with 100 pre-war. But it was not felt to be reasonable to ask for 185 when other comparable sections of the community were not getting that full amount. Therefore it was recommended that a betterment factor of 170 should be attached to the 1938 values. It was also the view of the committee that, having regard to the difficulties of the lower- and middle-income groups, the fairest method would be to attach any new moneys to the first thousand on the practitioner's list.

Dr. A. Fyfe (Oldham) moved an amendment to Part I of the Report which concerned the adequacy of the Central Pool:

That this meeting is of opinion that practitioners should receive an actual payment of 30s. per head for each patient on their lists and that payment be retrospective to July 5, 1948.

There was no fairness in a scheme of payment which resulted in the present wide variations, and such discrepancies could only be got over by a fixed capitation fee. Oldham realized that its suggestion would mean a departure from the Spens recommendations, but as Dr. Cockshut had said in a letter to the *Journal* on Jan. 8, "If Spens gives us poor remuneration, then away with Spens."

Dr. Wand said that Oldham's suggestion would cost between £26 million and £27 million. The committee had attached itself to the pool method.

The Oldham amendment was lost by an overwhelming majority.

Maximum Number on Lists

Dr. Stevens (Huddersfield) moved a reduction to 3,000 instead of 4,000 as the maximum number of patients allowable under one doctor. His Division felt that 3,000 was as many as a doctor could manage adequately and efficiently.

Dr. Howie Wood (Isle of Wight) said that 3,000 should be the maximum number which a practitioner single-handed should be expected or allowed to look after. There were exceptional cases, but the average had to be considered.

Dr. J. C. Arthur (Gateshead) was surprised at "the outbreak of trade unionism and restrictive practices in the Isle of Wight." If the bricklayers did what the doctors proposed to do we should not get many houses. By passing this amendment we should be penalizing the most efficient and hardworking doctors and depriving patients of free choice.

Dr. R. W. Cockshut (Hendon) asked who were they to say to a patient who preferred one four-thousandth part of a doctor's time rather than one two-thousandth part that he should not have it? To adopt 3,000 would be dangerously near putting them all on the same level—all having the same number of patients.

Dr. W. Jope (Glasgow) said that the population of Great Britain was approximately 48 millions. There were 20,000 general practitioners available. When the number of general practitioners was increased it might be possible substantially to reduce the number on doctors' lists. Making allowance

for sparsely populated areas and other factors, young and active practitioners must be expected to look after a larger number than 3,000.

Dr. W. N. Leak (Cheshire) said that this was much too easy in the Service for such an element of compulsion to be introduced.

The Huddersfield amendment was lost by a large majority.

Dr. H. H. Goodman (Newcastle) moved that the ceiling limit on doctors' lists should be reduced in accordance with the amount of extra money which the Minister agreed to add to the pool. This was the only opportunity they would have of broaching this particular subject, which must come up ultimately, without causing a split in the profession. This would solve the problem of the redistribution of doctors.

Dr. Wand said they were now making an application for a betterment increase dated back to July 5. An inquiry into the amount of work of the general practitioner was now taking place. This matter of size of lists was not bound up with betterment but with extra work. The Newcastle rider would be an obstacle which would cause embarrassment at a time when they were not discussing this particular problem at all.

The Newcastle rider was lost by an overwhelming majority.

Dr. W. J. Poole (Ashton-under-Lyne) moved that an approach be made to the Minister with a view to securing an immediate interim rise in the capitation fee in order to relieve the widespread financial distress existing throughout the profession, and that the Council be empowered to decide upon an adequate increase in the light of the knowledge now available. There were only two courses of action open to them: either to go all out for a high figure, or, in the terms of this amendment, to approach the Minister with a reasonable demand for a rise in pay to relieve the obvious distress which was afflicting a great number of practitioners. This distress was very real. There were only two sorts of general practitioners to-day: those who were trying to do too much and those for whom general practice was practically no longer an economic proposition.

Dr. J. A. Ireland (Council) said that no useful purpose would be served by this amendment. The point was amply covered by the report of the committee.

Dr. Dain said the fact that Ashton-under-Lyne should turn up with this amendment filled him with amazement. One of the first Divisions to protest against the inadequate capitation fee was Ashton-under-Lyne, but when the figures were investigated it was found that the incomes of practitioners there were not too bad. Anything more defeatist he could not imagine.

Dr. Poole said it was clearly stated in the Ashton-under-Lyne amendment that they were seeking an interim rise pending the adoption of a final figure. He indignantly denied that his Division was defeatist.

The Ashton-under-Lyne amendment was lost.

The Betterment Factor

Amendments calling for a betterment factor of 185 were on the paper in the name of Bishop Auckland; Hampstead, Harrow, Paddington, Halifax, Folkestone and Dover, Brighton, and Finchley Divisions. Dr. F. Lishman (Bishop Auckland) said that his Division could not understand why a betterment factor of 170 should be asked for when the extra figure for 1948 was 185. Dr. J. Kennedy (Hampstead) said that no case had been made out for not accepting the advice of the expert economist who had investigated the question of betterment and had arrived at the figure of 185. The profession had had a raw deal. Dr. J. B. W. Rowe (Harrow) supported 185. The Harrow Division considered that it was time they got really tough and asked for what they deserved. Dr. G. de Swiet (Paddington) said that the publication of the terms for specialists had made general practitioners' remuneration, unless they got this enhanced betterment, "look like chicken-feed." Dr. D. L. S. Johnston (Halifax) considered that the recent Conference was weak in not pressing for 185. It suggested that they did not trust their own figures. Moreover, what was 185 a year ago might be 225 to-day. Dr. Fletcher

(Finchley) considered the policy of the Council to be one of expediency rather than what was best for the profession.

Dr. R. W. Cockshut (Hendon): The heavy expense ratio they were able to show when the Spens estimate was calculated included locumtenents and assistants. There had been a fall in drug expenses. Did they think that an investigation into their total income to-day would show that out of £134 received they had to spend £62 in expenses to get it?

Dr. Frank Gray (Council): If they got 185 they would be tied to that figure. The sellers' market was changing to a buyers' market. There was a likelihood that prices would fall. If they were tied to 185 it meant automatically that on such a fall the capitation fee must be reduced. If they did not go out for the full figure they would have a margin or buffer, and it would not be possible for the Government to call for an immediate decrease on a fall in the cost of living. Dr. H. H. Goodman: We should ask our negotiators to stand by 170, a figure which we could really substantiate.

Dr. Wand hoped the meeting would not instruct its negotiators on a figure which was vulnerable. The figure of 170 applied to the whole income was fair and reasonable.

The amendment to press for a betterment factor of 185 was lost by a large majority.

In speaking in opposition to a Gloucestershire amendment, which, he said, embodied a threat of resignation if 170 were not obtained, Dr. Wand said that at this time there was no mandate on that issue. He had promised that they should go back to local medical committees with the results of their conversations with the Ministry. This was an inappropriate moment to pass binding resolutions. There would be another opportunity to discuss these matters.

It was agreed to pass to the next business. The same course was taken with an amendment in the name of Barrow-in-Furness.

Dr. J. Ewart Purves (Bromley) moved approval of the Council's recommendation without prejudice to such adjustments as might be suggested by a further investigation of the application of the Spens recommendations in the southern half of England. An investigation in the county of Kent had shown that, although Spens was being implemented over the higher range of salaries, in the lower ranges it was not being implemented. He did not think that Lancashire multiplied by 20 was representative of the whole country.

The amendment was referred to the committee.

Dr. P. A. McCallum (Torquay) moved: "That the best argument for extra pay is that we are doing extra work."

Dr. J. A. Brown (Birmingham): There were many better arguments to put to the Minister than this. The first was that they had never been properly paid for any work they had done. There was never a time when the best men in general practice were more needed. The opportunities to-day in general practice were far greater than in specialism. It would be deplorable if the attractions of specialism robbed general practice of men of the calibre who formerly went in for it. To say that the best argument was that more work was being done was sheer nonsense.

Dr. Wand: It is our intention to investigate the burden of work at a later date.

The Torquay amendment was decisively negatived.

Distribution of Revised Pool

The meeting then turned to Part II of the report, on which Sheffield moved an amendment urging that not until it was known what additional funds the profession was going to receive from the Ministry should the distribution of this money be decided, and whatever decision was made should be open to review in two years' time.

Dr. Wand: Sheffield seemed to think there was some other method of doing it than the one the committee suggested. On balance the attachment of the extra money to the first 1,000 was the most effective in serving the purpose they had in view and administratively the most easy to carry out.

The Sheffield amendment was lost.

A Uniform Fee

Harrow, Coventry, and Hartlepool had amendments calling for a uniform capitation fee, with no loading of particular groups.

In reply to various arguments Dr. Wand said that an equal increase over the whole range of lists would mean a complete distortion of the Spens recommendations without any relief to hardship cases.

Dr. W. Jope (Glasgow) and others continued the debate, after which an amendment for a uniform capitation fee with no loading was lost.

The First 2,000

Dr. A. Brown (Cambridge and Huntingdon) moved that if the increase in the total pool is under £10 million it should be utilized for the first 1,000 on the individual doctor's list; if over that amount, then for the first 2,000.

Mr. Staveley Gough (Council) thought it reasonable that the increase should be distributed over a larger group.

Dr. Wand: If this extra money were attached to the first 2,000 it would be so watered down that the help it was desired to give would not be forthcoming.

Dr. Dain: Everyone in practice had certain fundamental expenses that could not be escaped, whatever his income, and it was not unreasonable that people with small lists should have a larger sum of money because they would have to meet expenses very nearly as large as those with the larger lists.

The Cambridge and Huntingdon amendment was lost, and this completed the matters arising on Parts I and II of the report. The motion proposed by Dr. Wand at the beginning, calling for the fullest support to be given to the Conference of Local Medical Committees in seeking an adjustment of general practitioner remuneration on the basis of its proposals, was put to the meeting and carried apparently unanimously.

The Chairman of Council, in moving a rider to the resolution, said he thought that the meeting should express disapproval of the delay by the Ministry in implementing the profession's requirements, and he therefore moved:

"That the Representative Body expresses its great concern that the Minister, having received the general practitioners' representations on the betterment factor more than two months ago and the case set out in M.22 on March 4, has not conceded the necessary adjustments to the pool to implement Spens at present-day values in time for the increased payments to be made in this quarter's payments. This delay shows disregard for the serious hardship now being experienced by many general practitioners in the Service and is seriously prejudicing its success."

He said if the claim had been dealt with at the beginning of this month it would have been possible to receive in the cheques they were to get at the end of the week the increased payment. The delay had rendered this impossible.

The motion was carried unanimously.

Dr. F. M. Rose (Preston) had a motion expressing anxiety at the serious financial position created by the N.H.S. for many general practitioners, and supporting the efforts of the committee to obtain an adequate betterment factor. This was carried.

Dr. D. A. Robertson (Reigate) asked that it be made clear that the profession was at present obtaining a 120 betterment factor applied to income and 155 factor applied to expenses, and that what was now being asked for was a factor of no more than 135 applied to income only as between the years 1938 and 1948. The Public Relations Department should see that these figures were emphasized in any statements issued to the Press.

Dr. Wand pointed out that there was an inaccuracy in the figures, and he suggested that Reigate would be satisfied if the Representative Body noted the point and left it at that.

Dr. Robertson agreed and with permission withdrew the motion.

Dr. J. C. Arthur (Gateshead), while accepting the proposed loading for the first 1,000 as the simplest method of meeting present conditions, moved to reaffirm the conviction that remuneration should be related to amount of work done and responsibilities undertaken, and this was carried.

Dr. Agnes S. Nutt (Sheffield) drew attention to the fact that the sum now available in the Sheffield area for distribution through the Local Executive Council represents a sum of 17s. 0½d., instead of the anticipated 17s. 5d., and asked that the matter be pressed on the Minister with a view to its rectification. This was referred to the General Medical Services Committee.

Dr. A. B. Robinson (Buckinghamshire) called upon the meeting to instruct the Council to advise mass resignation of general practitioners from the Service if an adequate capitation fee is not obtained by an early date.

Dr. Wand said that this was not the meeting at which a decision of this kind would normally be made. There could be no complaint that doctors had acted in a hurried manner; they had felt frustration for the whole period of the Service in the financial sense. They had now put up a reasonable case, and it was hoped it would be met in a reasonable way. If it was not, further action would have to be decided upon at that stage. At this moment it was hoped that in the interests of this great Service the Minister would see the importance of meeting the profession in the way indicated.

It was moved from several parts of the meeting to pass to the next business, and this was agreed to.

Mileage

Dr. G. H. Edgecombe (Westmorland) moved that a much larger sum than £2 million should be set aside for mileage payments in view of the special difficulties of rural practitioners. He said that the average size of list was 1,400 patients, and the doctors with small lists found their work hard and time-consuming. The income therefrom was not such as made a living possible. The mileage grant covered only the cost of cars, and in these hard districts deterioration was rapid.

Dr. F. M. Rose (Preston), whose Branch had a similar motion on the agenda, said that the matter should go back again to the General Medical Services Committee for further consideration.

Dr. J. C. Pearce (chairman, Rural Practitioners Subcommittee) said that the fund had not been entirely distributed, the matter was still under consideration, and when a scheme had been drawn up it was hoped to have a meeting with the Minister to discuss it, particularly from the point of view of the difficult areas.

Dr. Wand said that it might prove that the new mileage sums would be adequate; the whole of the increase was being attached to the first 1,000 patients, which meant a substantial addition to the income of the rural practitioner.

After Dr. Edgecombe had made a brief reply the motion was carried.

A motion by Reading called attention to special difficulties in Berkshire, and Dr. Wand said that there was evidently some local hitch which would be investigated.

Dr. M. E. P. Kitlard-Leavey (Barnstaple) considered that areas with geographical difficulties, such as existed in North Devon, should be given greater payment for mileage. Dr. Wand said that this was in process of being dealt with.

Dr. R. Rose (Reading) called upon the meeting to press for the inclusion of a mileage grant within the framework of the maternity service. Dr. W. N. Leak supported this, and Dr. H. B. Muir complained of conditions respecting mileage in Scotland.

Dr. Wand said that they had got half a million from the Ministry for mileage. This included mileage for maternity cases. He hoped they would not start asking for little bits here and there. They should be realists in this matter. An increase of 200% was not unreasonable for a trial period such as they were going through. Dr. G. P. Williams (Caernarvon), Dr. Fletcher (Cumberland), Dr. R. H. McColl (Denbigh and Flint), and Dr. Hughes (South-west Wales) gave their own experience of mileage allowance inadequacy.

Dr. Wand: They were getting figures quoted on this mileage problem that afternoon which were so different from those used at the Ministry by an experienced rural practitioner that he wanted some further facts.

Dr. J. C. Pearce (chairman of Rural Practitioners Subcommittee) said he could only wish that speakers who had presented their difficulties that afternoon had let his subcommittee know about them when they were collecting information. There were so many conditions that it was impossible even for rural practitioners in other parts of the country to be able to deal with them all.

Dr. Rose (Reading), in reply, was grateful to his rural practitioner colleagues for relating their experiences. One further fact: practically 100% of "truly rural" practitioners had lost precisely 100% of their private cases.

It was agreed that the motion should be referred to the General Medical Services Committee.

Dr. L. R. Routledge (Hexham) urged a material increase in the rural practitioner's dispensing allowance.

Dr. J. A. Pridham (Council) and Dr. J. R. Baker (Scunthorpe) contributed to the discussion, and the matter was referred to the committee.

Denbigh and Flint had a motion that in the case of partnerships the total number of capitation units in the practice should be distributed among the partners in their appropriate share, irrespective of the numbers on their individual lists, and the "loading" of the first thousand in each case to be in accordance with the amount available under betterment.

Dr. Wand: In the case of a partnership there would be a "loading" of the first thousand in respect of each partner, provided there were enough patients in the partnership to go round. A partnership of 2,000, however distributed between the two partners, would carry two loadings.

The Denbigh and Flint motion was declared by the Chairman carried.

Superannuation

Dr. Scott Webb (Woolwich) moved that the pension and other superannuation rights of practitioners should be calculated on income averaged over the three or five years of maximum income, as is, in effect, the case with almost all persons participating in statutory superannuation schemes. The calculation of the pension and other superannuation benefits on income averaged over all the years of service was most prejudicial.

Dr. Wand: They were satisfied, as a result of advice given by their actuary, that the funds received or about to be received by the profession for superannuation were a very fair return for the money paid in; but this matter of years of maximum earnings was fully discussed, and the matter had been taken care of by the increase from 1½ to 1¾%.

Dr. Scott Webb expressed himself still dissatisfied.

The Secretary (Dr. Hill) said that the objection on the Government side to this "maximum earnings" basis was that a practitioner might indulge in unusual efforts for the three or five years selected for the purpose of calculation. The basis adopted was, they were assured by the actuary, no less satisfactory than the method adopted in the case of the whole-time officer.

The Woolwich motion was lost.

A motion by Trowbridge asked that attention be drawn to the fact that regional boards, in making payments to general-practitioner specialists, were not empowered to allot superannuation benefits in proportion to partnership shares in the case of practitioners in partnership in the same way as executive councils were empowered—a situation which caused great difficulties in certain partnerships. It was agreed to refer this matter to the committee.

Mr. J. G. R. Murray (Exeter) asked for adequate payment for the treatment of temporary residents from the central fund.

Dr. Howie Wood (Isle of Wight) asked for an assurance that moneys would be forthcoming from the central fund which would give a just and proper fee for those areas where temporary residents were treated.

Dr. Wand: For the first two quarters of the Service a sum was being deducted from central funds equal to 8s. for temporary residents. The whole problem was being investigated before a permanent scheme was agreed.

The motion was referred to the committee.

Holidays: Study Leave

Dr. P. H. Rosedale (Marylebone) moved that it would be beneficial for regular arrangements to be made for holidays with pay and periodical study leave.

Dr. J. A. Brown said that if it was the intention to ask the Government to make the arrangements it would be a step towards a whole-time service.

Dr. Howie Wood (Isle of Wight) and Dr. D. E. Yarrow (Tunbridge Wells) spoke in support of the motion and Dr. A. Beauchamp against. Dr. Wand deprecated this and similar motions in the name of other Divisions. What the committee was asking for was an adequate pool.

The Marylebone motion was lost, and other motions on the subject were withdrawn.

Monthly Payments Requested

Dr. Stevens (Huddersfield) asked for capitation fees to be payable monthly instead of quarterly.

Dr. Wand: If this was passed it might be sympathetically considered by the Ministry. But there were certain possible disadvantages in respect of dates on which taxation payments became due. The motion that capitation fees be paid monthly was lost by 66 to 78.

Autonomy of Sectional Committees

Dr. P. A. McCallum (Torquay) drew attention to the need for carefully considering and if possible correlating the points of view of the committees concerned respectively with general practitioners and with specialists and the public health group. While agreeing that the greatest possible autonomy should be accorded to each section, any decisions of such committees affecting the policy of the Association should not be announced to the public and the Ministry until finally ratified by the Representative Body. Let each section, while developing its own interest in particular, strive by friendly co-operation to help the others.

Dr. James Fenton (chairman, Public Health Committee): It was desirable that all three sections—general practitioners, consultants and specialists, and public health officers—should work together as one. As representing the public health side he was very anxious that this should be done.

Dr. J. C. Arthur (Gateshead) said that while these committees were autonomous they should be able to correlate and co-ordinate their actions when matters affecting the profession came up.

The Chairman of Council hoped the meeting would not pass this resolution, which suggested that it was expected that the autonomous bodies would do things of which the main body would disapprove. "Don't query the autonomy of these bodies. Leave it to them to bring their problems to us and leave it to us to deal with them in a common-sense way as we have always done in the past."

It was unanimously agreed to pass to the next business.

The meeting terminated at 5 p.m.

CONSULTANTS AND SPECIALISTS TERMS AND CONDITIONS OF SERVICE

A meeting of the Central Consultants and Specialists Committee was held at B.M.A. House, London, on March 24, Mr. R. L. Newell presiding.

Since the last meeting of the committee the Ministry's proposals concerning terms and conditions of service of hospital staff have been received by the Joint Committee (the committee presided over by Sir Lionel Whitby, of which the Central Committee is one of the constituent bodies) and referred for regional consideration and report. It was decided to devote a special all-day meeting on April 28 to the consideration of this document.

In some brief discussion it was stated that the Joint Committee was in no way committed to any part of the proposals. The views which the Joint Committee had put forward were in general the views of the Central Committee. It would be for the Central Committee to examine the proposals strictly on their merits, and instruct its representatives on the Joint Committee accordingly.

A member said that before making any decision on the betterment factor it was desirable to have some communication with the general practitioner side of the profession, so that the two branches would act in liaison. The chairman assured the committee that this was already being done.

Dr. Rowland Hill then submitted a report from the Executive Committee on matters referred to it and other matters which had arisen between meetings. One recommendation which had previously been referred back concerned the liability of full-time specialists to undertake domiciliary visits. A revised recommendation, which was agreed to, laid it down that in principle full-time specialists should not undertake domiciliary visits

except where there is no part-time specialist available to provide the necessary services or where the character of the specialty is such as to necessitate the attendance of a whole-time specialist. It was further agreed that a full-time specialist who desired to engage in domiciliary work should have the right to transfer to a part-time basis at the maximum number of sessions.

Full-time Specialists and Private Practice

A discussion took place on this subject, particularly in relation to the treatment of patients in private hospital beds. Attention was called to a communication from the Ministry explaining the manner in which patients might be referred from one specialist to another—that is, either as private or as "public" patients. It appeared that the Ministry envisaged a situation in which part-time specialists might contract to render treatment to patients in pay-beds without the right to charge the patients a fee. To this the committee was strongly opposed. It felt that here, as in the case of domiciliary visits, it should not be part of the duties of full-time officers to undertake the treatment of private hospital patients where part-time specialists were available for the purpose.

The propositions eventually agreed to by the committee were to the effect that full-time specialists should not be required to undertake the treatment of patients in private hospital beds, but that they should be permitted to do so (without fee) when their services were sought by a professional colleague; and also that full-time specialists who wished to participate in the treatment of private patients should have the right to transfer to a part-time basis at the maximum number of sessions. It was also agreed that in no circumstances should a specialist undertaking to perform part-time services be offered a contract containing a clause requiring him to treat patients in pay-beds without the right to charge professional fees. It had been suggested that the Government contemplated that part-time officers might agree to accept remuneration through additional sessions from regional boards in lieu of charging private patients.

Payments by Private Patients

Instances were brought forward from various areas of private hospital patients seeking to evade payment for the professional service they had obtained. One regional committee had suggested that a form which would be a legally binding contract to ensure payment be devised for signature by any patient admitted to a pay-bed. Such a form had been devised by the solicitors to the Association. It set out that the signatory, having read the relevant sections of the Act, agreed to pay the charges for accommodation and the cost of any services rendered by a practitioner in accordance with the scale in force.

The committee passed a resolution that a person who had agreed to receive hospital treatment privately, and had been admitted to a pay-bed, should not subsequently be allowed to claim the specialist services rendered on that occasion as a "public" patient.

On the question of the confidential nature of medical reports, on which some anxiety had been expressed by specialists, the committee agreed that outside bodies—it was explained that Government Departments and other third parties were in view—should not be permitted to have access to, or copies of, hospital records regarding the treatment or condition of patients without the knowledge and permission of the responsible clinician and the consent of the patient.

Representation of Full-time Specialists

A letter from the Association of Whole-time Specialists expressed some concern lest with the setting up of the Joint (Whitby) Committee and the disappearance of the previous Negotiating Committee the representation of the views of full-time specialists should be absent from the body which doubtless would undertake the final negotiations on the permanent contracts. Some feeling had been expressed that the part-time specialist was more favoured in the draft terms than the full-time salaried specialist. It was recognized that the interests of full-time specialists did at certain points diverge from those of part-time specialists, though there was no real conflict and

no consciousness of opposing interests on the Whitby Committee. At the same time it was felt that in the absence of adequate representation of full-time specialists it was possible that some interest of theirs might be overlooked, and it was agreed to ask the representatives of the Central Committee on the Joint Committee to consider the desirability of whole-time specialists' representation.

On the proposition of Dr. James Fenton the Central Committee agreed to co-opt to its membership Dr. N. J. England, who would be able to speak from his experience as a tuberculosis officer. Mr. J. P. Cocker had been nominated by the British Dental Association as a liaison officer to attend the meetings of the committee in the capacity of an observer.

Many other subjects occupied the committee during a long sitting, and some were referred for further exploration to the Executive.

B.M.A. LECTURES ABROAD

B.M.A. lectures have been given abroad in the last few months by Mr. N. R. Barrett on chest surgery (Denmark), Dr. J. S. Heller on pharmacology (Austria), Professor Geoffrey Jefferson, F.R.S., on neurology (Austria), Professor M. J. Stewart on pathology (Czechoslovakia), and Mr. C. Price Thomas on chest surgery (Spain).

Dr. Heller reports that though the number of medical students in Vienna is decreasing there are still far too many. If they continue to qualify at the present rate, many doctors will be unemployed in the near future.

There is a stock of pre-war apparatus comprising very costly items, usually of German make. (It appears that none of these things have been looted, though the departments of biochemistry and physiology have lost some electrical apparatus through bomb damage.) The main difficulty is the lack of simpler pieces of equipment—e.g., glassware and chemicals. Professor Wessely (biochemistry) complained particularly about the lack of ground glass. Analytically pure chemicals were obtained almost exclusively from German firms. Some departments live on their stock of chemicals, and purification on a small scale is also done, but an inland source of supply is needed.

At present Austria lacks even the simplest drugs such as aspirin. Only the supply of penicillin seems fairly adequate, owing to gifts from the occupying armies. Some drugs for research purposes are obtained through personal connexions of medical research workers with English, American, and Swiss firms. Free gifts of small amounts of new preparations would be much appreciated. The departments obtain an occasional dog, cat, or rabbit, but they cannot keep rats, mice, or guinea-pigs because they lack feeding stuffs. Not only certain types of research but also the biological standardization of drugs suffers.

Very little research in biochemistry is done, and even that is less biochemical than purely organic chemical work. No "experimental" physiology is being done. The pharmacology department seems to be the only one where research is done on a larger scale. All the apparatus bought by the late Professor R. Rossler has been saved and is in good working order. Dr. Brucke, the provisional head of the department, is working with certain Swiss firms, who provide some chemicals and journals. The work is handicapped by the lack of animals, but interesting work is done—e.g., investigations on the effect of drugs (sulphonamides, folic acid) on the metabolism of micro-organisms, and on the structure of cholinesterases.

Apparently there is no research in pathology. Even material for urgent diagnostic work is said to be lacking. Cover-slips, for instance, have to be used again and again. The famous pathological museum is intact.

In Professor Fellingner's unit haematological problems are being studied—e.g., the mechanism of action of urea on leucocytes. Professor Lauda's unit is interested in antihistamine substances, but lacks the appropriate preparations from British or American firms.

Mr. Price Thomas found that all the young doctors in Madrid and Barcelona are learning English. The greatest shortage appeared to be of x-ray films, so that most of the radiological investigations are by fluoroscopy. This seemed to be a handicap, and chest surgery is not as advanced there as in Britain.

RELEASE OF MEDICAL OFFICERS FROM H.M. FORCES

The Central Medical War Committee has been advised by the Service Departments of the following arrangements for the release of medical officers from H.M. Forces during the second quarter of 1949 :

Royal Navy

April	Group 101 and Group 102
May	Group 103 and Group 104
June	Group 105 and Group 106

R.A.M.C.

April 1-14	Group 106
April 15-28	Group 107
April 29-May 13	Group 108
May 14-28	Group 109
May 29-June 12	Group 110
June 13-27	Group 111
June 28-July 10	Group 112

R.A.F.

April	Group 101 and Group 102
May	Group 103 and Group 104
June	To be announced later

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, WallSEND.

Urban District Councils.—Denton, Droydsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

B.M.A. LIBRARY

The following books have been added to the Library :

- Abely, A. M. P., Assailly, A., and Laine, B.: *Les Facteurs Vasculaires et Endocriniens de l'Affectivité*. 1948.
 Acquisitions Médicales Récentes (Les). 1947.
 Allen, F. H.: *Psychotherapy With Children*. 1947.
 American Public Health Association: *Diagnostic Procedures for Virus and Rickettsial Diseases*. 1948.
 Beattie, J. M., and Dickson, W. E. C.: *Textbook of Pathology*. Fifth edition. 2 volumes. 1948.
 Beger, H.: *Leitfaden der bakteriologischen Trinkwasseruntersuchung*. Zweite Auflage. 1948.
 Bérillon, E.: *La Science de l'Hypnotisme*. 1946.
 Boquet, P.: *Venins de Serpents et Antiveniens*. 1948.
 Bourne, G.: *An Introduction to Cardiology*. 1949.
 Brill, A. A.: *Lectures on Psychoanalytic Psychiatry*. 1948.
 Butler, C., and Erdman, A.: *Hospital Planning*. 1946.
 Calewaert, D.: *Conception Physique de la Vie*. Deuxième édition. 1947.
 Christian, H. A.: *Bright's Disease*. 1948.
 Conybeare, Sir J. (Editor): *Textbook of Medicine*. Ninth edition. 1949.
 Corner, G. W. (Editor): *Autobiography of Benjamin Rush*. 1948.
 Crile, G. (Editor): *George Crile: an autobiography*. 2 volumes. 1947.
 Curies del Agua, A.: *El Colapso Circulatorio*. 1946.
 Curran, D., and Guttman, E.: *Psychological Medicine*. Third edition. 1949.
 Daniels, F.: *Outlines of Physical Chemistry*. 1948.

Correspondence

Exchange Control Medical Advisory Committee

SIR,—I have recently had some correspondence with the Financial Secretary to the Treasury (the Rt. Hon. W. Glenvil Hall, M.P.) on the functioning of the Exchange Control Medical Advisory Committee, and I have his permission to send you the following extracts from his letter, in the hope that the explanation given and the statements therein made will help to clear up a certain amount of misunderstanding about this committee.

"The Exchange Control Medical Advisory Committee has no powers to make grants of any kind. What it does is to advise the Treasury on all applications for health treatment abroad, and it recommends whether or not the necessary foreign currency should be provided. It has nothing to do with who puts up the sterling to meet the expenses.

"In practice, the majority of cases with which the committee deals are tuberculosis cases, and most of the members of the committee (which is a panel of independent consultants) are, in fact, leading tuberculosis specialists. So far as tuberculosis cases are concerned, the great majority of all applications which come before them are approved. The approximate figures since the committee was set up in December, 1947, are 1,000 approvals out of 1,100 applications.

"The way that the committee works is that any sick person in the country can apply through his own doctor to the committee. The doctor furnishes full medical reports, and these reports are considered by two members of the committee, and, in the event of their disagreement, by the chairman as well. The criterion under which the committee works is that treatment abroad must be essential to the recovery of the patient's health, and that such treatment cannot be obtained anywhere else in the Sterling Area. How this works out in practice is, of course, for the committee to decide, but, as I understand it, the committee would not normally approve applications in cases of tuberculosis which were too far advanced for treatment abroad to hold out any hope of recovery. I am sure you know, in certain types of case, high-altitude treatment would do more harm than good by causing the disease to flare up. In any case it would be a disservice to the country, and no kindness to the patient or to his family, to allow a sufferer to go abroad and to incur extremely expensive treatment in foreign sanatoria with no hope of ultimate recovery.

"I think you can take it that the committee takes its duties very seriously, and that its members will always give the application the benefit of any doubts that they may have. I feel confident that in any case where the committee thinks that the patient has any real chance of recovery by going abroad currency will be provided. Of course, even leading tuberculosis specialists may make mistakes, but I think it is also fair to say that the members of the committee are as a rule in a better position to judge from the general nature of the case whether or not treatment abroad will be beneficial than is the doctor who puts forward the application. It would be clearly impossible for the committee to see the patients themselves, nor is it their function to do so; but if they are in any doubt they are at liberty to ask the doctor for further information, and they do not hesitate to do so."

—I am, etc.,
House of Commons.

WALTER ELLIOT.

SIR,—One hears that Mr. Douglas Jay, M.P., has been defending the Exchange Control Medical Advisory Committee against adverse criticism. It may interest your readers who have had no experience of this body to know of the method by which (so far as pulmonary tuberculosis is concerned) it reaches its conclusion upon whether or not to grant currency permits. The doctor—usually the chest physician of the area in which the applicant lives—sends the medical case history and the latest x-ray film of the patient to the secretary of the committee, and upon this slender evidence the case for or against is judged. The opinion of the physician in charge of the case, who knows the patient from long acquaintance and from every aspect, and which may be considered to be of the first importance, appears to carry no weight and to be ignored.

It is an axiom of medical practice especially applicable to the disease of tuberculosis, and particularly to pulmonary tuberculosis, that no one part of the whole investigation of a case can be exalted above the rest, that the lesser cannot be made to include the greater. But that is what the committee does. Without knowledge of the applicant's mental, physical, and clinical attributes it decides upon the case history and

upon the shadows in an x-ray film the question an unfavourable answer to which may have the most serious repercussions upon the sufferer. In short, it reaches a decision upon evidence that not one member of the committee would accept as sufficient in his private practice to discharge his duty to his patient. One might as well expect a court of law to decide innocence or guilt without hearing both sides and without a jury.—I am, etc.,

Folkestone, Kent.

B. G. EDELSTON.

Betterment on Mileage

SIR,—At a recent meeting at Reading we were told that the Mileage Fund has been increased threefold, but that, as it has to be spread over a list of patients that has increased about two-and-a-quarterfold, the effect in Berkshire is to increase the mileage unit from 2s. 1d. to approximately 2s. 6d.—i.e., about 20%, which we considered inadequate.

The Mileage Fund was not intended as a motor-car expenses fund but as an increase in the capitation fee to balance the time-distance factor. Surely, then, we should press for the Mileage Fund to be increased sufficiently to raise the mileage unit in the same proportion as the raising of the capitation fee—namely, to 170% or 185%.—I am, etc.,

Crowthorne, Berks.

H. D. FORBES FRASER.

Senior Hospital Officers

SIR,—Examination of the Minister's proposals for remuneration raises immediately the question, Who or what are senior hospital officers? The answer will, it appears, lie in the empirical foundation of an establishment of specialists for each region, and thus for each hospital.

Considerable numbers of specialists are likely to find that their particular post is not included in the establishment and that they will therefore be mustered and paid at the very much lower level of senior hospital officer.

To enforce the acceptance of these posts is, I submit, one of the purposes to be served by the induction of financial stress by delayed settlement. I submit that it must be the duty of the Negotiating Committee to ensure that the specialist establishment is both elastic and personal.—I am, etc.,

Burton-on-Trent.

RANDLE LUNT.

Breach of Terms of Service

SIR,—Under "Medico-Legal" in the *Journal* of Feb. 26 (p. 371) I read of one of our colleagues who has been convicted and heavily fined (150 guineas) for giving a post-dated intermediate certificate on Form Med. 2A, and an unsigned, undated final certificate on Form Med. 2B. Admittedly this is a breach of the regulations, but surely the penalty is out of all proportion to this purely technical offence, and comparable to "hanging a man for stealing a sheep."

In considering the recommendation to the executive council the Medical Service Committee "took into account the practitioner's attitude in this case," which to me is quite irrelevant and should have no bearing on the case at all. We are not children to be treated in this way.

Also, what happens to the 150 guineas? Does it go back into the central pool? In which case, do we all get a bite out of it?—I am, etc.,

Nottingham.

T. GORDON TRESIDDER.

* * The 150 guineas is not returned to the central pool. This money is saved by the Exchequer, in that it is not paid to anyone.—ED., *B.M.J.*

Demands on the Table

SIR,—We are in great danger of being drowned in our own verbosity. We are being inundated by a spate of Spens, betterment factors, graduated capitation fees, global sums, and pools (or puddles). In fact we are creating a situation that the Minister loves—in his opponents.

Let us put our demands—yes, demands, like coal miners and bus conductors—on his table, and if they are not fulfilled I suggest that we just refuse to sign any State certificates. We must see and attend to our patients. I should imagine that the Act would last about two weeks.—I am, etc.,

Coventry.

JOHN HALE POWER.

United Action

SIR,—In all the correspondence published in the *Journal* since July last year very little mention is found of the two most fundamental problems facing the profession to-day. These are, first, the need to educate the general public in how the new Service should be used, and, secondly, how to overcome the apathy in the profession itself towards its fight for security.

Patients are tending more and more to consider their doctor as a universal provider of various remedies which they, the patients, think may do them good. The old approach used to be, "Doctor, I have a pain in my back; will you please advise me?" Now it is, "Doctor, will you give me a belladonna plaster for my back and a few aspirins, and as I'm here I might as well have a chit to get my eyes tested and a few pills for my wife's constipation."

Calls late in the day for patients who have been ill for a week, unnecessary night calls, and every conceivable dodge to avoid the queue at the surgery—all these are making the average general practitioner's life a constant struggle against unreasoning demand. This struggle would be greatly eased if the Government would run a campaign in the national Press. We've had "Keep death off the road": why not "Keep the doctor in bed"—at night at any rate?

The apathy in the profession is a problem in the solution of which we deserve and can demand no outside help. At a recent meeting of the local B.M.A. Division at which the motion for discussion was whether we should insist on 185 as the betterment figure, or whether we will accept the figure of 170 to be put to the Minister, there were present not more than 30 members out of a possible total of several hundred. It is significant that a similar meeting a year ago would have produced ten times this number. Are we all so fed up with the long-drawn-out negotiations that we feel that it is of no avail to continue the fight? If so, the outlook for the profession is indeed grim and the path downwards to a completely controlled State service steep and short.

If our leaders do not inspire our confidence and rouse our enthusiasm we must replace them. If, on the other hand, we believe that they are really prepared to fight for our just demands we should give them the necessary backing in the Divisions so that they can negotiate with the knowledge that they have the full weight of the profession behind them. "United we stand, divided we fall"—never was this so true as it is to-day.—I am, etc.,

Lewes, Sussex.

J. P. MATTHEWS.

Graduated Capitation Fee

SIR,—At the risk of being unpopular with the "have-nots" I think the subject of the proposed graduated capitation fee demands consideration. I trust the profession will consider the effects carefully before agreeing to such a method of payment. I for one object to subsidizing the income of a practitioner who may be a part-time specialist, anaesthetist, business man, ardent golfer, or just lazy. Surely the capitation fee is already graduated by income tax. I have taken the trouble to work out the net spendable income per caput after deduction of expenses and income tax, and assuming that we obtain the proposed increase of £16½ million in the pool. I have made the following assumptions:

(1) The doctor has a wife and two children. (2) Average mileage fee of £45 per 1,000. (3) Maternity cases per annum equal 20 per 1,000. (4) Expenses of £400 for 1,000, £600 for 2,000, £800 for 3,000, £1,000 for 4,000.

Making allowance for superannuation and income tax the fee per caput is:

	Uniform Capitation Fee of 25s.		Capitation Fee of 35s. for First 1,000 and Thereafter 18s.	
	£	d.	£	d.
For first 1,000	15	9	22	0
For second 1,000	14	5	9	8
For third 1,000	9	10	7	1
For fourth 1,000	8	4	6	4

It will be seen from these figures that if the fee for the first thousand is to be raised then I think it should be approximately 28s. This would achieve a fairly severe graduation.

There appears to be a good deal of animosity to doctors with large lists who are now reaping financial reward. For many years these men have been slaving in unhealthy, sordid surroundings often for little or no financial reward, and for this reason have had to take on large lists. They have none of the pleasant benefits of practice in residential or country areas. The imputation that a doctor is incapable of attending to lists of 3,000-4,000 is untrue, and that as a result he should have a lower capitation fee. The converse could be argued. Does a miner, working overtime, work less effectively? He may, but he gets paid time and a half.

I think it is generally agreed that the rural practitioner is badly hit and that mileage should be much more heavily weighted. Subsidizing the doctor in residential areas is unfair. They should gradually move to under-doctored areas. One hears too often of the patient who was visited privately on regular occasions before July 5 but is now ignored.—I am, etc.,

East Wemyss, Fifeshire.

I. G. MEIKLEJOHN.

Retain Assistantships

SIR,—I have been waiting to see, if some abler pen than my own would reply to certain letters appearing recently in your correspondence columns advocating the abolition of assistantships. These letters were a source of amazement to me. When I left hospital I went as assistant to two partners in a town in Cornwall. Within six months I was given a partnership. Recently my partner and I have found our practice much too big and looked around for an assistant with a view to making him a partner. We found a suitable man. The salary is £750 and free house. He worked so well we gave £100 bonus, and in April he will become a partner with a quarter share. My present partner and I share the other three-quarters evenly. In five years he will be a full and equal partner.

How on earth do those who advocate abolition of assistantships think a young man is going to learn his job? Do they really think that what they learn as students and in house jobs is going to fit them for the onerous specialty of general practice? Do they think that in a large practice with, say, 12,000 patients the partners are going to accept some stranger appointed by a board? I have spoken to our local authorities, and the view is that in such cases the appointments board would appoint a man selected by the firm of doctors concerned—which is only right, for an unsuitable partner is a source of irritation and weakness to the team. I have no doubt that there are ageing men who seek to postpone retirement to abject poverty by employing an assistant. There is no compulsion to stay on, is there?

Before this Act certain young men (and women) objected to buying houses and practices. Now apparently they object to learning their job before being allowed to attend the public.—I am, etc.,

A. B. C.

Registrars Group at Bristol

SIR,—May we, through the courtesy of your columns, announce the formation by the registrars of the hospitals in the Bristol area of a Registrars Group? It is hoped to extend invitations to join this group to registrars in the South-west Region, and would those interested please write to the secretary?—We are, etc.,

JOHN H. CHALLENGER.

W. R. BLACK.

FRANK L. DYSON.

T. J. BUTLER.

J. E. MALCOLM.

163, Wellington Hill West,
Westbury-on-Trym, Bristol.

Secretary, Subcommittee
Registrars Group.

Effect of Income Tax

SIR,—I wonder whether some of the people with very large lists have had time to stop and consider the income tax they will have to pay in 1½-2 years' time. Put briefly, the facts are these. On a net, not gross—repeat net—income of:

£2,500 the last £500 is worth £235 to the individual
£3,000 the last £500 is worth £212 10s. to the individual
£3,000—£4,000 the last £1,000 is worth £375 to the individual

and so on proportionately downwards very steeply until you are earning only sixpence in the pound. Very few G.P.s are

likely to do this out of general practice alone. In plain language the last 1,000 patients would only be worth 8s. 4d. per head per annum. A married man with one child and a net income of £4,000 would pay £1,781 10s. tax.

Now there may be doctors who like to do this. It is obvious that every G.P. must work out for himself the point at which it becomes economically not worth his while to take on new patients and do more work for less money. At the present rate of remuneration the number of patients required to enable a doctor working very hard to maintain his standard of living is higher than he can do with due regard to good medicine.

If Spens is implemented as is suggested in M.22 a doctor with a list of 4,000 would have an income approaching £6,000 a year gross. With allowances of £2,000 per annum expenses this would mean £4,000 a year net, and so he would come into the tax range outlined above. This would mean, I think, that lists would tend to come down to nearly 3,000 in densely populated areas. In sparsely populated areas the new scale would make life much easier and maintain the standard of life due to the individual—the patient and the doctor. It would also again help that enormous pool of young doctors who at the present moment cannot get into general practice, because it would encourage G.P.s to take on partners once their lists were over 3,000. Furthermore, it would help those patients who have at present to wait so long in the waiting-room in densely populated areas.

These, Sir, are a few ideas for consideration by the profession at large. I think they do contain food for thought both to the medical profession and also, and by no means least, the Ministry itself.—I am, etc.,

Hadlow, Kent.

J. B. MARSHALL.

General Practitioner Surgeon

SIR,—I am grateful to Mr. John C. Nicholson (*Supplement*, March 12, p. 143) for restating the more or less stock arguments of full-time surgeons to the practice of surgery by general practitioners, but he views the problem from too narrow an angle. As he says, the welfare of the patients is involved, and this must come first. Now, while I admit that practitioners as well as other surgeons make mistakes—even more mistakes to start with—there is no reason why, with an experienced colleague working with them—which in their earlier years they certainly ought to have—these mistakes should have any dire results. If the worst came to the worst and a doctor found himself confronted with something that he could not tackle he can at least sew the patient up, pocket his pride, and get a more experienced man to operate later. But in fact such occasions very, very seldom arise, for the following reason.

As I stated in my first letter, a general practitioner has to live with his mistakes, and one or two slips teach him to be extra careful of his diagnosis, quite apart from any right fear that he might start doing something that he could not perform. He may not have the skill at prompt diagnosis of the more practised surgeon, but he usually has the inestimable advantage of having seen the case many times before and so getting a dynamic instead of a static view of the disease, which may often more than compensate for lack of skill and diagnostic facilities. 90% of major surgery performed by practitioner surgeons consists of appendicectomies and a few other things which may require care but do not, in fact, require vast skill for competent performance. Nor, as performed in small hospitals, do they require all the complicated paraphernalia which is quite rightly employed in larger institutions where conditions are quite different.

Then, as I also mentioned, in such hospitals the patient comes much earlier to operation because he is a human being and not a guinea-pig, and, however anxious and persuasive the doctor, patients do persist in clinging to him rather than to the more experienced stranger, and their wishes and those of their families always have to be considered. The net result is that the practitioner surgeon has a much less complicated task to perform, and, owing to his combined responsibility and practice while every detail is fresh in his mind, his skill in making an exact diagnosis and judging when to operate rapidly increases. The further result is that practitioners who practise surgery see less and less acute surgical emergencies,

for they have been treated earlier, and although I have no statistics to quote I have little doubt that most of the emergencies and late surgical cases which are sent into our big hospitals are sent in by practitioners who do no surgery, and for that very reason. If we wish to save these lives and the disability and human misery that these late cases cause we shall do it not by preventing practitioners from doing surgery, as Mr. Nicholson wishes, but by raising their standards and providing better facilities and safeguards so that still more can take an active share in such work, with due precautions against abuse.

May I draw two analogies which really are germane to the subject? No one disputes the wonderful work that can be done by our giant telescopes, but you do not need to go to an observatory to see if the stars are shining, for our senses are in fact much more sensitive than all but the most elaborate instruments; and a doctor who has learnt to listen to the patient's sensations and to use his own senses has in 90% of cases (probably more) no need to refer to x rays or other instrumental means of diagnosis. If he cannot be sure of his clinical diagnosis without these aids he certainly ought to send his case to a more experienced operator.

My second analogy is that no one in his senses would try to make all the roads of this country into main roads. If he did, the result would be colossal expense and the destruction of many of the amenities that people have learnt to enjoy. But it is on just such a task that the hospital authorities seem bent. Parliament and people have begun to gasp at the expense involved. They will soon begin to weep at the hospital services that will follow, for patients are not just material for surgeons to cut about, they are human beings with powers of vitality and response which are seldom or never evoked in large hospitals but which are the everyday experience in our more intimate smaller ones, where some personal word about the family or local life puts new life into the patients and more than makes up for our lack of surgical skill. If Mr. Nicholson doubts these things he and his fellow surgeons should just come and look round our hospitals intent on learning instead of criticizing, and with all their faults—which I am the first to admit—he would find much to make him hesitate before destroying instead of improving a system that has done so much for patients and for medicine in so many of our smaller towns. There is ample scope for both types of surgeons as well as hospitals, and it is a pity that some surgeons are not as eager to learn from practitioners as we are to learn from them, for at least we see much more of the end-results of their operations than they are ever likely to do. Co-operation rather than domination or opposition is the road to successful working, and surgery is more than mere operating.

I have deliberately omitted mention of urgent surgery, but this also comes into the picture.—I am, etc.,

Winsford, Cheshire.

W. N. LEAK.

POINTS FROM LETTERS

Health Centres

Dr. HAROLD H. SANGUINETTI (London, W.8) writes: . . . How much longer are we to wait for health centres providing x-ray examinations and pathological investigations for the general practitioner direct? What about physical treatment centres? What about closer association of the general practitioner with the work of our hospitals? Are none of these things worth fighting for? Judging from a letter circulated to general practitioners and just received from the London Medical Committee this committee has little conception of what a health centre should be. Where not less than three and not more than six practitioners are grouped together we have *ipso facto* a health centre, but surely not the health centre envisaged by the late Lord Dawson of Penn. By all means see that we are properly paid, but at the same time do not let us miss the opportunity of reorganizing the profession.

Panel of District Nurses

Dr. HERBERT SIMON (London, N.3) writes: . . . I suggest that the Minister should with all speed and with the help of the local authorities establish a panel of district nurses, or at least a panel of men and women sufficiently trained in elementary home nursing, who should be available at any time of the day or night. The names and telephone numbers of such personnel should be available at any time at the local police station.

H.M. Forces Appointments

ARMY

Colonel (Temporary Major-General) E. B. Marsh, M.C., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Major-General.

Colonel (Local Brigadier) D. C. Monro, C.B., C.B.E., late R.A.M.C., retired, re-employed, has been restored to the rank of Major-General on ceasing to be re-employed.

Colonel W. M. Cameron, O.B.E., late R.A.M.C., having attained the age for retirement, is retained on the Active List supernumerary to Establishment.

Colonel A. R. Ross, late R.A.M.C., has retired on retired pay. Lieutenant-Colonels P. F. Palmer, O.B.E., C. E. Eccles, O.B.E., and D. Bluet, O.B.E., from R.A.M.C., to be Colonels.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel J. J. O'Dwyer, C.B.E., has retired on retired pay and has been granted the honorary rank of Colonel.

Lieutenant-Colonel J. M. Mackenzie, C.B.E., M.C., has been restored to Establishment.

Majors R. H. Hunt, O.B.E., E. J. Pryn, P. L. E. Wood, D.S.O., M.B.E., G. M. Denning, and J. J. Sullivan to be Lieutenant-Colonels.

Captain R. M. Vanreenen to be Major.
Short Service Commissions (Type "B").—Captains P. T. Harper, P. K. Murphy, L. W. H. Bertie, H. P. Swan, J. Aitchison, and G. J. O'Connor to be Majors.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Captain (War Substantive Major) J. S. Richardson, from Supplementary Reserve of Officers, to be Major, and has been granted the honorary rank of Lieutenant-Colonel.

Captain E. I. B. Harvey, from Supplementary Reserve of Officers, to be Major, and has been granted the honorary rank of Colonel.

Captain A. C. Stevenson, from Supplementary Reserve of Officers, to be Major, and has been granted the honorary rank of Lieutenant-Colonel.

Captains E. A. Heaslett and A. C. Kanaar, from Supplementary Reserve of Officers, to be Majors.

Captain (Acting Major) J. A. Chapel to be Brevet Major.

INDIAN MEDICAL SERVICE

Major (War Substantive Lieutenant-Colonel) D. J. P. Parker has retired, and has been granted the honorary rank of Colonel.

Lieutenant-Colonel E. C. A. Smith has retired.

Major W. J. F. Young, D.S.O., M.B.E., has retired and has been granted the honorary rank of Lieutenant-Colonel.

Major F. W. Whiteman, O.B.E., has retired but continues to be borne on the Special List (ex-Indian Army) British Army while employed with the Pakistan Armed Forces.

War Substantive Major H. R. Cara has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: J. A. Byrne, M.B., F. C. Harris, M.R.C.S., and T. A. Martin, L.R.F.P.S., Medical Officers, Gold Coast; J. C. G. Lockyer, M.B., B.M., L. F. B. Delany, M.B., and T. W. Robson, M.R.C.S., Medical Officers, Tanganyika; E. Robinson, M.B., and B. A. Payne, M.R.C.S., Medical Officers, Nyasaland; J. Belej, M.D., Temporary Medical Officer of Health, Gold Coast; Z. P. Walczak, M.B., Supernumerary Medical Officer, Leeward Islands; P. J. Bourke, L.R.C.P.S., L.R.F.P.S., Senior Medical Officer, Nyasaland; E. Bradbury, M.B., D.T.M.&H., Senior Medical Officer of Health, Sierra Leone; A. B. Brereton, M.B., D.M.R.E., Radiologist, Gold Coast; C. N. Latham, M.B., D.T.M.&H., D. W. McLaren, M.B., D.T.M., W. McLelland, M.B., D.T.M.&H., C. P. Murray, M.B., and J. L. McLetchie, M.B., D.T.M.&H., Senior Medical Officers, Nigeria; B. D. Molesworth, M.B., Medical Superintendent, Leper Settlement, Federation of Malaya; W. S. Urniston, M.B., D.T.M.&H., Deputy Director of Medical Services, Gold Coast; W. R. Phillips, M.B., D.T.M.&H., Surgical Specialist, Gold Coast; A. L. Shield, F.R.C.S., D.T.M.&H., Tuberculosis Specialist, Federation of Malaya; K. R. Steenson, M.B., Deputy Director of Medical Services, Fiji; J. H. Strahan, M.B., D.P.H., D.T.M.&H., Professor of Social Medicine and Hygiene, Singapore; H. Wands, M.B., Deputy Director of Medical Services, North Borneo; G. Watt, M.B., D.T.M.&H., Assistant Director of Medical Services, Gold Coast; G. F. Baxter, M.R.C.S., Senior Medical Officer, Jamaica; L. J. Chwatt, M.D., D.T.M.&H., Senior Malariologist, Nigeria; G. V. Harry, F.R.C.S., Senior Surgeon, Jamaica; A. A. Reece, M.D., Medical Officer, Grade B, Trinidad; C. E. E. Stevens, M.B., Medical Superintendent, Cunningham Hospital, Leeward Islands; R. D. P. Eaton, M.B., and D. McKinley, M.R.C.S., Medical Officers, Sierra Leone; I. H. Gordon, M.R.C.S., Pathologist, Nigeria; C. R. C. Rainsford, M.D., D.T.M., Senior Medical Officer in Charge, Zanzibar; A. W. Williams, M.D., D.T.M.&H., Medical Superintendent, Mulage Hospital, Uganda; A. A. Bonner, M.D., D.P.H., Medical Officer (Health), Jamaica; R. M. L. Sull, M.R.C.S., Medical Superintendent, Mental Hospital, Barbados.

Association Notices

RADIOLOGISTS GROUP

A meeting of the Radiologists Group will be held at B.M.A. House on Monday, April 25, at 2 p.m. to receive a report from the Group Committee and to discuss matters of interest to members. It is hoped that as many members of the Group as possible will attend this meeting.

Diary of Central Meetings

Branch and Division Meetings to be Held

BARNSELY DIVISION.—At St. Helen's Hospital, Wednesday, April 6, 8.30 p.m. Film: "Angina Pectoris."

BISHOP AUCKLAND DIVISION.—Thursday, April 7, Annual dinner.

GREENWICH AND DEPTFORD DIVISION.—At Chiesmans Restaurant, 33, Lewisham High Street, London, S.E., Thursday, April 7, 7 p.m. Annual dinner and dance.

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Tuesday, April 5, 8.30 p.m. Address by Lord Horder.

KESTEVEN DIVISION.—At George Hotel, Thursday, April 7, 7.30 p.m. for 7.45 p.m., Dinner. 8.30 p.m., Address by Mr. W. Buckley: "Some Aspects of Thoracic Surgery."

RICHMOND DIVISION.—At Royal Hospital, Richmond, Tuesday, April 5, 9 p.m. Professor H. V. Dicks: "The Role of the General Practitioner in Mental Hygiene."

ROCHESTER, CHATHAM AND GILLINGHAM DIVISION.—At All Saints' Hospital, Chatham, Thursday, April 7, 8.30 p.m. Clinical meetings. All practitioners in the area of the Division are invited.

WESTMINSTER AND HOLBORN DIVISION.—At City Hall, Charing Cross Road, London, W.C., Thursday, April 7, 8 p.m. Special meeting to hear reports of Representatives to Special Representative Meetings held on March 29 and 30.

Meetings of Branches and Divisions

PLYMOUTH DIVISION

Professor Lambert Rogers gave a B.M.A. Lecture on "Sciatica" on March 11. He said that the last twenty years had brought about great changes in our views of the cause and treatment of sciatica. He was not speaking of symptomatic sciatica due to malignant disease in the pelvis or elsewhere, but of the so-called idiopathic variety, of whose cause many and varied views had been held in the past. Seventeenth-century writers called it "hip-gout," and Shakespeare associated it with the hip. Other joints, such as the sacro-iliac, had been held responsible. Then the great sciatic nerve had been described as reddened and swollen in sciatica, but, as Sir Charles Symonds had pointed out, no one had ever seen it in this state. Wiedhoff in 1927 had demonstrated that anaesthetic blocking of the sciatic nerve failed to relieve the pain but that sacral anaesthesia did so, and that therefore the lesion was higher up.

They now knew that it was a root lesion that caused sciatica, and any irritant lesion of the long roots which made up the nerve might cause it. Instances had been cited of both extra- and intra-dural tumours causing sciatica, and also of a foreign body in the cauda equina. The commonest cause, however, was a lesion of an intervertebral disk. A history of injury could not always be obtained, and disk degenerations and nuclear extrusions might be due to other factors such as dietetic deficiency (F. L. Golla), or a congenital displacement of the notochord, as had been suggested by Craig Mooney. It was necessary to exclude the presence of tumours or massive disk herniations in cases of persistent sciatica. If they were excluded, conservative measures were indicated, and surgery should be reserved for intractable cases which had failed to respond to such measures.

A discussion followed. The chair was taken by Dr. H. G. Ludolf, and a vote of thanks to the speaker was proposed by Mr. H. F. Vellacott and seconded by Dr. T. T. P. Murphy.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 9 1949

MEDICAL FITNESS FOR AIR TRAVEL

BY

Sir HAROLD WHITTINGHAM, K.C.B., K.B.E., LL.D., F.R.C.P.

Air Marshal, R.A.F. (ret.); Director of Medical Services, British Overseas Airways Corporation

A. BUCHANAN BARBOUR, O.B.E., M.R.C.S., F.R.Ae.S.

Chief Medical Officer, British European Airways Corporation

AND

J. C. MACGOWN, D.F.C., M.D., Ch.B.

Wing Commander, R.A.F.V.R.; Medical Adviser, British South American Airways Corporation

Those who are not well acquainted with the physiological problems of flying, particularly of long flights on a world-wide basis, doubtless find difficulty in assessing the fitness of certain individuals for air travel. To help the practitioner to advise on such cases as may be referred to him a tabulated statement has been prepared, based on experience gained in commercial and Service aviation, especially in connexion with the transport of casualties during and since the war.

In the first column of the accompanying Table the commoner medical conditions on which an opinion is likely to be required regarding suitability for air travel are listed and arranged in alphabetical order for ease of reference. In the second column the limiting factors of the disease are given: any person whose condition falls below the standard set here should be advised against travelling by air, except possibly on short flights of about an hour's duration at low altitudes under good flying conditions. Essential facilities to be provided and precautions to be taken by the passenger concerned during flight are indicated in the third column, and in the fourth column there is a note on the advisability of air travel for those suffering from each disease in question.

The advice given in the Table is in general terms and is particularly applicable to flights of over four hours' duration in public air transport flying at altitudes between 5,000 and 9,000 ft. (1,524 and 2,743 m.) and for short times at 15,000 ft. (4,572 m.) or above to circumvent a bad weather front or to avoid high ground. When the journey is by pressurized aircraft it can be assumed that the air condition of the cabin will be similar to that of an altitude of 8,000 ft. (2,438 m.) with respect to atmospheric pressure and oxygen content even if the aircraft is actually flying at 20,000 ft. (6,096 m.). The proportion of passenger aircraft which are pressurized is steadily increasing, so that in a year or two most will be of this type. Certain cases which might be rejected for public air transport might be acceptable in an air ambulance or in a privately chartered aircraft where the patient's condition would cause no offence to fellow passengers and the altitude and length of each stage of the flight could be arranged to suit the patient.

Every case must be assessed on its merits, bearing in mind the following points: (1) the medical condition and psychological make-up of the patient; (2) the effect of the patient's disability on fellow passengers; (3) the necessity or otherwise for a qualified attendant to travel with the patient; and (4) the conditions of air travel—that is, (a) the type of aircraft, particularly whether it is pressurized or not; (b) the length of the journey envisaged and the duration of the various stages, which may be as long as 10 hours when crossing the Atlantic; (c) the expected weather conditions at the time of the year, and the altitudes likely to be attained; and (d) the availability of oxygen.

Limiting Factors and Precautionary Measures

Though modern air travel is very comfortable and acceptable to the vast majority of invalids, long flights may be fatiguing even to the robust.

Patients with anaemia, even of moderate degree, suffer from anoxia at the altitudes usually flown by civil airlines, and they should have a blood transfusion to bring the haemoglobin above 50% (7 g. per 100 ml.) if an air passage is essential. Patients with acute leukaemia should not travel by air, as they readily suffer from anoxia, and haemorrhage is likely to occur with the lowered oxygen tension at altitude. If it is essential to transport such cases they should be given a blood transfusion to raise the haemoglobin level to 80%. Chronic types with pronounced splenomegaly experience respiratory distress.

Individuals who have cardiac and pulmonary lesions are apt to react badly to effects of low pressure, even at altitudes below 10,000 ft. (3,048 m.), particularly those who have had attacks of angina pectoris or coronary occlusion, as well as cardiac and renal asthmatics, chronic bronchitis, and those suffering from pulmonary tuberculosis, especially refill cases.

Patients with active tuberculosis should not travel by air unless their sputum is free from tubercle bacilli and any cavity is controlled by collapse therapy, but not within a week of a refill. If the mediastinum is fixed, the lung must be at least three-quarters expanded. Pneumo-peritoneal refill cases should not have more than

Medical Contraindications to Air Travel

Condition	Limiting Factors	Essential Facilities and Precautions in Flight	Whether Advisable to Travel by Air
1. Blood and Lymphatic System Diseases			
(i) Anaemias	Less than 3,000,000 R.B.C. per c.mm.; less than 50% Hb. (May need transfusion before flight)	Maximum altitude 5,000 ft. Oxygen must be available	Inadvisable unless aircraft is pressurized to 5,000 ft.
(ii) Leukaemias	Less than 3,000,000 R.B.C. per c.mm.; less than 50% Hb. Gross enlargement of spleen. Haemorrhages. (May need x-ray therapy before flight, which should not be within 4 weeks of the x rays)	Maximum altitude 5,000 ft. Oxygen must be available	Acute cases should be rejected, unless Hb is raised to 80% by a blood transfusion. Chronic cases inadvisable unless aircraft is pressurized to 5,000 ft.
(iii) Lymphadenoma	Enlargement of mediastinal lymph glands revealed by x-ray film. Fever of the Pel-Ebstein type	Oxygen must be available	Cases to be considered on their merits
2. Cardiovascular Diseases			
(i) Angina pectoris	Frequent or recent attacks. Electrocardiogram to exclude coronary occlusion	Maximum altitude 5,000 ft. Oxygen must be available. Movement in aircraft should be limited to minimum	Inadvisable unless in aircraft pressurized to 5,000 ft., and attack provoked only by brisk walk of about $\frac{1}{2}$ mile
(ii) Coronary occlusion	Symptoms within 12 months	Maximum altitude 5,000 ft. Oxygen must be available. Movement in aircraft should be limited to minimum	Inadvisable unless in aircraft pressurized to 5,000 ft.
(iii) Valvular lesions			
(a) Compensated	Degree of anaemia	Maximum altitude 8,500 ft. Oxygen must be available	If flight is under 8,500 ft.
(b) Uncompensated	Signs of congestive failure	—	Reject
(c) Congenital	Evidence of veno-arterial shunt (cyanosis), heart block, or severe hypertension	Maximum altitude 8,500 ft. Oxygen must be available	If flight is under 8,500 ft.
(iv) Myocardial lesions	Active disease or bradycardia. In post-diphtheria cases 6 months must have elapsed since illness	Maximum altitude 5,000 ft. Oxygen must be available	Cases to be considered on their merits
(v) High blood pressure	B.P. 200/120 mm. Hg or above. Headaches or loss of weight. Pulsus alternans. Cardiac asthma. Unsatisfactory condition of optic fundus. Albuminuria more than 2%. Cellular casts in urine	Maximum altitude 8,500 ft. Oxygen must be available	Inadvisable except in pressurized aircraft
3. Diabetes			
	Other than moderate types without cardiovascular disease, which must be stabilized by diet or insulin. Should have a recent blood-sugar estimation and report. Fasting blood-sugar level should be below 250 mg. per 100 ml.	Must adhere strictly to prescribed hours of meals and insulin injections. Not to move about at altitude more than necessary. Oxygen must be available. Hyoscine to prevent air-sickness	Only milder and moderate cases acceptable—that is, those not needing more than 50 units of insulin daily
4. Elderly			
	Unsatisfactory cardiovascular condition. In the case of a patient over 65 who is undertaking a long flight, it is advisable that a medical examination be carried out to eliminate anaemia or cardiovascular conditions. An electrocardiogram may be necessary where doubts exist	Not to move about at altitude more than is necessary. Oxygen should be available in non-pressurized aircraft	Depends on physical condition. Pressurized aircraft advisable (maximum altitude 8,500 ft.) for the very elderly
5. Gastro-Intestinal Diseases			
(i) Peptic ulcer			
(a) Quiescent and old perforation	As proved by absence of: (i) symptoms of activity; (ii) occult blood in faeces; (iii) x-ray evidence of active disease; (iv) proneness to travel sickness	Not over 8,500 ft. Hyoscine to prevent air-sickness. Carminatives for flatulence	Preferably by pressurized aircraft (8,500 ft.).
(b) Active	Pain. Occult blood in faeces. X-ray evidence. Proneness to travel sickness	Not over 5,000 ft. Limit movements in aircraft. Hyoscine to prevent air-sickness. Carminatives for flatulence. Follow dietetic advice	Normally reject. Pressurized aircraft if journey essential
(ii) Post-operation			
(a) Appendicectomy	At least 10 days must have elapsed since the operation	Not over 8,500 ft. shortly after operation. Hyoscine to prevent air-sickness	Flight should be under 8,500 ft.
(b) Herniotomy	At least 10 days must have elapsed since the operation	Not over 8,500 ft. shortly after operation. Hyoscine to prevent air-sickness	Flight should be under 8,500 ft.
(c) Other resections and wounds	Depends on condition of gut, fluid in abdomen, etc. Unable to go to lavatory unaided	Not over 5,000 ft.	Inadvisable except at 5,000 ft. maximum in pressurized aircraft
(d) Colostomy	Effect on fellow travellers	—	Reject
(iii) Haematemesis and melaena	—	—	Reject
6. Genito-Urinary Diseases			
(i) Calculus	If attacks of renal colic are frequent	Hyoscine to prevent air-sickness	Normally acceptable
(ii) Nephritis	Systolic blood pressure over 200 mm. Hg. Degree of anaemia (see Anaemia). Ascites or hydrothorax. Unsatisfactory condition of optic fundi. Albuminuria more than 2%. Cellular casts in urine. Blood urea more than 60 mg. per 100 ml.	Maximum altitude 8,500 ft. Oxygen should be available	Normally acceptable, but consider each case on its merits
(iii) Venereal	Must be free of active lesions, especially those of skin or buccal infections	—	Reject till non-infectious
7. Infectious Diseases			
	While infectious	—	Reject
8. Liver Diseases			
(i) Abscess	Those liable to burst	Maximum altitude 8,500 ft. Oxygen must be available	Normally reject. If essential, travel below 8,500 ft.
(ii) Cirrhosis	Evidence of congestive failure. Haemorrhages. Ascites or hydrothorax	Maximum altitude 8,500 ft. Oxygen must be available	Normally reject
9. Mental and Nervous Conditions			
(i) Brain tumours	Pressure symptoms. Incontinence	Maximum altitude 5,000 ft. Doctor or nurse in attendance	Normally reject
(ii) Epilepsy	Frequently occurring fits	Attendant advisable. Suitable sedative. No alcohol	Inadvisable except in milder cases
(iii) Mental disease	Non-quiescent state. Lack of control of bowel and bladder. Homicidal or suicidal tendencies	Attendant essential. Calmed with suitable sedative	Normally reject
(iv) Poliomyelitis	Not less than one month after onset (i.e., must be non-infectious). Unable to walk to lavatory. Respiratory involvement during illness	Attendant, if patient is not freely mobile. Oxygen must be available	Acceptable
(v) Other palsies	Lack of control of bowel and bladder. Unable to walk to lavatory	Attendant, if patient is not freely mobile. Oxygen must be available	Decide each case on its merits

Medical Contraindications to Air Travel—(continued)

Condition	Limiting Factors	Essential Facilities and Precautions in Flight	Whether Advisable to Travel by Air
10 Pregnancy	Must not be beyond 8th month of pregnancy. Evidence or history of repeated or threatened abortion, eclampsia, or travel sickness	Ensure that retention belt is round pelvis, not abdomen, at take-off and landing. Sit in back-facing seat, if available. Oxygen must be available. Hyoscine to prevent air sickness	If medical certificate is satisfactory and weather conditions are favourable for smooth flight at altitudes under 9,000 ft. Oxygen available. Pressurized aircraft advisable.
11. Respiratory Diseases			
(i) Asthma	Severe attacks. Cardiac or renal basis	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Consider each case on its merits
(ii) Emphysema and bronchitic conditions	Dyspnoea. Cardiac lesion. Offensive sputum	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Normally reject. Consider each case on its merits
(iii) Fibrosis of lungs	Extensive	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Normally reject. If essential, travel in aircraft pressurized at 5,000 ft.
(iv) Lobectomy and pneumonectomy	Must be more than 3 months since operation. Breathlessness on moderate exertion	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Normally reject. If essential, travel in aircraft pressurized at 5,000 ft.
(v) Pleurisy			
(a) Dry	Pain and extent of lesion. Fever	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Normally reject. If essential, travel in aircraft pressurized at 5,000 ft.
(b) Wet	If one side of chest is more than half filled (Tap if necessary)	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible. Doctor or nurse in attendance	Normally reject. If essential, travel in aircraft pressurized at 5,000 ft.
(vi) Pneumonia	Must be more than a month since recovery	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Normally reject. If essential, travel in aircraft pressurized at 5,000 ft.
(vii) Pneumothorax (artificial)	Refill must have been done more than 7 days ago. Degree of displacement. If mediastinum is fixed, lung must be not less than three-quarters expanded. Bi-lateral involvement	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Normally reject. If essential, travel below 5,000 ft.
(viii) Pneumoperitoneum	Renals must not be more than 2,000 ml at each site, and must have been done more than 7 days ago	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Normally reject. If essential, travel below 5,000 ft.
(ix) Tuberculosis			
(a) Active	Danger of haemoptysis and spread of infection	Maximum altitude 5,000 ft. Oxygen must be available. Move about as little as possible	Reject unless sputum is free from tubercle bacilli, or any cavity is controlled by collapse therapy
(b) Healed	As proved by: (i) Recent examination of sputum showing no evidence of tubercle bacilli. (ii) X-ray film of lungs. (iii) Clinical condition	Maximum altitude 8,500 ft. Oxygen must be available	Acceptable if flight below 8,500 ft. can be guaranteed
12 Tumours	Depends on site and presence of metastases and nature of complications	As required by symptoms	Depends on case

2,000 ml. of air introduced into each site. Moreover, the altitude of the flight should never exceed 5,000 ft., and oxygen must be available for immediate use in all pulmonary disease cases, whether tuberculous or otherwise. Lobectomy and pneumonectomy cases do not travel well by air, especially within three months of operation: normally they should be rejected, the degree of breathlessness on exertion being a good guide.

Those suffering from angina pectoris must have the condition adequately controlled with trinitrate, and an electrocardiogram should be done to exclude infarction: such cases can be accepted if the angina is provoked only by a brisk walk of half a mile. Cases with congenital heart lesion can be accepted for low-altitude flights if there is no veno-arterial shunt as evidenced by cyanosis, or if there is no heart-block, or severe hypertension resulting from coarctation of the aorta. Cases of high blood pressure are acceptable if the systolic pressure is not over 200 mm. Hg and the diastolic is less than 120, provided they have flown before and there is no pulsus alternans, cardiac asthma, gross albuminuria, or cellular casts in the urine: those who have not flown before may be upset by nervous tension.

Diabetics in whom the level of the fasting blood sugar is higher than 250 mg. per 100 ml. should not travel for long distances by air or at altitudes greater than 8,500 ft. (2,590 m.). Acceptable cases should be fully stabilized and keep strictly to the clock in respect of insulin and meals. They should not alter the time by their watch during the flight, but inform the chief steward of their hours of meals and their diet requirements, and have by them an adequate supply of sugar to take in the event of air-sickness. They can adjust their diabetic life to the change of time on arrival at their destination.

Elderly persons travel well at altitudes up to 10,000 ft., provided they are free from organic disease: it is advisable, however, that oxygen should be available, and where possible they should journey in a pressurized aircraft. In cases of doubt an electrocardiogram should be taken. Obese persons should be examined carefully to assess whether the fatty changes have affected the cardiovascular system, and advised accordingly.

Those with active ulcerative conditions of stomach or intestines should be warned against air travel owing to the danger of gaseous distension causing a haemorrhage or perforation. Cases of perforation or haemorrhage of the gastro-intestinal tract should not travel by air within two months of the occurrence, then only at an altitude not greater than 5,000 ft. It is essential in public air transport that all passengers should be mobile enough to go to the lavatory, aided by an attendant if necessary. Colostomy, urinary incontinence, and other odorous cases are obviously unacceptable in the confines of a public aircraft. When nephritis is present it is necessary to exclude severe anaemia, gross albuminuria, ascites, and hydrothorax before advising air travel. Infectious cases are rejected for obvious reasons. Those with cirrhosis of the liver should be rejected if there is evidence of congestive failure, haemorrhage, ascites, or hydrothorax.

Mental patients are not accepted normally, as their presence would worry the passengers and aircrew: when transported by air, they must be in a quiescent state vouched for by a mental specialist, and be accompanied by a doctor or nurse with suitable sedatives. Flying at altitude may precipitate fits in epileptics, so that only mild cases are acceptable: it is important that they should not take alcohol. Paretic cases must have full control of their bowels and bladder, and be able to walk to the lavatory,

aided if necessary. Hyperthyroidism of moderate degree is not adversely affected by air travel unless there is fear of flying, in which case sedatives should be prescribed: those with auricular fibrillation should not fly. Would-be travellers suffering from acute inflammations of the upper respiratory tract, or of the middle ear, should not fly until after the condition has subsided, as the changes in atmospheric pressure may lead to spread of infection to the paranasal sinuses and the middle ear. Those with chronic blockage of the paranasal sinuses or Eustachian tubes are unable to adjust the air pressure in their middle ears during descent, and should be advised not to fly.

It is important that expectant mothers should undergo a medical examination and obtain advice before undertaking a journey by air, and that the doctor consulted should know the proposed flight plan, its expected duration, and the altitudes likely to be attained. The difficulties of attending to a confinement or an abortion while in flight will be appreciated, so that the question of the date of expected delivery and the possibility of abortion must be carefully assessed. International airlines accept pregnancy cases up to the eighth month provided they are in good health and that oxygen is available, whether the aircraft is pressurized or not. It is important to be assured that reasonable weather conditions are forecast to avoid the danger of air-sickness or the need to use a retaining belt except at taking off and landing. Pregnancy cases should sit in backward-facing seats where these are available, so that the retention belt need not be tight at taking off and landing. They should be instructed to place the belt as low down as possible on the abdomen—just above the groins.

Children, infants, and babies travel well by air, but need oxygen at the same altitudes as do healthy adults. It is difficult to instruct very young children and babies how to equalize the pressure on either side of the ear drums on descent from altitude, so mothers should be told to feed a baby during descent and to give an older child a sweet to suck or some gum to chew to open the Eustachian orifice. If this is not done there will be pain in the ear and the child will cry: crying fortunately opens the orifice and relieves the condition.

Prevention of Air-sickness

Air-sickness is not a common occurrence in civil passenger flying, unless in "bumpy" weather. It is important, however, to take steps to prevent diabetics, expectant mothers, and those suffering from gastro-intestinal diseases (including post-operation cases) from being air-sick. The best preventive measure is to give hyoscine hydrobromide (1/100 gr.—0.65 mg.)* by mouth about an hour before flight, and to repeat this two hours later if necessary: for children the dose should be 1/200 gr. (0.32 mg.). Patients should be so advised and informed that after the first stage of the journey they will probably become acclimatized to flying and will not need any more tablets, unless bumpy weather is encountered. These anti-air-sickness tablets can be obtained from flight stewards and stewardesses in aircraft.

A number of factors predispose to air-sickness, such as fatigue, type of meal, noise, vibration, and cold. Advice should therefore be given regarding the need for sound rest the night before a flight, proper evacuation of the bowels, a light meal about an hour before taking off, and small light meals during the trip. In addition, those prone

to travel sickness should wear suitable clothing so as to be warm but not overheated and should protect their ears against aircraft noise by means of moistened cotton-wool plugs as provided on board. If they feel sick during flight they should be advised to relax and lie back in their seats, looking upwards, so as to minimize stimulation of the sensory hairs of the utricles by the otoliths (see Diagram)

Diagram to show position of otolith in the utricle in relation to vertical movements when the head is in various positions. Repeated vertical movements, whether accompanied or not by swaying, press the otolith on the sensitive nerve filaments in the floor of the utricle, leading to excessive stimulation and probably to travel sickness.

Travel Regulations

For international air travel the passenger has to carry certain inoculation certificates, depending on the destination and the countries to be traversed. The would-be traveller must have been vaccinated against smallpox within one to three years, and, if the journey is to be through a yellow-fever zone, immunized against that disease. Moreover, some countries still insist on inoculation against typhoid, typhus, plague, and cholera. Details of immunization requirements can always be obtained from the Medical Department, British Overseas Airways Corporation, Stratton House, Stratton Street, W.1 (tel.: Mayfair 6611, extension 134); these are published periodically in tabular form in the *British Medical Journal* under the heading "Air Travel." These requirements must be borne in mind when advising a patient regarding travel, as the immunizing procedure may have an adverse effect on the patient's condition.

The doctor concerned should see that the patient has all drugs and appliances necessary for the journey, and that he or she fully understands any action necessary en route. To this end, instructions should be written clearly. Apprehensive individuals and those who sleep badly when travelling should be given a sedative, which also will help to ward off travel sickness. If desired, the drugs and appliances can be handed to the chief steward of the aircraft for custody and control of medication. Air stewards and stewardesses have had a training in first aid and are normally in charge of the first-aid outfits. Any medical attendant or nurse required to accompany the patient must be provided by the passenger.

In any case of doubt the medical practitioner is advised to consult the appropriate airline medical authority—B.O.A.C., Stratton House, Piccadilly, W.1 (tel.: Mayfair 6611); B.E.A., Northolt Airfield, Middlesex (tel.: Ruislip 6061); B.S.A.A., Dr. J. C. Macgown, 21, Wimpole Street, W.1 (tel.: Langham 3243). To help the authority to make

* "Dramamine" (β -diaminoethyl benzohydryl ether 8-chlorotheophyllinate) is claimed by the Army Medical Department of the U.S.A. to be more efficient than hyoscine.

decision the medical practitioner should provide a statement covering the following points:

Name, age, address, and telephone number of invalid.....

 Diagnosis of condition.....
 Manifest symptoms.....
 Severity of disability (mild, severe)*.....
 Whether infectious or non-infectious.....
 Where under treatment—if in a hospital or nursing-home.....

 Nature of treatment.....
 Whether treatment effectively controls symptoms.....
 Whether treatment is necessary during the air journey.....
 Whether an attendant is necessary.....
 Whether patient can walk unaided.....
 Whether patient can travel in sitting position.....
 Any other points.....
 In my opinion..... is fit to travel by air
 from..... to.....

Signature of doctor.....
 Address and Tel. No.

Clinical findings referred to in a Table as possible limiting factors, including the systolic and diastolic blood pressures, should be added.

THE PHYSIOLOGICAL BASIS OF VAGOTOMY

BY

A. DAVIS BEATTIE, F.R.C.S., F.I.C.S.

Surgeon, Leicester General Hospital

The surgical treatment of peptic ulcer has recently become a matter of some controversy. The place held so long by subtotal gastrectomy in the treatment of all types of gastro-duodenal ulceration is now being challenged by vagotomy, and it is therefore of some importance that the physiological principles underlying the newer procedure should be generally appreciated.

Aetiology of Peptic Ulcer

There is little fundamental difference between the factors mainly responsible for gastro-duodenal ulceration and those producing similar lesions elsewhere. Trauma is probably the usual initiating factor; though toxæmia, localised vascular spasm, and even trophic neuritis may occasionally play a part in its onset. When an acute ulcer results from the action of one or more of these factors, the natural reparative processes of the body attempt to induce healing, but their action is opposed both by the physiological peristaltic activity and by the digestive nature of the gastric secretion. Dragstedt (1942) has shown that these alone are not sufficient to delay physiological healing and to lead to chronic ulceration in a normal individual. The stomach and duodenum are readily digested by pure gastric secretion, particularly if the latter has a high acid content, but they are rarely exposed to such action in a normal individual. The acid content of the stomach is actively low unless provoked by the presence of food, which itself acts as a diluent, and it is still further lowered during digestion by the periodic regurgitation of duodenal contents. Moreover, all living tissues display a considerable resistance to digestion by the gastric juices owing to the

protection afforded by their mucous surface secretions. It is only when these protective mechanisms are overcome that a typical peptic ulcer develops in experimental animals.

Past Attempts at Physiological Surgery

Hyperacidity has long been recognized as the main factor responsible for the abnormal persistence of the ulcerative process and the consequent development of a chronic ulcer. From the introduction of gastro-enterostomy by Wolffier in 1881, successive attempts have been made to deal surgically with this problem along physiological lines. None of them has proved entirely successful, however; even the various modifications of subtotal gastrectomy, which have so far formed the most certain approach, being not without certain drawbacks and a proportion of failures.

The rationale of these operations is the resection of a sufficient area of the acid-secreting portion of the stomach to prevent subsequent hyperacidity, and, since this will obviously vary from individual to individual, their success depends on striking a correct balance in each case. To leave too much stomach will obviously defeat the whole object of the procedure, whilst the removal of too much may lead to possible anaemia and the development of "small stomach" symptoms afterwards. The latter are, in fact, responsible for the majority of poor results following modern techniques, as the tendency is towards over-removal of gastric mucosa in an attempt to prevent subsequent ulcer recurrence. Recent figures show that a surprisingly high percentage of patients who have had apparently successful gastric resections are unfitted for full economic life afterwards by the intermittent gastro-intestinal upsets which follow and the impossibility of returning to normal dietetic existence.

Gastrectomy has other disadvantages also. The operative mortality, though surprisingly low in expert hands, is necessarily higher in the older age groups—the very patients in whom the complications of ulcer have themselves such a high death rate. Moreover, it is a mutilating operation and, while a physiological proceeding so far as the ulcer problem is concerned, leaves an unphysiological and deformed upper digestive tract in its wake.

The Ulcer Diathesis

The relative failure of all past surgical attempts to deal really successfully with peptic ulcer has recently resulted in careful reconsideration of the problem of the ulcer diathesis and its underlying factors.

It has long been recognized that a true ulcer diathesis does exist. The typical ulcer patient belongs to Goldthwait's (1915) asthenic type. He is a thin, lanky, narrow-chested individual with a "lean and hungry look"—driving, ambitious, emotional, and tense. The psychic make-up accompanying these physical characteristics often determines the choice of occupation, with the result that certain professions and trades—such as engineering, law, and surgery—are particularly ulcer-prone. There are, however, quite a number of ulcer patients who do not fall into this main group. These individuals belong more to the sthenic type. They may exhibit a most deceptive external calm and seem to keep their nervous stress hidden well beneath the surface. It is interesting, as Moore (1946) points out, that this type of individual tends to suffer from ulcers which bleed rather than from typical ulcer pain.

To whichever group the ulcer patient belongs, however, he shows the same reaction towards his environment. Most intelligent patients can correlate definite exacerbations of their symptoms with such events as prolonged nervous stress, fatigue, overwork, or irregular meal hours. Sex also seems to play a contributory part in ulcer development.

The relative incidence in males is rising steadily in response to the greater stress of modern life, which normally affects men more than women. In a series of 9,000 necropsies performed on chronic ulcer cases up to 1923, Stewart (1923) found chronic ulcer to be twice as frequent in males, and approximately the same sex-incidence ratio was present in 4,000 necropsies disclosing acute ulcer; whereas the admission rate to E.M.S. hospitals of ulcer cases for operation in the period 1942-3 shows a 10:1 male preponderance in the 15-35 age group and a 4.6:1 ratio in patients over that age.

It appears that the ulcer diathesis is rather the result of nervous stress on a particular psychosomatic type than a mere accident of physical build. This is further supported by the evidence of Simnitzky (1926, 1927) and Fokin (1925), who showed the presence of parasympathetic hyperactivity in a high percentage of peptic ulcer cases.

Results of Recent Research

A considerable amount of recent research has therefore been directed to the investigation of the mechanism through which this vagotonia modifies normal gastric secretion.

A. Influence of the Vascular Supply

Little work appears to have been done on the relationship between vascular supply and gastric secretion, but it is reasonable to suppose, as Le Veen (1948) points out, that it is similar to that of other glandular structures which have been more carefully investigated, such as the salivary glands and the kidney.

It has been shown in fully denervated experimental preparations of these organs that their secretion is directly proportional to the volume of blood flow; and it is known from work on the voluntary muscles and heart that muscle contraction is similarly dependent on its vascular supply. Since gastric secretion is undoubtedly increased by hyperperistalsis, vasodilatation of the stomach vessels may therefore influence it by both these mechanisms.

B. Chemical Factors

It was first shown by Komarov (1945) that when extracts of the pyloric antrum and the first part of the duodenum are injected into the blood gastric secretion results. This secretion, which is identical with the juice of the chemical phase of gastric digestion, differs from that of the nervous phase by its high acid content and relative deficiency in pepsin. It is unaffected by atropine, and must therefore result from a purely chemical stimulus to the gastric glands. The extract responsible for this response does not contain histamine, and its causal component appears to be a polypeptide known as "gastrin." There seems little doubt that this is in fact the normal mechanism by which the chemical phase of gastric secretion is produced, and that the latter is the result of the action of the absorbed products of the early nervous phase of digestion on the glands of the pyloric antrum.

Contributory evidence of the purely chemical action of this mechanism and of its lack of dependence on any neurogenic stimulus is provided by the results of antrectomy. This operation, in which the mucosa of the pyloric antrum and first part of the duodenum is resected without any other surgical procedure, results in profound modification of the secondary phase of the gastric secretion; whereas complete gastric neurectomy affects the latter only relatively slightly.

C. Influence of the Nerve Supply

The detailed work of Swann (1834), Kollmann (1860), McCrea (1924), and Mitchell (1940) on the anatomy of the vagus nerves has not yet found its way into the standard textbooks on anatomy. They form an intricate plexus on the thoracic oesophagus from lung roots to diaphragm, and

re-form into their main abdominal trunks only at the aortic level. They constitute the parasympathetic supply of stomach, small intestine, and caecum, and give branches to the liver, spleen, and pancreas. As in the case of sympathetic, they act on the bowel by modifying the tone of the two intestinal plexuses, which are primarily responsible for both movements and secretion.

The actual mechanism by which these plexuses operate is still imperfectly understood, but the work of Tyrrell-Gibson (1936) provides the most plausible explanation. He suggests that the primary movement of the bowel is a small recurrent rhythmical wave of contraction initiated by ganglionated cells of the plexuses. The presence of a fecal bolus simultaneously stimulates Auerbach's plexus, producing a deep peristaltic contraction behind it, and Meissner's plexus, resulting in a preceding wave of relaxation. Recent work on the "peristaltic gradient" of the intestine supports this hypothesis.

Modern research has added considerably to the knowledge of the function of the gastric nerve supplies. It was first suggested by Carlson (1913) and confirmed by McCrea (1924) that gastric peristalsis is governed entirely by the vagus acting through the local plexuses, and that the muscular "tonus," upon which the peristaltic movements are superimposed, is separately controlled by the sympathetic. McSwiney (1931) has shown that the sympathetic nerves carry both stimulator and inhibitor fibres, and McCrea's work indicates that the former are concerned with maintenance of gastric tone and the latter with peristalsis. The sympathetic is therefore not a true antagonist of the vagus, as is so often taught. The sympathetic supply to the stomach, as elsewhere in the body, controls the vascular tone, and it also forms the pathway for sensory impulses. Moore *et al.* (1946) have shown that painful stimuli can be produced by the inflation of an intragastric balloon after complete abdominal vagotomy. Latarjet's work proves that the pain of gastric crises, unaffected by vagotomy, ceases after complete gastric sympathectomy (Latarjet 1922; Latarjet and Wertheimer, 1923). Grimson *et al.* (1947) have demonstrated that the vagus does not carry sensory tracts, and Dragstedt (1947) has shown that recurrence of ulcer pain can be reproduced after complete vagotomy by the ingestion of sufficient quantities of strong hydrochloric acid. This work is in keeping with that of Bentley and Smithwick (1940), who showed that many of the afferent pathways from the duodenum, gall-bladder, and biliary tract are via the sympathetic supply of the organs.

It therefore seems probable that the sympathetic supply of the stomach and duodenum plays little part in the aetiology of peptic ulcer, apart from any secondary action such as that which may be produced by the local anaemia resulting from an abnormally high sympathetic tone. The vagal supply, on the other hand, is known to be directly concerned with gastric secretion, in addition to any indirect effect on this which it may produce through its action on peristalsis. The psychic secretion which precedes the ingestion of food is due to vagal stimulation of the gastric glands. The same reflex occurs within 10 to 15 minutes of "sham feeding," apart from any psychological stimulation, and is probably the result of a vagal reflex from deglutition and mastication. The gastric secretion which results from this psychic or neurogenic stimulation is present in both pepsin and hydrochloric acid, and persists for so long independently of the succeeding chemical phase.

Cushing (1932) showed the existence of a nerve pathway between the cerebral cortex and the upper gastro-intestinal region. From combined clinical and pathological evidence he showed that a definite nerve tract connected the va-

centres with the cortex, and that irritative lesions along this tract resulted in ulceration of the stomach and duodenum. He demonstrated, further, that this was due to hyperactivity of the vagal centres and that the same result was produced by the action of psychic stimuli on the area of cerebral cortex at which this tract began. His important work, the full implications of which have only recently been realized, confirmed the investigations of previous workers on experimental dogs. Stahnke (1924) had already produced typical peptic ulcers in these animals as the result of the increased neurogenic gastric secretion following vagal stimulation. Hartzell (1929) had shown that complete vagal section resulted in permanent reduction of the gastric acidity, though this effect was only transient if section was incomplete; and Beaver and Mann (1931) had completed this chain of evidence by demonstrating that the only dogs to escape peptic ulceration after a Mann-Williamson (1923) physiological gastro-enterostomy were those in which complete vagotomy had also been performed.

The neurogenic secretion of gastric juice is not entirely limited to psychic stimulation, although Pavlov's (1910) original views to this effect are still regrettably present in many textbooks. Carlson (1923) showed, after intensive animal and clinical experiment, that there is normally a small continuous secretion of gastric juice even in prolonged fasting, and that this secretion is of the same type as that of the psychic phase of normal digestion though less in degree. Dragstedt and Schafer (1945) showed that this secretion was present to an excessive extent in the typical ulcer patient even during sleep, and that it was accentuated in emotional states and nervous stress. Wolf and Wolff (1942), studying a man with a permanent gastric fistula and complete traumatic oesophageal occlusion, have shown that the excessive acid secretion resulting from emotional conflict produces typical ulcer symptoms associated with definite changes in the gastric mucosa. When such physiological stimuli were prolonged the consequent hyperchlorhydria resulted in intense mucosal hyperaemia, with the development of small petechial haemorrhages, and the affected mucosa showed an increased tendency to macroscopic erosions through quite trivial trauma. If these erosions were then exposed to free hydrochloric acid small acute peptic ulcers rapidly developed.

The Development of Vagotomy

An analysis of all this evidence suggested that the most rational physiological approach to the problem was to be found in vagotomy, and a number of attempts had been made along these lines before Dragstedt and Owens's first reported successes. Most of these had been made through an abdominal approach and were reviewed by Hartzell (1929). The first transthoracic approach was made by Pieri and Tanferna (1930), but their cases were not uniformly successful, and it was left to Dragstedt and Owens (1943) to elaborate a suitable technique. A year later Dragstedt (personal communication) was also the first to evolve the modern abdominal approach, which he afterwards described in detail. Since then a voluminous literature from many sources has grown up on the technique and after-results of vagotomy, and a great deal of detailed research has been made into the physiological end-results of this operation. Nearly 1,500 successful cases have now been reported from the U.S.A., Scandinavia, and Britain alone, so that the operation can no longer be considered an experimental method of treatment.

The majority of surgeons employing vagotomy confine its use to the treatment of uncomplicated duodenal ulcer in the younger age groups, and of recurrent ulceration

following more radical procedures. But there is a strong case for carrying it out as a routine, as a concurrent procedure, whenever gastrectomy or gastro-enterostomy is performed for peptic ulceration; and I believe that it may also have a place as the sole treatment of some types of gastric ulcer. There is a justifiable tendency to avoid vagotomy in gastric ulcer through fear of later malignant change or of missing early carcinomata. But this does not apply in the same degree to small subacute lesions of the lesser curvature which fail to respond rapidly to energetic medical treatment, or to the high cardiac ulcers which are otherwise so difficult to deal with surgically. My own series of more than 160 vagotomies includes a number of successful operations in this type of case.

Apart from the effects on the stomach and duodenum, which are described below, division of the vagus nerves appears to produce few physiological sequelae in the other abdominal viscera. It has been shown by several investigators, including Ivy (1934), that vagotomy is followed by a slightly decreased secretion of bile and pancreatic juice; Pfeiffer *et al.* (1940) have described a temporary post-operative drop in blood calcium similar to that found to occur in experimental dogs; and the occasional occurrence of the "dumping syndrome" after operation suggests that there may also be some temporary alteration in the amount of insulin secreted. But all these are minor effects, and the absence of any more definite sequelae is in accordance with the clinical results following high subtotal gastrectomy and lower oesophagectomy, in which a concurrent complete abdominal vagotomy is almost always unwittingly carried out.

Clinical Results of Vagotomy

The most dramatic effect of vagotomy is the immediate relief of all pain and other ulcer symptoms, together with a rapid increase in weight. The psychological reaction of the patients after operation is highly satisfactory, and the majority of them are enabled to return to full economic life within six weeks.

There has been no proved case of ulcer recurrence following a complete neurectomy, as checked by insulin test meal. This test, first described by Hollander (1944), depends on the fact that the hunger pains consequent on hypoglycaemia are associated with excessive gastric secretion. This was originally demonstrated by Roholm (1930); and Okada *et al.* (1929) and La Barre and de Cesp  des (1931) showed that the hypersecretion is dependent on the integrity of the vagal pathway. The acid response of the stomach is very great where this pathway is normal, but it is abolished after complete vagotomy. As might be expected, another effect of vagotomy is to lower both the total volume and the acidity of the gastric secretion. Thornton *et al.* (1946) and Grimson *et al.* (1946) have both drawn attention to these changes in the night fasting juice, which are similar to those previously described by Hartzell in the fractional test meal. I have shown that the free hydrochloric acid secreted during a fractional meal test is reduced to one-third of the pre-operative quantity, but that the general character of the curve remains otherwise unaltered (Beattie, 1948). This drop in acidity is undoubtedly the main factor responsible for the disappearance of the previous ulcer diathesis after vagotomy.

As the result of the immediate paralysis of the stomach and small intestine, which only gradually recover their tone and power of movement, certain unpleasant retention symptoms occur. Almost complete gastric paralysis persists for two to three days and peristalsis then gradually returns, though it probably never reaches the same frequency and amplitude as previously. Moore *et al.* (1946) and Grimson *et al.* (1947) have investigated this subject

by means of repeated radiological examinations and pressure-recording intra-intestinal balloons. The latter workers have shown that there also is a gradual increase in muscle tone, which may reach two or three times its pre-operative strength within three years. Despite this, however, some degree of gastric dilatation often occurs—the probable result of pylorospasm from the unopposed action of the sympathetic nerve supply at the pylorus. This has been checked radiologically by Moore *et al.* (1946) and by Lawson (personal communication), and it has been shown by Grimson *et al.* (1947) that similar minor alterations in muscle tone and movement also occur in the duodenum and jejunum.

In addition to the immediate gastric paralysis there is nearly always some degree of temporary dysphagia following operation. This is the result of cardiospasm secondary to the trauma inflicted on the lower oesophagus and to interference with its nerve supply. It always passes off spontaneously within a few weeks, but while it exists it increases the tendency to gastric distension already present by the aerophagy which it encourages.

These retention phenomena, which present themselves clinically as occasional attacks of flatulence associated with eructation of foul gas towards evening or in the early hours of the morning, may be accompanied by mild regurgitant vomiting and followed by transient diarrhoea. In the majority of cases they are relatively mild and are regarded by the patient as of only minor importance, but they may be more severe and last for many months. They tend to subside eventually as the stomach recovers its tone and peristalsis, but may be so persistent that further operation becomes necessary. Dragstedt (personal communication) has pointed out that even in the milder cases there is a tendency for similar attacks of the same character to occur throughout the subsequent lifetime of these individuals. Such attacks occur during the same emotional crisis and nervous stress as would previously have produced ulcer exacerbations, and are probably due to the unopposed action of the sympathetic system in the new gastro-intestinal response to the nervous impulses consequent on psychic stimuli.

Recent work on certain choline derivatives has produced drugs which have a relatively selective action on the gastro-intestinal part of the parasympathetic system, and I have found the administration of these to be of value in reducing the severity of the retention symptoms in some cases. Unfortunately they do not yet appear to be equally effective in all instances, though it seems probable that further research in this direction may eventually prove more successful.

Conclusion

There seems little doubt that the final solution to the ulcer problem lies along medical lines. It should not be beyond the limits of future possibility for suitable drugs to be developed to control the vagotonia which is the underlying cause of the ulcer diathesis.

Till then, however, the failure of medical treatment in a certain proportion of cases will continue to result in chronic ulceration, which can be dealt with successfully only by surgical means. There is little doubt that vagotomy will ultimately come to be accepted as the routine surgical treatment for chronic duodenal ulcer and for the complications of anastomotic and jejunal ulcer after gastrectomy or gastro-enterostomy. It may even find a place in the treatment of some varieties of chronic gastric ulcer. It has a much lower operative mortality and post-operative recurrence rate than the more radical procedure of gastrectomy, and gives a higher proportion of full economic successes. But it is still relatively in its infancy, despite the

six-year post-operative records of the earlier cases that are now available; and it requires further technical development to eliminate its occasionally severe retention sequelae before it can be regarded with complete confidence.

NOTES ON EXPERIMENTS ILLUSTRATING NORMAL TEMPERATURE REGULATION IN YOUNG MEN

BY

SAMSON WRIGHT, M.D., F.R.C.P.

John Astor Professor of Physiology, Department of Physiology
Middlesex Hospital Medical School

It has been the custom for some years in the department of physiology for our students to carry out a series of experiments which illustrate some of the more important facts about body temperature and its regulation in man. The experiments are conveniently performed during the vacation in the student's own home, as they require no special apparatus but do need a good deal of time and access to a bathroom. In this paper brief particulars are given of these experiments for the benefit of teachers who might care to use them. Some illustrative results are also shown graphically; most readers may find these graphs more instructive than a statistical analysis of the results. All the observations on which this report is based were carried out on healthy young men during the summer vacation; the readings are given in °F. I am greatly indebted to the students whose results I have used.

Temperature in the Mouth, Groin, and Axilla

The subject, using a so-called "half-minute" thermometer, is instructed to read the temperature at half-minute

intervals at these sites until a steady maximum reading is obtained; this maximum is an approximate measurement of blood temperature. Two illustrative sets of curves are given in Fig. 1. They show that in the mouth the steady maxi-

FIG. 1.—Time taken to get a constant temperature reading in mouth, groin, and axilla.

mum is attained after some three or four minutes, while in the groin and axilla a longer time is necessary—up to five or even seven minutes. The curves also show the well-known fact that generally the maximal temperature in the axilla is lower by 1°F (0.55°C) or more than that in the mouth; the maximal temperature in the groin approximates more closely to that in the mouth.

It is perhaps unfortunate that the clinical thermometers in common use have inscribed on them "half-minute" or "two minutes." The person using the thermometer is thus misled into believing that when it is kept in the mouth or elsewhere for the specified time it records accurately the body (i.e., the blood) temperature. The figures on the thermometer do accurately indicate its physical properties under specified test conditions outside the body; thus the figures give the time that it takes the thermometer to record accurately the temperature in a thermostatically controlled bath of water. But when the thermometer is used clinically under very different physical conditions we must allow enough time to elapse to permit the thermometer in the mouth, groin, or axilla to attain temperature equilibrium with the blood; the curves in Fig. 1 show that the thermometer must be kept in position for three minutes or longer to achieve this end.

I venture to suggest that clinical thermometers should be relabelled as "rapid" and "slow" to indicate their relative physical sensitivity, and that the thermometer should be inscribed with an instruction that it should be kept in the mouth for not less than three minutes or until a constant temperature reading is obtained. I fully appreciate that if such instructions were faithfully followed it would take one nurse equipped with one clinical thermometer nearly one hour to record the temperature of ten patients; but this difficulty could be overcome by using several clinical thermometers simultaneously or, as suggested by a correspondent in the *Lancet*, by recording the temperature only of those patients in whom temperature disorders are known to be present or are suspected. It is obviously undesirable for the nursing staff to spend a good deal of time carelessly taking many inaccurate readings. The same remarks apply to temperature-recording in a busy surgery or during the rush of home visits.

Effect of (i) Hot and (ii) Cold drinks on Mouth Temperature

(i) The subject is told to drink one cup of hot tea, and in a second experiment two cups, at a temperature of $140\text{--}150^{\circ}\text{F}$ ($60\text{--}65.5^{\circ}\text{C}$). (ii) The subject is told to drink 1 litre of ice-cold water. In each case the mouth temperature is read at half-minute intervals until it returns to the control level; in these experiments the "half-minute" thermometer used is initially recording changes in the temperature of the mucous membrane of the mouth and not changes in blood temperature.

(i) Fig. 2a shows that after one cup of hot tea the mouth temperature may rise rapidly to 101.4°F (38.55°C), and after two cups to 102.6°F (39.2°C). It then falls to control level in five minutes after one cup and in about

FIG. 2a.—Effect of a hot drink on mouth temperature.

eight minutes after two cups of hot tea. A hot drink may thus sometimes be the cause of an unexplained clinical "pyrexia."

(ii) Fig. 2b shows the effects of drinking the cold water as quickly as possible, and Fig. 2c of drinking it over a period of 12 minutes. The mouth temperature may fall

FIG. 2b.—Effect of a cold drink on mouth temperature.

FIG. 2c.—Effect of a cold drink on mouth temperature.

from 97.8 to 95°F (36.55 to 35°C) or less; it remains round about this low level for 8 to 20 minutes and slowly recovers as the oral mucosa is warmed up again by the circulating blood.

Diurnal Variation

The subject is asked to record his mouth temperature every hour throughout the day and night for 72 hours, taking the precautions called for from the preceding observations. In quite a number of cases the instructions were followed literally. The only way to get regular night readings is to have at the bedside an alarm clock suitably set to wake the subject up each successive hour. The value of the temperature readings is considerably enhanced if a careful note is made at the time of what the subject is doing, with special reference to work, food, sleep, room temperature, heart rate, and respiration. Illustrative records are set out in Figs. 3a, 3b, and 3c.

FIG. 3a.—Diurnal variation of body temperature.

FIG. 3b.—Diurnal variation of body temperature in relation to external temperature and bodily activities.

FIG. 3c.—Diurnal variation of body temperature and heart rate.

Such experiments are of great value in teaching the student the extent of the range of the normal, in himself and his friends, of several so-called "physiological constants." The student also learns to appreciate the fundamental difference between an average value and a normal range, a distinction which is of the utmost importance in many branches of physiology and medicine. The examples of diurnal variation here illustrated show in Fig. 3a a range between 99.2 and 96.2° F. (37.3 and 35.7° C.), in Fig. 3b between 99.2 and 96.5° F. (37.3 and 35.85° C.), and Fig. 3c between nearly 98 and 95° F. (36.7 and 35° C.). A daily fluctuation of 3° F. (1.66° C.) may thus occur in any one normal person. The possible extent of the "tolerated" daily fluctuation is not fully appreciated, because it is very unusual to take records steadily during the night, and it is commonly at the inconvenient hours of 2 to 6 a.m. that the minimum temperatures are generally observed.

Fig. 3c shows a beautiful correlation between mouth temperature and heart rate, incidentally confirming the well-known clinical dictum that the heart rate varies by 10 beats per minute for every 1° F. change in body temperature. The curves also illustrate the wide range of the heart rate in a normal person even at rest; the range at rest in this instance is from a so-called "bradycardia" (pulse rate of 60) to a "slight tachycardia" (pulse rate of 90), according to the time of day and the associated body temperature.

Fig. 3b shows that the diurnal variation is fundamentally related to the rhythm of sleeping and waking. The temperature falls progressively during the earlier hours of sleep, but begins to rise once more in the later hours. In this example there seemed to be a considerable relationship between the variations of external temperature and those of body temperature.

The question may be fairly asked: Why have a mark on clinical thermometers opposite 98.4° F. (36.9° C.)? In one person such a temperature at any time of the day may represent pyrexia; in another the maximum normal temperature may be almost 1° F. higher. A mark of this sort probably misleads the public into supposing that a temperature reading over 98.4° F. at any time represents pyrexia; in time even the doctor may begin to believe that too. It might be better to have no mark on the thermometer at all and rely on suitable instructions being given to the public. It might be explained that a temperature over 99.5° F. (37.5° C.), taken with the precautions previously explained, probably represents pyrexia; but it should also be made clear that ideally one should be familiar with a person's temperature range in health, because in people with a lower temperature range an apparently "normal" temperature reading may represent pyrexia.

Effect of a Hot Bath on Temperature, Respiration, and Heart Rate

The subject gets into a hot bath and stays in it for about five or six minutes; observations are made while in the bath and after getting out of the bath until the control

FIG. 4.—Effect of a hot bath on body temperature, respiration, and heart rate.

levels are reached. Fig. 4 shows that in a bath at 110° F. (43.3° C.) the mouth temperature may rise from about 97.8° F. (36.55° C.) to over 100.3° F. (37.95° C.); the heart rate may increase from 75 to 115 and the respiration rate from 12 to 28 per minute. Mouth temperature may subsequently take some 30 minutes to return to normal though respiration and heart rate recover rather more rapidly.

This experiment shows clearly the limitations of normal temperature regulation, and how it can break down quickly under conditions of stress. In a bath at 110° F. (43.3° C.) heat is being taken up by the immersed part of the body and heat loss depends mainly on evaporation of sweat from the exposed part of the body. As the atmosphere in the bathroom is very humid, evaporation of sweat is probably minimal. Body temperature is therefore raised by the heat released by the metabolism as well as by the heat taken up from the surrounding medium. This experiment is of clinical interest in showing that the body and mouth temperature may be raised for a considerable time after a hot bath.

Effect of Exercise

The subject is asked to take a sharp

FIG. 5.—Effect of exercise on body temperature and heart rate.

rate from 60 to 125. Severe exercise in a hot, humid climate may produce pronounced pyrexia.

Effect of (i) Standing Naked in Front of a Window for 20 Minutes and (ii) a Cold Bath

(i) These experiments were all conducted in the summer, when the external temperature was of the order of 60° F. (15.5° C.). Fig. 6a shows a number of results. Usually the fall of

FIG. 6a.—Effect on body temperature of standing naked in front of an open window for 20 minutes.

FIG. 6b.—Effect on body temperature of a cold bath at 56° F. (13.3° C.).

35.85° C.). Fig. 6a also shows that sometimes, during the period of exposure to cold, body temperature may rise by nearly 1° F., presumably because of an overswing of the compensatory mechanisms.

Fig. 6b shows the modest temperature-lowering effect of a cold bath at 56° F. (13.3° C.).

Summary

Simple experiments are described which illustrate the more important facts about normal temperature and its regulation in man.

Attention is drawn to the undesirability of having a mark on clinical thermometers opposite the 98.4° F. (36.9° C.) level, and of inscribing clinical thermometers with the words "half-minute" or "two minutes."

The Nursery School Association has started a new quarterly magazine called *Young Children* with the purpose of fostering a fuller understanding of children. The first number includes some of the evidence given by the late Dr. Susan Isaacs before the Curtis Committee. The price of the magazine is 1s. 6d.; it is obtainable from the Association at 1, Park Crescent, Portland Place, London, W.1.

USE OF DIPARCOL IN PARKINSONISM

BY

R. S. DUFF, M.B., F.R.F.P.S., M.R.C.P.

Late Medical Registrar, Southern General Hospital, Glasgow

A synthetic drug, "diparcol" (diethylaminoethyl-N-thio-diphenylamine hydrochloride), was found useful in the treatment of all forms of Parkinsonism by Sigwald *et al.* (1947) and by Bovet *et al.* (1947) in France. A limited supply was made available at this hospital by the courtesy of the manufacturers, May and Baker, Ltd., and a clinical trial of the drug was carried out in eight cases of post-encephalitic chronic Parkinsonism of varying degrees of severity. A ninth case, of malignant hypertension with the Parkinsonian syndrome, was given the drug for a short time before death; its effect, if any, could not be assessed, and the case was excluded from the series.

It is notoriously difficult to provide satisfactory criteria of change in the state of patients suffering from chronic disorders of locomotion. Evaluation of treatment therefore depends to a large extent upon the subjective opinions of the physician and of the patients and those around him, but it is advantageous to base opinions so far as is possible upon objective measurements. Carmichael and Green (1928) devised an apparatus to measure rigidity in resting limbs, and used the ergograph to record the performance of simple repetitive motions rather than of individual movements; but in the present study an attempt was made to consider each patient in terms of the following ten modal activities, which together involve automatic, impulsive, and deliberate movements of different degrees of complexity: (1) turning in bed, rising from and returning to bed; (2) dressing and undressing; (3) performance of the toilet, especially shaving in men; (4) eating; (5) walking; (6) turning around corners; (7) climbing stairs; (8) speaking; (9) writing; and (10) movements of facial expression as reflecting mood and interest.

The procedure was to observe each patient over a period of two to three months while they were receiving adequate dosage of the customary drugs (stramonium, hyoscine, belladonna) in such combination as produced the maximum benefit. In each patient the state of the ten modal activities varied, but an attempt was made to assess the efficiency of each according to the following scale:

- 0 = No activity on account of contractures or rigidity
- 1 = Activity grossly restricted or completely ineffective
- 2 = Moderate restriction, especially by rigidity
- 3 = Moderate restriction, especially by tremor
- 4 = Activity approaching normal, but slow and clumsy
- 5 = Activity practically normal, or at least effective

Throughout the test any lasting changes in the tremor or hypersalivation were recorded, but it was felt that little was to be gained from the observance of minute changes, especially in tremor, which so noticeably varies from hour to hour with the attitude and mood of the patient. In view of the failure of several authorities (Neal *et al.*, 1942) to find regular amelioration of oculogyric crises by treatment otherwise effective, a particular note was taken of the incidence of these and of "emotional" and "laryngeal" crises.

Diparcol was then given according to the scheme first recommended by the manufacturers, dosage being gradually built up over a period of five to six weeks, with simultaneous gradual withdrawal of the solanaceous drugs. Except in Case 1, the drug was given in the full dosage of 1 g. daily for a period of ten weeks, after which the effect of slightly varying the dose was studied. When the

most beneficial dosage was found, each case was reassessed in terms of the ten modal activities, and improvement or deterioration recorded. Slight improvement meant an increment of 1 unit, considerable improvement 2 units; conversely, slight deterioration was measured by a down-scaling of 1 unit, and so on. The results are shown in the table.

Modal Activity	Case 1		Case 2		Case 3		Case 4		Case 5		Case 6		Case 7		Case 8		Net Change
	A	B	A	B	A	B	A	B	A	B	A	B	A	B	A	B

Writing ..	0	0	3	3	2	2	2	2	2	2	0	0	4	4	2	3	1+
Facial expression and mood ..	0	0	3	4	4	5	2	3	2	3	0	2	3	4	3	4	8+
Total change in each patient ..	2+		8+		8+		6+		9+		8+		8+		9+		58+
Notes and clinical impressions	Died during treatment		Striking benefit		Considerable benefit		Fainting turns		Fairly severe case gaining benefit		Subjective improvement marked. Bedridden		Moderate benefit		Salivation aggravated		

A = During control period with solanaceous drugs. B = During period of administration of diparcol. 0 = No activity. 5 = Practically normal activity.

In order to reduce the suggestive influence of a new and promising treatment three patients (Cases 2, 3, and 8) were gradually returned to the former regime of the solanaceous drugs, whereupon a notable relapse occurred, while reintroduction of diparcol once more brought favourable results. The substitution of inert tablets, mixtures, or injections to provide a control in the treatment is rarely of value, inasmuch as patients with even a mild degree of Parkinsonism soon become aware of the deception.

Results of Treatment

As will be seen from the table, all the patients derived a little benefit from diparcol as compared with previous treatment. Except in Case 1, in which death occurred suddenly, the numerical benefit in each case was about equal; this contrasts with the erroneous clinical impression that had been gained that the less severely affected patients were the most improved. The reason for this impression was the striking facilitation of normal or almost normal activities in those in whom such activities had been only slightly or moderately restricted. The importance of thus evaluating and tabulating the results is manifest.

In general it would seem that the more skilled activities, such as writing, walking round corners, and climbing stairs, were improved to a smaller degree than more "primitive" acts like turning in bed or eating, but such generalizations are hardly justified in such a small series.

Improvement in the feeling of well-being was quite noteworthy in several patients; this was to some extent included in the tenth modal activity (expression).

In respect of ambulant patients any improvement, however small, in the performance of simple domestic or social tasks represents a considerable boon. The loosening up of a rigid bedridden patient, while less spectacular, was reflected in a decrease in nursing requirements.

Oculogyric crises were not significantly influenced by the drug, but in one patient there seemed to be relative freedom from "laryngeal crises" during the administration of full doses.

Undesirable Effects.—(1) Hypersalivation was not well controlled by diparcol in four of the cases, in which the addition of small doses of belladonna became necessary. (2) Faintness and "fainting turns" occurred in two patients,

but were absent when the dosage was slightly reduced. (3) Paraesthesiae consisting of creeping or burning sensations referred to the head and upper trunk were mentioned by two patients. This feature tended to pass off after reassurance, despite continuance of the drug. (4) Transient blurring of vision was noted in one case. (5) Undue drowsiness was complained of by one patient: three others

reported that they were sleeping better. (6) Weekly blood counts were carried out in half the cases in view of the death of one of Sigwald's patients from agranulocytosis (which was not thought to be related to treatment by the drug). There was a tendency for the white cell count to fall to 4,000 per c.mm. during the initial weeks, with subsequent rise to former levels. No case of true leucopenia occurred. In one patient a slight iron-deficiency anaemia was noted; this responded well to ferrous sulphate.

Illustrative Case Histories

Case 1.—A debilitated woman aged 30 was suffering from progressive Parkinsonism which followed an attack of encephalitis lethargica at the age of 7. She was almost completely bedridden on account of rigidity of the limbs and trunk; the upper limbs were maintained in flexion, with the lower limbs partially extended. Hypersalivation and seborrhoea were excessive, and she was subject to frequent oculogyric and laryngeal crises; speech was infrequent and practically unintelligible. After receiving diparcol for a month, with little benefit, she developed pyrexia associated with respiratory symptoms and was taken off that drug, full doses of stramonium and hyoscine being substituted. Five days later she died suddenly. Necropsy revealed only bronchopneumonia, but it was noted that rigor mortis of the viscera had persisted longer than usual. According to Hall (1943), sudden unexpected death is not rare in young women with Parkinsonism. Perhaps the sudden withdrawal of the diparcol resulted in a paroxysmal autonomic crisis leading to fatal peripheral circulatory failure and bronchopneumonia. Similar crises have been reported by Ostow (1943) and Oller (1946).

Case 2.—A labourer aged 36 first developed oculogyric crises at the age of 29, after which the full Parkinsonian picture slowly became manifest. He was ambulant, but experienced particular restriction of fine movements, largely from rigidity. His general health was good. Following treatment with diparcol he obtained uniform benefit in almost all locomotor functions, gratefully attested by his relatives. During the administration of large doses he complained of occasional paraesthesiae and faintness. Only laziness prevented him from undertaking simple remunerative employment.

Case 8.—A retired lamp-lighter aged 64 had suffered from encephalitis lethargica in 1919 at the age of 35. Considerable disability of gait had been present for at least three years, together with gross tremor and rigidity of the limbs, which considerably restricted all motor activities. Rigidity of the trunk, which prevented his turning in bed at night, was a constant source of annoyance to him before receiving diparcol.

Fairly uniform amelioration of his rigidity brought much satisfaction, although tremor was not noticeably abated and an excess of mouth-dribbling demanded the addition of belladonna. This patient, whose general physical state was below normal, developed an anaemia which responded to iron. He complained also of transient blurring of vision while receiving diparcol.

Conclusions

Diparcol seems to offer some advantages over the tropane series of alkaloids (exemplified by stramonium) in the treatment of Parkinsonism of all grades.

It is advisable to start with small doses, and gradually to increase dosage up to a maximum of 1 g. daily until significant benefit is obtained. Withdrawal of the solanaceous drugs should be correspondingly slow; indeed, it is probably wise not to deprive patients of belladonna or stramonium completely.

It was found that treatment with two 0.25-g. tablets upon waking, followed by one tablet at noon and one at about 5 p.m., brought the greatest reduction of rigidity, there commonly being a spontaneous improvement (apart from treatment) in the evening.

Summary

The advantageous and untoward results of the drug diparcol in the treatment of eight cases of Parkinsonism are reported, and the use of the drug is discussed.

A method of recording and evaluating the results of treatment of patients with chronic disorders of locomotion is described.

I am happy to acknowledge my indebtedness to Drs. Snodgrass, Ostler, and Scott, under whose care the patients were treated, and to Dr. Mackay for permission to publish.

SUCCESSFUL TREATMENT OF TYPHOID CARRIER WITH PENICILLIN AND SULPHAMERAZINE

BY

C. A. RUMBALL, M.R.C.P., D.P.M., D.T.M.&H.
K.H.P.

Group Captain, R.A.F.

AND

L. G. MOORE, M.B., B.Ch., B.A.O.

Squadron-Leader, R.A.F.

(From Princess Mary's R.A.F. Hospital, Halton, Bucks)

The problem of treating the chronic faecal carrier of typhoid fever has always been unsatisfactory. Infection of the gall-bladder (Boyd, 1944) is one of the most important features of the chronic carrier state. It forms the basis for advising cholecystectomy in an effort to eradicate bowel infection in chronic faecal carriers; but cholecystectomy is not uniformly successful for this purpose, and there are many who have submitted to the operation without deriving the anticipated benefit. It is clear that the gall-bladder is not the only focus in the alimentary tract where chronic infection can reside for many years.

The combination of sulphathiazole and penicillin was advocated by Bigger (1946), who noted, during *in vitro*

experiments, that a combination of 4 units of penicillin and 10 mg. of sulphathiazole per 100 ml. would sterilize broth containing 70,000 typhoid bacilli per ml., and that one unit of penicillin and 10 mg. of sulphathiazole would sterilize broth containing 7,000 typhoid bacilli per ml.

Based upon Bigger's observations, the combination of penicillin and sulphathiazole has been tried during the acute typhoid illness and upon the chronic carrier state. The result of therapy during the acute illness has been disappointing; some observers record no improvement, though McSweeney (1946) noted that the toxæmia appeared to be lessened and that there were no complications due to ulceration of the bowel.

The successful treatment of two chronic faecal typhoid carriers, one of whom had previously submitted to cholecystectomy without change in his carrier state, was reported by Comerford, Richmond, and Kay (1946), who subsequently had the opportunity of carrying out a necropsy (Comerford, Richmond, and Kay, 1947) upon one of these patients who died from an unconnected cause. No cultures of *Salmonella typhi* were obtained from gut, biliary tract, urinary tracts, spleen, or lungs.

Fry, Jones, Moore, Parker, and Thomson (1948) treated 17 faecal typhoid carriers with massive doses of penicillin and moderate doses of sulphathiazole. They reported apparent cure in only three cases.

We would like to record a case treated with two separate courses of penicillin and sulpha drug, in which failure attended the first course, when the blood level of sulpha drug was low, and success followed the second course, in which it was high: the total penicillin dosage was practically the same in each course. It seems possible that previous failures by one of us (C.A.R.) in similar cases may be explained by an inadequate blood concentration of sulpha drug.

Case Report

A corporal aged 24 contracted severe typhoid fever in Egypt in January, 1946. He developed a faecal carrier state, for which he was given full doses of sulphathiazole (the exact amount was not stated), but there was no change in his carrier state. He was released from the R.A.F. eight months later, and was notified to his M.O.H. as a faecal carrier. He rejoined the R.A.F. the following year without disclosing that he was a chronic carrier. He had remained well, and had put on 2 stone (12.7 kg.) in weight.

In November, 1947, when examined for fitness for service abroad, he volunteered the information that he was a chronic carrier. His stool culture yielded a profuse growth of *Salm. typhi*, and he was admitted to this hospital. He was physically fit. Blood sedimentation rate, 3 mm. in 1 hour (Westergren). Fourteen daily specimens of urine yielded no typhoid bacilli. *Salm. typhi* was isolated from his bile obtained by duodenal intubation, and from consecutive specimens of faeces. Agglutinations were negative with "O" suspensions of *Salm. typhi* and *Salm. paratyphi* A and B, but gave a 1 in 20 agglutination with a VI suspension of *Salm. typhi*.

The man was anxious to remain in the R.A.F., but considered that cholecystectomy was too high a price to pay. In view of the uncertainty of response in clearing up the carrier state by surgery his refusal seemed reasonable. It was decided to try the effect of combined sulphamezathine and penicillin. Stools were examined immediately before beginning therapy and a profuse growth of *Salm. typhi* was isolated.

He was given 500,000 units of penicillin intramuscularly at four-hourly intervals, and 2 g. of sulphamezathine orally for two doses, followed by 1 g. four-hourly to a total of 32 g. Blood levels of sulphamezathine were carried out to determine the minimum concentration, which was anticipated to occur six hours after an oral dose of the drug. This assay showed 1.5 mg. of free sulphamezathine and 1.8 mg. of total sulpha drug per 100 ml. of blood. On completion of treatment the stools yielded a profuse growth of *Salm. typhi*.

Failure was attributed to the low blood levels of sulphamezathine, and it was decided to repeat the course, using sulphamerazine in place of sulphamezathine, since it allowed higher blood concentrations to be reached without excessive dosage. For various non-medical reasons nearly two months elapsed before starting the second course on Feb. 2, 1948.

Sulphamerazine, 2 g., was given orally at eight-hourly intervals for two doses, and subsequently 1 g. eight-hourly for seven days, to a total of 25 g. Penicillin, 400,000 units intramuscularly, was given concurrently three-hourly night and day, to a total of 24,000,000 units for the same time.

Assay of the blood for penicillin, tested three hours after an injection, yielded a concentration of 3.2 units of penicillin per 100 ml. of blood.

Assay of the blood for sulphamerazine, tested at eight hours after an oral dose—i.e., just before the next dose—yielded a concentration of 12 mg. of total sulphamerazine and 7 mg. of free sulphamerazine. Stools were cultured daily for fourteen days after cessation of the course, and all were negative for *Salm. typhi*. Stool examinations were continued for the next nine months; three daily specimens were pooled and examined each week, making a total of 117 stools cultured.

All cultures were negative for *Salm. typhi*, and it seems probable that the patient has been freed from the carrier state, though he will remain under observation for a further three months to complete a year's observation. It is noteworthy that his agglutination titre against a VI suspension of *Salm. typhi* had fallen from 1 in 20 to nil.

Discussion

The largest series of faecal carriers submitted to the synergistic action of penicillin and sulphathiazole consists of 17 cases reported by Fry *et al.* (1948); of these only three remained negative for long periods—two were still negative at 36 weeks and one at 48 weeks. Eight of their failed cases received a course identical with that successfully employed by Comerford *et al.* (1946) upon two cases. Such evidence suggests that the result of treatment is capricious and unpredictable.

Success in a single case has no particular significance, and it is published only because it may draw attention to the value of estimating blood levels during treatment. It is difficult to avoid the conclusion that blood sulpha levels in excess of 10 mg. per 100 ml. may be necessary to obtain the synergistic effect of penicillin. It is possible that the same therapeutic doses may give different blood levels in different individuals, and what seems an adequate oral dose may not create an adequate blood concentration. Sulphamerazine has the merit of giving high blood levels with moderate oral doses, and it has a minimum of unpleasant side-effects.

It is suggested that in any future series of cases treated by combined penicillin and sulpha drug the blood levels should be estimated during treatment to note what relation exists between blood concentration and successful treatment.

We wish to thank Air Marshal P. C. Livingston, C.B., C.B.E., F.R.C.S., K.H.S., Director-General of Medical Services, Royal Air Force, for permission to publish this paper.
